Geological Society, June 24.—Sir Archibald Geikie, F R S, President, in the chair.—The following communications were read.—On wells in West Suffolk boulder-clay, by the Rev Edwin Hill. It might be supposed that in a boulder-clay district water could only be obtained from above or from below the clay. But in the writer's neighbourhood the depths of the wells are extremely different, even within very short distances, and since the clay itself is impervious to water, he concludes that it must include within its mass pervious beds or concludes that it must include within its mass pervious recessor seams of some different material which communicate with the surface. It would follow that this boulder clay is not a uniform or a homogeneous mass. The visible sections are only those given, at hand by ditches, and at a considerable distance north and south by pus at Bury St. Edminds and Sudbury The appearances in ineee narmonize with that conclusion. Consciu-tion and appearances differ from what we should expect on the theory that this boulder clay was the product of the attrition between an ice-sheet and its bod. The reading of this paper was followed by a discussion in which Priof Pretwick, Dr. Evans, Mr. Clement Read, Mr Charlesworth, Mr Topley, Mr. Goodchild, the President, and the author took part —On the metaphyres of Caradoc, with notes on the associated felsites, metaphyres of Caradoc, with notes on the sas-clasted felates, by Frank Rulley—Notes on the goodoys of the Tonga Islands, by I. THURSDAY, JULY 16, 1891.

ORGANIZERS OF TECHNICAL EDUCATION IN CONFERENCE.

HE progress that has been made during the past year by English County Councils in the application of their grants under the Local Taxation Act to purposes of technical education is attested by the map which accompanies the fourth Annual Report of the National Association for the Promotion of Technical and Secondary Education, and which we reproduce. It will be seen from this map that the counties which have determined to use the whole of the new fund for education form a large majority of the whole number both in England and Wales: and that London and Middlesex enjoy an unenviable, and we hope temporary, distinction, in having been the only counties to grab for the rates the whole of the money which might have been used to organize the secondary and technical education of their districts.

But while the map and the Report offer sufficient evidence of the good intentions of the County Councils. the solid progress already achieved is still more emphatically shown by the Conference of organizing secretaries which followed the annual meeting of the Association on the 3rd of this month. The very post of organizing secretary is the creation of the past few months. A year ago no county had dreamt of appointing an official to look after its education, and the Technical Instruction Act was only in operation in a few scattered centres Now nearly twenty counties and county boroughs have special educational departments, with paid organizing secretaries. We need hardly point out the wisdom of making such appointments, in view of the unwonted duties cast on County Councils by recent legislation. The task is one which needs all the ability which is available, and this ability is of a highly specialized character, not to be expected of the average County Councillor or Clerk of the Peace, who besides have not the time for the necessary detailed work of organization To leave the work to clerks would be to court failure, for the work to be attempted within the next few years must be largely tentative, and the direction of the experiments must be in the hands of men of knowledge, ideas, and resource, as well as of tact and judgment.

The selection of such men is not easy, and we are glad to find that the secretaries of the Technical Association are prepared to suggest candidates to County Councils which may be in need of them. The appointments made hitherto have been of two kinds: as temporary organizers, to nquire into claims and applications, to vait every district in the county, and to give any a detailed scheme as the result of such inquiry; and as permanent secretaries to the Technical Instruction Committees, charged with the work of carrying out the schemes and inspecting the instruction, either personally or through the employment of experts.

About two-thirds of the gentlemen who had been appointed up to the date of the Conference accepted the invitation to be present, the district represented being Lancashire, Cumberland, Surrey, Sussex, Derbyshire, Devonshire, Oxfordshire, Nottinghamshire, and Hampshire, besides a few county boroughs. The Conference was private and informal, its object being rather the interchange of views and the comparison of notes than the adoption of any formal resolution.

The subject chosen for consideration was the relation of the local taxation grant to secondary schools-the most difficult, as well as the most important, of the questions with which the organizer finds himself face to face when preparing a scheme. Since Matthew Arnold wrote, the disgraceful condition of secondary education in England has been a common-place; but how inefficient many of the schools are, and what tracts of country are entirely without even such facilities as they offer, is probably scarcely realized by any except those who have made a minute study of the educational wants of an average county. The country grammar-school, with small endowment and ill-paid and lethargic head master assisted by a worse paid and more inefficient usher, is all that stands for secondary education in many a market-town. Many are without even the semblance of a school above the elementary rank, and the mass of the inhabitants, it is to be feared, hardly feel the want of anything more Here and there an energetic master or governing body has succeeded in building up a good school in despite of local apathy and lack of funds, but the fee has to be pitched at a point which excludes wage-earners, and such schools are consequently "middle," not only in the character of their instruction, but also in the class by which they are attended. Meanwhile, the clever boy of the village national school, who might profit the nation by his brains and energy, is doomed, for lack of opportunity, to leave school at twelve for the hopeless rut of farm labour.

A country-side the general education of which is as here described is not a promising field for special technical instruction. A stupid set of uneducated farmers, and a carciely less stupid class of uneducated labourers, form hardly a good soil in which to plant lectures on agricultural chemistry or the natural history of insect pesss. And thus thoughful observers have been driven everywhere to the conclusion, no less in country than in town, that access to good secondary schools is an even more cryzing need at the present day than the specialized instruction to which, indeed, a sound general education is the necessary preliminary.

What, in short, is wanted, is that within reach of every inhabitant of every county should be a good secondary school, with fees such as may be reasonably expected to be paid by small farmers and tradesmen, and to which all some of artisans and labourers who can pass a reasonable examination before the age of twelve can have access by measo of scholarship.

The question before the Conference was the best means of promoting this object under the powers given by the Technical Instruction Acts. It will be remembered that the definition of technical Instruction in the Act of 1889 is sufficiently wide to cover most of the subjects taught in a secondary school, and it is therefore clear that aid can be given to such schools, provided that the County Council can be represented on the governing bodies, and that the schools are not conducted for private profit. As regards the erection of new schools, it is doubtful if the whole work of building could be undertaken, even if desired, by

the County Council, but there is nothing to hinder contributions from being made towards the cost of laboratory, fittings, and apparatus; while a maintenance grant could be given to defray the expense of the teaching of scientific and technical subjects. It was stated at the Conference that the Charity Commissioners had shown every dis-

nicked scholars from elementary to secondary, and from secondary to higher institutions, was unanimously agreed; and it was further considered that the scholarships to secondary schools should not merely defray the fees, but should provide something towards the cost of maintaining the boy while at school. The advantage of choosing the

schemes enabling the County Council to be duly represented on Severning bodies.

But the subject which chiefly occupied the attention of

the Conference was that of scholarships. That some NO. 1133, VOL. 44]

position to facilitate the work, by drafting amending scholars as young as possible, in order to give them the full advantage of secondary training, was also insisted

The question whether the selection of scholars, by examination or otherwise, should be undertaken by the scheme of scholarships should be devised to carry on County Council, or left to the governing bodies of the secondary schools, or to the discretion of the teachers of the elementary schools, elicited some difference of opinion; but on the whole the Conference favoured the plan of examination by a board appointed by the County Council, acting as far as possible in co-operation with the head masters of the secondary schools of the county. On one point all were agreed: viz. that there should be two examinations, or at least two standards-one for the country districts and the other for the towns-lest the whole of the scholarships should be monopolized by the most favoured districts. The opinion was also expressed that it might be sometimes desirable (as apparently would not be illegal under the Technical Instruction (Amendment) Act, 1801) to make scholarships tenable at certain efficient private profit schools, where no public schools are available, although such schools are debarred from receiving direct assistance. Such a course, however, would have to be adopted with the utmost caution.

Finally, the Conference considered the relations of the County Councils to the Technical Association, and a unanimous opinion was expressed in favour of a closer connection, while a suggestion was thrown out for the establishment of a quarterly journal registering the progress made in the various counties, a proposal which we are glad to hear is receiving the careful consideration of the Association.

Altogether, the discussion was felt to be of considerable value to those who have the practical work of organization in hand. We hope that such a Conference will be held annually, even if not more often, for in the novel work which lies before the County Councils points of difficulty will continually occur, on which consultation will be most useful. By the way, why should not the organizing secretaries form a permanent Association, on the model of the two Associations of Head Masters?

THE EVOLUTION OF ANIMALS. L'Évolution des Formes Animales, avant l'Apparition de l'Homme. By F. Priem 384 pages. Illustrated (Paris : Bailhère et Flls, 1891)

I N this addition to the series of volumes known as the "Bibliothèque Scientifique Contemporaine," we have a worthy companion to Prof. Gaudry's "Les Ancêtres de Nos Animaux," published three years ago. To some extent, indeed, the ground is covered by M. Gaudry's more ambitious "Les Enchaînements du Monde Animal," but since the latter is in three volumes, the present work ought to find numerous readers who might be repelled by the length of the other. Moreover, the work before us has the advantage of treating each group of animals throughout geological time in consecutive form, whereas in the "Enchaînements" the Palasozoic Invertebrates are described in one volume, and those of the Secondary period in another, while the Tertiary forms are not recorded at all Again, our author enters much more fully into the probable origin of one group from another than is the case in Gaudry's work. It is true, indeed, that in most cases these views are not original, but since they are generally taken from the highest authorities on the several groups, they will commend themselves the more strongly to students In most works on paleontology

NO. 1133, VOL. 44]

too little attention is, in our opinion, generally given to the evolution of the various groups of the Invertebrata from one another, and we can, therefore, give a hearty welcome to a volume like the present which is mainly devoted to this fascinating subject.

We need hardly say that Prof Priem is an out-and-out evolutionist: and we trust that we shall not disparage his work by observing that in some cases-apparently carried away by the very natural desire to make the most of his subject-he appears to have gone rather too far, stating as facts what are at best but probable hypotheses. For instance, we find it definitely stated on p 273 that the Stegocephalous (Labyrinthodont) Amphibians had a functional parietal eye, whereas there is, of course, no actual proof that this was the case

The work is rendered attractive by the large number of woodcuts with which it is illustrated. We regret. however, that in some cases-and more especially among the Vertebrates-the execution of these figures is by no means satisfactory. Moreover, in the chapters devoted to the Vertebrates (some of which are the weakest portions of the work) there are figures which are not only bad, but are utterly untrue to nature. Thus on p 266 the old figure of Coccosteus, with the maxillary bone doing duty for the mandible, once more reappears, while on p. 301 we have the reproduction of Goldfuss's erroneous restoration of Pterodactvius crasscrostres, which is unfortunately given as an illustration of the short-tailed genus Pterodactylus, whereas that particular species belongs to the long-tailed genus Scaphognathus.

We notice that in many instances M Priem gives his authority for his statements as to the phylogeny of particular groups, whereas in other cases such references are omitted. This is to be regretted, since it is often somewhat difficult to find out whether the author is promulgating his own views, or quoting those of others

The volume commences with an introductory chapter on paleontological evolution, in which the phylogeny of the horse, and the well-known passage of Paludina neumayri into P harness are instanced as the best examples we have of the derivation of one form from another. Following this chapter, we have the various groups of animals treated in detail, commencing from the lowest In the main the classification adopted is fairly well up to date, although we shall note some instances where the author departs from the more usual modern arrangements

For example, in treating of the classification of the Sponges on p 36, the author disregards Prof Sollas's separation of the Calcareous Sponges (Calcispongue) as a group of equal value with all the others (Plethospongia), so that we find the Soft, Horny, Flinty, and Calcareous Sponges ranked as equivalent groups Again, in the Coelenterates (or, as we prefer to call them, Zoophytes), the Palæozoic Corals are still classed under the primary divisions of Tabulata and Rugosa; the former group including such different forms as Favorites (belonging to the Zoanthana) and Heliolites, Halysites and Chatetes (usually referred to the Alcyonaria). Later on, however, pp. 62-64, the author recognizes Heliolites and its allies as the ancestors of the modern coral-like Alcyonarians, such as the Organ-pipe Coral (Tubipora), and we therefore fail to see his reasons for adopting the antiquated classification.

Some of the most interesting chapters in the volume are those devoted to the evolution of the Echinoderms, the author adopting Neumayr's view that the Palæozoic Blastoids, as well as Crinoids, Sea-Urchins, and Starfishes, are all separate branches springing from the Cystoids of the Palæozoic. The figures illustrating the gradual specialization of the Sea-urchins from the old Palæoechinoids, with their numerous rows of interambulacral plates, through the Triassic Trarechinus, and thence to the Neocomian Tetracidaris, with its two rows of anical interambulacrais splitting into four near its equator, and thence to the modern "regular" Urchins. strike us as particularly well selected. Equally instructive is the transition from the "regular" modern Urckins (Neoechinoids) to the "irregular" forms-at first with the retention of the masticating apparatus, and subsequently with its loss

Merely noticing that full justice is done to Neumayr's views regarding the phylogeny of the Brachiopods, we pass to the Mollusca, which we find treated in considerable detail and well illustrated. The author adopts the modern view of separating Dentalium as a distinct order (Scaphopods) from the Gastropods, and considers that both Pelecypods (Bivalves) and Scaphopods are derived from the latter. Nothing is said as to the origin of the Gastropods themselves, or, indeed, of the Cephalopodsprobably for the very sufficient reason that nothing definite is yet known. In regard to the mutual relations of the various groups of Cephalopods, the author comes to the conclusion that the Ammonites should form a distinct order, "Ammonoldea," to be placed between the Tetrabranchiates (Nautilus) and Dibranchiates (Cuttlefish) Since, however, he adopts the view that their shells were really external, and that they are probably descended from Nautiloids, there seems but little necessity for this third order. The gradual increasing complexity in the sutures as we pass from Goniatites to Ceratites, and from the latter to true Ammonites, is held sufficient to prove the descent of the latter from the former : while Goniatites are considered to be the direct offshoots from Nauriloids. which are themselves derived from straight forms like Orthoceras. It would require too much space to enter on the consideration of the relations of the various general of Ammonites to one another; but we may mention that the author fully adopts the modern views, such as the evolution of the keeled Amaltheus of the Jurassic from Ptychites of the Trias, and also that the uncoiled forms (Hamstes, Scaphstes, &c.) have had several distinct points of origin from true Ammonites And here we may take the opportunity of mentioning that the terms Ægoceras and Hatloceras applied to genera of Ammonites, are preoccupied by two well-known genera of Mammals, and therefore require changing. In regard to the Dibranchiate Cephalopods, it is considered that Belemnites have been derived from forms allied to Goniatites, and have themselves given origin to the modern Cuttle-fish. If this be the true phylogeny of the Cephalopods, it indicates a gradual increase in the complexity of the shell of the Tetrabranchiates, till it attained its maximum in the jurassic and Cretaceous. Then the total disappearance

NO. 1133, VOL. 44]

of all the external-shelled forms with the exception of the Nautius, while at the same time the Dibranchiates were gradually tending to develop less and less complex internal shells, till these culminated in the simple "pens" and "bones" of the modern cuttles and squids.

Coming to that portion of the work devoted to the Vertebrates, we find, as a irready mentioned, that the author has been in some places less successful than in the earlier chapters. We have already alluded to the misleading nature of one of the figures in the chapter on fishes, and we have to add that several of the few others with which that chapter is illustrated are highly unsatisfactory. It is probable, indeed, that the author had no opportunity of seeing the second volume of the "British Museum Catalogue of Fossi Fishes" before passing his proofs, as otherwise he would doubtless have modified

In his remarks on the difficulty of distinguishing between Dipnoid and Ganoid fishes (p. 265), the author seems to be totally unaware of the difference between the "autostylic" skulls of the former and the "hyostylic" of the latter, and when, on p 267, he states that the Dipnoids are a lateral branch of the Crossopterygian Ganoids. he is directly at issue with the writer of the Museum Catalogue, who states (p xx) that, "concerning the evolution of the Dipnoi, palæontology as yet affords no information " Again, although Prof Cope's observations as to the primitive structure of Pteraspis and its allies are referred to, we doubt whether the suggestion that the opening on the dorsal side of the head-shield corresponds to the aperture of a parietal eye will commend itself to the students of ichthyology. The chapter on the Batrachians is all too short, and, bearing in mind their resemblance to the Dipnoids in the autostylic structure of the skull, it is scarcely safe to make the statement (p. 282) that they are derived directly from Ganoids.

From his treatment of reptiles we fear that the author has but a very faint conception of the nature of a Theriodont or a Dicynodont, or else he would surely have made more of their affinity to the Batrachians on the one hand, and to Mammals on the other, while he would have also omitted any reference to the purely adaptive resemblance existing between the skull of Udenodon and that of a turtle. M Priem might also have informed his readers that Dicynodonts are not confined to Africa. On the other hand, we are pleased to see that M. Priem rejects the heresy propounded by some of his countrymen, that Ichthyosaurs were derived primitively from marine reptiles, in favour of the more rational view of their near relationship to the Rhynchocephalians. In stating that the Plesiosaurs are likewise related to the Rhynchocephalians, the author is in accord with modern views, although he should also have referred to the many indications of affinity presented by these reptiles to the Chelonians. When, however, it is stated, on pp. 295, 296, that the latter were probably derived from the toothless Dicynodonts (Udenodon), the author at once proclaims his ignorance of some of the leading features of reptilian osteology. The statement on p. 297, that the gigantic Siwalik tortoise had a shell measuring four metres in length, leads us to wonder when this fiction will finally disappear from text-books. The author's treatment of the Pterodactyles and Dinosaurs calls for no separate mention, although we are led to wonder why the Crocodiles are so widely separated from these groups.

The whole chapter on birds is decidedly feeble; and we must certainly take exception to the statement that Hesperorms and Ichthyorms respectively connect Archaopleryz with the Ratitæ and Carinatæ.

Turning to the last chapters, on the Mammals, we find the author adopting the view that the Monotremes have had an origin totally separate from the other two subclasses. We then have a notice of the Secondary Mammals, in which we observe a lamentable lack of attention to recent work on their affinities, and also to the synonymy of the various genera. We also notice that the Jurassic Plagiaulax and its allies are still referred to the Diprotodont Marsupials (p. 327), so that on these points the author's evolutionary views are totally out of date Following the Marsumals, we have a very fair, although brief, account of the most recent conclusions on Mammalian phylogeny, which needs but few remarks notice, however, that the author adopts M. Boule's views as to the dual origin of the Canada, according to which the Foxes (Alopecoids) are considered to have originated from Cynodictis, while the Wolves, Jackals, and Dogs (Thoulds) trace their descent to Amphicyon To ourselves, indeed, it has always appeared difficult to understand how these two groups of Canada have become so much alike if they had this dual origin, and this difficulty is increased by the author's statement that those Thooids known as Cyon differ from the other members of that group in having originated from Cynodictis,

On p. 343 the author makes a slip in stating that the Hydracoidea are now represented only by a single genus. while later on he appears to be uncertain whether the Siwalik beds should be regarded as Upper Miocene (pp. 349, 350) or Upper Pliocene (p. 366). Again, we notice on p. 353 some want of acquaintance with the recent literature relating to the ancestry of the horse, Oroluppus being identified with Pholophus, whereas the latter is really the same as Hyracotherium, while the former is identical with Pachynolophus. We are in full accord with the author when he states, on p 361, that Chalico-therium (with which the supposed Edentate Macrothersum is now known to be identical) is an aberrant Ungulate, although we must be permitted to differ from him when he adds that it shows signs of affinity with the Edentates.

We must likewise take exception to the statement, on p. 370, that the Indian Nilgai is in any sense the progenitor of the Oxen, while the view expressed on the same page, that the Buffaloes, Bisons, and true Oxen have severally originated from three distinct groups of Antelopes, can be only regarded as another instance of the author's partiality for multiple phylogenies. Although M. Priem is careful not to commit himself to the view that the Cetaceans have been derived from the extinct Enaliosaurian reptiles, yet the prominence which he gives to the statement of that view may be taken as a sign that he has not thoroughly purged himself from that

Finally, although we have felt bound to call attention to a certain amount of imperfection in the later chapters, work before us to those readers who are desirous of obtaining in a compact form a summary of the evidence afforded by palæontology of the progressive evolution of animal forms R. LYDEKKER.

METALLURGY.

Lecons sur les Métaux Par Prof. Alfred Ditte (Paris Dunod, 1891)

Tratté pratique de Chimie Métallurgique. Par le Baron Hans Juptner von Jonstorff Translated from the German by M. Ernest Vlasto. (Paris: Gauthier-Villars, 1891)

THESE two volumes, recently published, are both of unusual interest The first, by Prof Ditte, who is well known to English readers by his "Exposé de quelques Propriétés générales des Corps," may be said to mark a new departure in teaching the chemistry of metals. He points out that the principles of thermochemistry do not merely enable reactions to be explained, but to be predicted, and, on the other hand, when two sets of reactions are simultaneously possible, the laws of dissociation render it possible to rigorously define the conditions of equilibrium which are established in the chemical "systems" under consideration. It is often possible, with the guidance afforded by these laws, to say, in the absence of direct experiment, why one reaction is impossible and another certain to occur, or why a certain reaction begins without difficulty, and is arrested at a definite stage; or why a reaction which takes place readily under certain conditions cannot be effected under others that do not appear to differ greatly from those which were favourable to it. As a pupil of Deville, the author might have been expected to develop, in a treatise such as this, the teaching of his great master, and he has admirably performed his task. The classification of the work is excellent, the metals being first considered collectively, and then in detail with numerous tables of the data and constants which are so frequently required by metallurgists.

The work begins with a very clear account of Berthelot's labours in mécanique chimique, special care being devoted to the description of the calorimetric investigations, and to the appliances adopted in these important researches.

It appears to be a great advance for us in this country to read a chemical treatise in which the thermal values of the equations are stated in calories, side by side with the formulæ, As the book is too long to review in detail, it may be well to indicate the nature of one section only, as showing the author's care and thoroughness in the selection and arrangement of the materials. Take, for instance, the few pages devoted to carbides. The author points out that carbon in uniting with metals sometimes gives rise to the formation of true compounds, and at others to solutions of carbon in the metal. He then describes the orange-vellow product obtained by the action of carbon on metallic copper, and passes to the association of carbon with nickel, which does not confer upon nickel the property of being hardened by rapid cooling. The definite carbides of manganese, as well as the indefinite associations of yet, as a whole, we can conscientiously recommend the carbon with iron and manganese, receive due attention, and the author proceeds to deal with the carbides of iron, and finally with the well-defined carbides of mobium and tantalium, which have respectively the formulæ

Nb₂C, and Ta₂C₂
A terse description is then given of the work of Troost
and Hautefeuille on the heat of formation of carbides of
iron and manganese, which led to the conclusion that the
union of carbon and iron is attended with absorption of
heat while in the case of the union of carbon and man

bellow the Crown and row is attenued with absorption of the case of the union of carbon and maniganese heat is evolved, the evidence leading to the belief that Mhg.C is a true compound possessing considerable stability. The action of heat on carbodes is then dealt with, and a brief, but sufficient, reference is made to Forquignon's work on the action at a high temperature of hydrogen on cast-iron. The section concludes with a description of the modes of preparing carbodes, and with a sketch of the formation and properties of the nitrocarbides, more especially those of niobium and titanium.

The sections of the work devoted to the consideration of tellurides, areendees, and antimonides, are equally good. With regard to individual metals, in the portions of the work as yet published, only potassum, rubidium, cesium, ammonium, thallium, sodium, lithium and the metals of the alkaline earths, barium, strontium, and calcium are dealt with, but sufficient evidence of the ments of the book has been given in this brief review to show that the rest of it will be gladly welcomed, for Prof. Ditte has earned his place among the great metallurgists of France.

We should be grateful for curves indicating the effect of definite elements on the physical constants of metals.

Baron Jonstorff's book is of an entirely different character, though it in one, in its way, less excellent or useful. He says that it issues from an ironworks, and is addressed to practical metallurgists. Its aim is, however, somewhat different from that of most treatises on analytical chemistry, the author's intention being not merely to grade the chemist in his analytical methods; but to enable a blast-furnace manager or an iron-master to realize what kind of services the laboratory can render, what questions relating to the routine of work the analyst can solve, and, above all, in what way the questions should be and.

The author deals with the more important special methods of analysis, and of assaying iron and steel, and he gives due attention to the examination of refractory materials—slags, fuel, and gaseous products—and his method is singularly clear and precise. An appendix gives tabular statements which will be useful in daily work.

The book, as a whole, shows incidentally the great difference between the work-aboratory of the present day and that of twenty years ago. There is still much ironworks has, in many cases, cased to be little better than a shed, erected, say, behind the boiler-house, with an analyst and a few boys as the scentific staff.

Those who have visited the author in his beautifully stuated Syrian works, and have seen his manipulation, as the reviewer has, will appreciate the excellence of his labours, and will be glad that a good translation into French will make their results more generally known.

W. C. ROBERTS-AUSTEN.

NO. 1133, VOL. 44]

BACTERIA AND THEIR PRODUCTS.

Bacteria and their Products. By Sims Woodhead, M.D.
Published in the "Contemporary Science Series."
(London, Walter Scott, 1801)

SCARCELY a year passes in England, France, or in Germany, without the publication of one or more treatises on the fascinating subject of bacteriology. Many of the more recent of these works have been written for the general reader rather than for the student, and have shown a considerable want of accuracy and lucidity, a circumstance which can only be accounted for by the fact that accomplished bacteriologists have not been their authors.

We have now before us "Bacteria and their Producta," a work which we might infer from a glance at the cover, and general arrangement, to be certainly intended for the general reader. This wew is strengthened by the several object-lessons and homely similes scattered throughout the text, with the fitness of which we totally disagree; untess, for example, the extraordinary comparison of a nodule of Actinomyces with two datay heads placed base to base, "the sterile flowers in the centre" then corresponding to the club-shaped rays. The comparison is bad, but the botany is worse. Then there is the not very abstruse mathematical problem on p 24, and the guide-like description of the Pasteur Institute, all intended, we must conclude, for the general reader rather than for the student.

On the other hand, there is a very large collection of facts, much information about fermentation and chemistry (although the interesting and oft-quoted experients of Raulin are omitted), numerous references, and a very plentiful supply of formule, the whole requiring, in order to understand and appreciate them, a reader equipped with a thorough knowledge of the sciences bearing on the subject.

Putting this question aside, however, we candidly confess that we do not admire the style or arrangement of the book. There is a conspicuous want of lucidity, and of that accuracy of observation which one would have expected of the author For instance, "What are Bacteria?" is the question propounded in chapter ii. : but the answer to this key-stone question is left in much doubt, as the description of the protoplasm, cell membrane, mode of division and reproduction of the "specks," is exceedingly confused. We should not choose Gram's method to demonstrate the capsules of Actinomyces, nor, indeed, any other capsules, and we have reason to doubt, after the beautiful monograph on Cladothrix by Billet, that the brown colour of that organism is due to iron Again, what does the author mean when, speaking of cilia, he says, they "appear to develop only in those organisms that have special affinity for oxygen, for, as soon as the cultated forms reach the surface of a fluid. they lose their cilia or they become much less active." &c.? Tables of classification are heaped in with scarcely any attempt to sift and reduce them to a form compatible with the scope of the book. Is this done because, as the author says (p. 47), " to the pathologist, however, these classifications are of comparatively little value"? We maintain that for a work of this kind the author has no right to take a one-sided view, and that to the science of bacteriology the study of morphology is as important as any other side of the subject.

Turning to the description of actinomycosis and anthrax, we are surprised to find McFadvean taken as the guide in the former. Why is not the author his own guide? Or why does he not, at least, use the recent results of Boström? Then in "anthrax" it is stated "that at the point of inoculation in animals there is usually no evidence at all that it has been the point of entrance of the bacilli " This is scarcely compatible with a thorough knowledge of this familiar organism

Again, in the opening chapter, a number of bacteriologists' names are mentioned. We think the author hardly does justice to those of our own country, for amongst the four names placed by the author in honourable association with the great name of Sir Joseph Lister, neither Lankester, nor Tyndall, nor Lawes and Gilbert, nor Wooldridge, nor Lingard, finds a place And yet not only are these amongst our highest authorities, but the observations of Lankester and the experiments of Wooldridge constitute cardinal points in the history of bacteriology.

Lastly, the question of illustrations is a difficult one There are very many photographic processes to choose from, and considering that there are only 20 illustrations. the author might have employed collotypes (compare Frankel's atlas) or copper blocks, or, having used zinc blocks, should have had them printed on separate sheets, for it ought to be more generally known that it is of no use expecting a good impression from blocks of this description when printed on ordinary paper and in the text

OUR BOOK SHELF

Our Country's Flowers By W. J Gordon. (London Day and Son, 1891)

THIS volume is intended to aid beginners to ascertain the botanical name of any British wild flower or fern with which they may meet. After a list of local English plantnames, the serious work of the book begins with an explanation of how plants are classified, interwoven with which are a sufficient number of the terms used in describing plants to make the book "not too technical, but just technical enough" for the reader who desires to have a "nodding acquaintance" with the wild flowers of his own country This is given first in a chatty style, and then repeated in a convenent tabular form Next, the essential characters of the natural orders are given, after which the buttercup order, or Ranunculacere, is treated of at some length as a pattern of how identifications can be made. This is followed by a glossary of botanical terms, in some of which, in attempting a condensed and popular style, the writer has somewhat distorted the meaning. " Cambium " is erroneously described as a layer of mucilage, instead of a tissue. The characters of the natural orders are again stated, this time in alphabetical sequence, followed by a chapter on the genera, each of which is accompanied by a woodcut, intended to show its diagnostic character, but it is doubtful whether (at least in some of the orders) this is accomplished, as is also the case with some of the specific diagnoses with which the volume closes.

specific diagnoses with which the volume clovers.

In the 33 coloured plates 509 species are depicted. This crowding is unsatisfactory, and tends to obscure what might otherwise be very useful. The figure on plate 23, numbered 388, may possibly be intended for 508, the slinging-nettie, or 1t may be some abnormal

state of the inflorescence of a grape-vine. Centranthus ruber (204) and Plantago lanceolata (346) are also wonderful specimens of those plants The ariist, apparently, is amongst those who do not regard colour (unless it be the quantity thereof) as of value in discriminating species. The volume will, nevertheless, be a pleasant and useful companion to many during a country holiday, and, with the author, we hope will lead on to deeper study

A Summary of the Darwinian Theory of the Origin of Species By Francis P Pascoe, F.L S, &c. (London. Taylor and Francis, 1801)

It is difficult to understand why the author of this pamphlet should think it worth while to remind his readers periodically that he is an opponent of Darwinism Some space was recently devoted in these columns to the consideration of a book on the same subject by Mr. Pascoe, and the present production is nothing more than an abstract of this work, delivered in the form of an address to the Western Microscopical Club We have no new facts nor arguments, there is the same lamentable display of misconception, and the author has simply strung together some sixteen pages of excerpts from the writings of Darwin and others, without any attempt at connected reasoning either for or against the Darwinian theory. The author's position is practically this; here is the whole animal kingdom, consisting of about 600,000 species, you must explain every detail of specific structure, down to the most insignificant, by the theory of natural selection, if you cannot do this, the theory is The whole of Mr. Pascoe's writings in conuntenable nection with Darwinism amount to this, and nothing more: be has reiterated this statement, if not literally, at any rate in spirit, on every available opportunity for the last twenty years. The present pamphlet will, let us hope, for the sake of the author's reputation, be the last declaration to the same effect, for there is surely nothing gained either by Darwinism or anti-Darwinism by squandering the systematic powers which he is known to possess in picking out scraps of sentences from the "Origin of Species," &c., and publishing these things "of shreds and patches" under grandiloquent and misleading titles

The Business of Travel. a Fifty Years' Record of Progress. By W Fraser Rae. (London: Thomas Cook and Son, 1891)

THIS year the well-known firm of Thomas Cook and Son celebrate their fiftieth anniversary, and Mr. Fraser Rae has taken the trouble to write the present work in order to mark the occasion. The firm, it seems, had very small beginnings. Its history may be said to date from the day when, in 1841, Mr. Thomas Cook, walking along a country road, suddenly reflected that a certain temperance meeting at Loughborough would probably be a ance meeting at Lougnorough would productly ex-brilliant success if a special excursion train could be run between that place and Leicester Apparently, no such thing as a special excursion train had ever before been heard of. The idea was carried out, and attracted so much attention that Mr. Cook-who was at that time a wood-turner-was often asked afterwards for advice in wood-turner—was onen aseen aiterwards to radice in the organizing of railway excursions; and by and by he devoted himself wholly to the task of developing "the business of travel." His son has been for many years the sole managing partner, but to the elder Mr. Cook belongs the credit of having conceived the system with which his name is now associated. To what vast proportions the system has grown everyone knows; but there are probably few who know much about the various stages through which it has advanced to its present position. Mr. Fraser Rae tells the story clearly and effectively, and most readers, when they have finished his narrative, will be disposed to agree with him in thinking

that the jubilee of a firm which has played so prominent a part is an event of interest in the social history of the a part is an event of interest in the social instory of the nineteenth century. Messrs. Cook, by their energy and enthusiasm, have given a powerful stimulus to the popular love of travel; and they may fairly claim that their establishment ranks to some extent among the mfluences which are tending to break down international prejudices.

IETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions ex-peried by his correspondent: Nather can he underlake to return, or to correspond with the vortiers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of annymous communications!

The Albert University.

I DESIRE to associate myself with Prof. Carey Foster and, to agent extent, with Prof. Ray Lankester in the sistements of the professional professional professional professional Present circumstances force me to do so as briefly as possible; but I should be the less satisfied to keep attogether silent be-cause I had something to do with the drafting of the "Aibert"

charter in 1887. charter in 1887.

For my part, that draft was never regarded as an effective solution of the problem of a University for London I thought of it only as a handy weapon for forcing the appointment of a Royal Commission, and for shaking the London University Senate out of its happiness in the steady increase of untaught candidates for degrees.

candidates for degrees.

A Commission was extorted; and it had the impartuality, at least, of generate R in tuning was short and hurred, yet it by the London Colleges, during suity years, to condemn the inflicency and self-sufficiency of the London University. That understand the london University is a comparable to the london University. That was not to be a long to the london University. That was not to be a long to the london University in the london University is not long to the london University and the london University is considered to the london University of the london University Sensite We know what followed. The London University Sensite was the london University Sensite when the london University Sensite was the london University Sensite when the london University Sensite was the london University Sensite when the london University Sensite was the london University of the lo

We know what followed. The London University Senate was allow, very allow, to more at all towards meeting the London Colleges. But at list it woke up, and then after a mee began real accommodation seemed to have been sittained between the Councils of the Colleges on the one hand and the University Senate on the other. Even when the Senate threater, yielding give these also a direct representation (in the Leeth of the Commission's instruction and without warming to the London Colleges), I was one of those who here were still willing to try the contraction of the Colleges of the Colleg

It looks now as if the "Albert University" were straight way to be upon us instead I will not inquire into the agencies that have brought this result into such near view Nor will I in your columns follow up my present and my late colleague's arguments against the prospective creation with others that seem to me of serious import. But I may be allowed to endorse emphatically what Prof. Lankester has said as to the

to endorse emphatically what Prof. Lankester has said as to the sheenee of sanction by the professoral body here to the "Albert" draft charter. And nothing could be more to the point than Prof. Tostler's observation that the "Albert" scheme has never been unbuilted to a meeting of the Governor. Prof. Lankester vi clearly right in contending that the whole question should now have been, or should still be, referred back the Commission. I must, however, as a Socr, remark spon has assumption that the Northern Universities are professorably the machineous lay influence of more graduates. The fact is, that, ever nace 1860, graduates, in "Greenel Council" and also by direct representation in the 'University Court," have not been without voice or influence, while, by the later reforms and been without voice or influence, while, by the later reforms of the professorable powers of general ansangement are largely diminished or even (as respects finance, &c.) NO. 11.23. VOI. Add

abolished. There were more reasons than evidently Prof. Lankester knows of for curtailing the old professoral supremsey in a locatiand. But it does not follow that in England, and more especially in London, there should not be a much franker recognition of professoral (that is, expert) knowledge of educational ends and means than appears in the "Albert" draft. G. CROOM ROBERTSON. charter.

University College, London

P.S.—Since these remarks were put in print, a decision of the Pray Council has been announced in favour of an "Albert" (or "Metropolitan") University They lose, therefore, most of whatever interest they may have had; but they may still appear, to far as I am concreted, if the Editor pleases. I regart the decision, and think the promoters of it may yet have reason to with that their action had been less harract. At the same time, one may acknowledge the remarkable energy and fertility of resource with which the enterprise has been conducted to its thus far successful issue.—G. C. R.

It I may be allowed another word on this subject, I should like to say that, having been all along a keen advocate of the establishing of a strong professorial University in London, not necessarily in alaysh imitation of the German system (of which I happen to know something), but combining the main features of its professoriate (of which I think I abnowd my appreciation in a paper read at Bath in 1888, before Section B of the British in a paper read at Bath in 1888, before Section B of the British Association) with the essential elements of the present University of London, and believing that the draft charter of the Senate, which was presented to Convocation, contained in it the poten-

tighttes, out of which (with the exercise of a little common-sens tialities, out of which (with the exercise of a little common-sense to soften down such asperties as might cause friction in its initiatory working, together with a little patience to allow for the time necessary in all evolutionary changes) a strong professorial University could be developed, I woted for the Senate's scheme, and still think the adverse vote of Convocation ti greatest disaster that has befallen the University in the half-century of its existence

Of all the bitter things said by Prof. Lankester in his former

Of all the bitter things said by Prol. Lankester in his former letter, nothing was more to the point than his sarcastic challenge to the existing University to reform itself, if it can, with the "dead weight of graduates tied round its neck, and called Convocation." But must an institution, which has admittedly Convecation." But must an institution, which has admittedly done so much food, he swamped because of the accident of a food so much good, he swamped because of the accident of a stone from its neck? If anything can exceed one's admiration for Froil Lankesser's candoor in penning the letter, which appears in NATUEE this week! (July p. 922), it is the speak of the penning the letter, which appears in NATUEE this week! (July p. 922), it is likely appears in NATUEE this week! (July p. 922), it is likely appears in NATUEE this week! (July p. 922), it is likely appears in NATUEE this week! (July p. 922), it is likely appeared to the penning Commission, and that the Commissioners will give such advice to the "powers that be," that the shortsighted decision of to the "powers that be," that the shortughted decision of Convocation may be overruled, a For I ankeater has suggested twice over, and that (to use the words poken to me, the case acidemical expension so one could challenge) "the Government will take up the matter, and pass an Act doing what monume, ansated observations of the convocation of the convoca

Prof. Karl Pearson's idea of the "fusion" of the two Colleges (see NATURS, June 4, p. 103), as dutinit from "federation," is splendld in theory; but will it work? Can the fluxing material be found, which shall make the rion and the clay inter-fuse without either Gower Street or Somernet House, or both, sacrificing those traditions which are the strongest element in that individuality which each values to highly and both seems to anxious to conserve?

Wellington College, July 10.

Name for Resonance,

Al-Hottott inadvisuals as rule to correct errors in a report for which one in not responsible, there is one little missake on no 238 thus week, which uncorrected, may lead to the extinction of a useful suggestion.

In discussing the subject of "electric resonance" recently at Cambridge, I found that the term conveyed no correct meaning.

to the untechnically instructed. Its natural meaning implies echo or reverberation, and has a definite relation to sound Now, although a sort of reverberation or repetition in part of the effect intended to be denoted by the phrase resonance, yet the most seasonial feature of that phenomenon, and the one most is be emphasized in the recent extensions of the term, viz the accord of frequency or similar tuning between two vibrators, is not connoted at all. Hence, even in acoustics the term is hardly satisfactory, while its extension to other departments of physics may be misleading.

may or misseasing.

It was suggested, however, by Dr. Arthur Myers, that the existing word everower has almost exactly the right connotation, and has no special limitation to sound; while the derivatives syntony, syntonic, and syntonise may readily become English

systemy, systemic, and systemic may readily occure English without excling repulsion. The adjective "symphonic," suggested by the reporter of the Physical Society, does not strike me as 20 good, because it specially refers to sound again, and because the word "sym-phony" has already another definite meaning July 10. OLIVER L. LODGE.

Force and Determinism.

I no not think there are many non physicists who will attempt to gainsay the fact that, under physical constraint, the direction of motion may be determined without affecting the quantity of motion of the determined without affecting the quantity of This is seen when the earth and sun revolve around their common centre of gravity, or when I towit my stock around my finger and thumb, the earth and sun in the one case, and the ferrile and knot of my stick in the other case, being bound into one system physically. But I do think that an able and clear headed physical like Dr Oliver Lodge would be doing a clear beaded physicant like Dr Oliver Lodge would be doing a great service to non-physicate if he would, in your widely-nical language, the difficulties which trouble some of them, aiding them, for example, to comprehend the exact force of the words expenditure of energy, and helping them to see that in all known ease of change of direction of motion such change is all known eases of change of direction of motion such change is effected under physical constraint. It is when they are told by a certain class of metaphysicans, who quote, or misquote, physica in support of their assumptions, that physical motion is controlled by will-power or volition, always acting at right angles to direction of motion, and therefore leaving the amount of energy unchanged, it is Alen, I say, that they begin to grow restive, and to demand definite and vertifiable evidence that reture, and to demand definite and vertilative evidence that such metaphysical constraints it faire Sir John Henschel) a necessary or philosophical conception, and that it is impossible to explain the phonomena without having recourse to ir If Dr. Lodge would consent to help non-physicatis in this way, and would indicate what are the "important psychological consequences" to which he alludes, he would he doing some of us a good turn. C. L. LOVD MOKAM a good turn. University College, Bristol

As Prof. Lodge says he is glad to see that his statement, AS 1701. Longe says ne is guad to see that ms naturemen, "although expenditure of neargy in needed to increase the speed of matter none is required to alter its direction," called in ques-tion, and as he has so kindly answered one letter on the subject, may I ask him to criticise the following remarks?

The theory of kinematics is based on certain geometrical con-

cepts, which may be summed up in the term space, and on the concept of time The laws of motion, together with the assertion that mass is not a function of space or time, may logically be regarded as implicitly defining mass and force. Energy may similarly be defined, in terms of these kinematic concepts, as The For I think the progress of science is tending to show that the term "potential energy" is only a cloak to cover our ignorance of the kinetic energies which for the moment have gnorance or new nieut energies which for the moment has considered the statement quoted is logically only a truism, deduced from the definitions of interms, and is therefore indisputable in all mechanical theorems. But if it is to be applied outside the sphere of pure mechanics, the moral will be in the application of it—that as, it will be necessary to examine, before applying it to any new subject-matter, whether the definitions from which it was deduced apply to that subject-matter or not,

to tank subject-matter or not.

For example, by the third law of motion, mechanical force only acts between two masses, the momenta generated in them being equal and opposite. If, therefore, psychic force is to

come under the definition of mechanical force, it can only act between two particles. And, therefore, if psychic force is to do no work, by reason of its always acting in a direction normal to the path of a particle, it can only act between two particles whose paths happen to have a common normal-an occurrence which must be infinitely rare 12 Barkston Manssons, South Kensington, July 4.

Magnetic Anomalies,

THE discovery of very strong magnetic anomalies between Charkov and Kursk in Russia, to which A de Tillo has lately referred in the Comptes rendus and in NATURE, raises the question whether the values there observed are strictly local or extend over a relatively wide area. Thus, it would be of or extend over a relatively wide area. Ints, it would be of great interest to know if, on moving, say, some metres away from a station, the declination and inclination hold the same value. If not, there is clearly some cause which acts at a short distance, but if constancy is observed, a great step would be taken towards the settlement of the question as to the existence of strong variations common to a wide area

or strong variations common to a wice area. When magnetic anomalies are observed, the first thing to be done is to ascertain whether the values found in a given locality have a definite meaning—that is, whether they do not change for slight displacements, otherwise, the determination of the magnetic elements has no meaning, as it is impossible to refer magnetic elements has no meaning, as it is impossible to refer them to geographical co ordinates

The overlooking of this precaution has often led to serious istakes.

Alfonso Sella, mistakes. Biella, July 4.

Physical Religion.

As a constant reader of NATURE from its commencement, and the possessor of its forty three and a half volumes, I venture (after reading the review of "I'hysical Religion" in this week's number) to ask if it is intended to develop it into a theological journal Because, however smart it may be to abolish Abraham without "even taking the trouble to discuss" him, or to dispose of Lux Munds in a contemptuous sentence, it is hardly in

of Lux Minute in a contemptuous sentence, it is narray in accordance with scientific methods. It is curious that many "Agnostics," though by their own showing (if they would talk Latin instead of Greek) they are Lewisimises at best, should be so certainly sure of everything. when a little reflection and modesty might satisfy them that as "Know nothings" (in plain English) they have no more right to

deny than to assert

The standing motto of your title might be improved by the addition of "Ne supra crepidam sutor" Hompstead Heath, July 11 B WOODD SMITH

SOME APPLICATIONS OF PHOTOGRAPHY!

ONE of the subjects to which I propose to invite your attention this evening is the application of instantaneous photography to the illustration of certain mechanical phenomena which pass so quickly as to elude ordinary means of observation The expression "instantaneous photography" is perhaps not quite a defensible one, because no photography can be really instantaneous
—some time must always be occupied One of the simplest and most commonly used methods of obtaining very short exposures is by the use of movable shutters, for which purpose many ingenious mechanical devices have been invented. About two years ago we had a lecture from Prof. Muybridge, in which he showed us the application of this method—and a remarkably interesting application it was-to the examination of the various positions assumed by a horse in his several gaits Other means, however, may be employed to the same end, and one of them depends upon the production of an instantaneous light. It will obviously come to the same thing whether the light to which we expose the plates be instantaneous, or whether by a mechanical device we allow the plate to be submitted to a continuous light for

' Friday Evening Discourse, delivered at the Royal Institution of Gree Britain, on February 6, 1891, by Lord Rayleigh, FRS, Professor of Natural Philosophy, RI

only a very short time. A good deal of use has been made in this way of what is known as the magnesium flash light. A cloud of magnessum powder is ignited, and blazes up quickly with a bright light of very short duration. Now I want to compare that mode of illumination with another, in order to be able to judge of the relative degree of instantaneity, if 1 may use such an expression, We will illumine for a short time a revolving disk, composed of black and white sectors, and the result will depend upon how quick the motion is as compared with the duration of the light. If the light could be truly instantaneous, it would of necessity show the disk apparently stationary I believe that the duration of this light is variously estimated at from one-tenth to one-fiftieth of a second; and as the arrangement that I have here is one of the slowest, we may assume that the time occupied will be about a tenth of a second I will say the words one, two, three, and at the word three Mr Gordon will project the powder into the flame of a spirit lamp, and the flash will be produced. Please give your attention to the disk, for the question is whether the present uniform grey will be displaced by a perception of the individual black and white sectors [Experiment] You see the flash was not instantaneous enough to resolve the grey into its components.

I want now to contrast with that mode of illumination one obtained by means of an electric spark. We have here an arrangement by which we can charge Leyden sufficient, a spark will pass inside a lantern, and the light proceeding from it will be condensed and throw upon the same revolving disk as before. The test will be very much more severe; but, severe as it is, it think we shall find that the electric flash will bear it. The teeth on the outside of the disk are very numerous, and we will make them revolve as fast as we can, but we shall find that the electric flash will bear it. The teeth on the statemant of the statemant of

and the property of the property of the park because with a great a limit to the duration of the spark, because with a little care we could determine how fast the teeth are tragariant and the property of time. For this purpose it would not be safe to calculate from the multiplying gear on the assumption of no ship. A better way would be to direct a current of air upon the teeth themselves, and make them we have to a musical teeth themselves, and make them we have to a musical the disk under the spark we might safely say, I think, that the duration of the light is less than a tenth of the time occupied by a single tooth in passing. But the spark is in reality much more instantaneous than can be proved by the means at present at our command. In order to determine its direction, it would be necessary to have redetermine the duration, it would be necessary to have redetermine to direction, the control of the matter to-night.

Experiments of this kind were made some twenty years ago by Prof. Rood, of New York, both on the duratique of the discharge of a Leyden jar, and also on that of lightning. Frof. Rood found that the result depended somewhat upon the circumstances of the case, the discharge that of a larger one. He proved that in certain cases the duration of the principal part of the light was as low as one twenty-five-millionib part of a second of time. That is a statement which probably conveys very little of its as the statement which probably conveys very little of its as most twenty-five-millionib part of a second of time. That is a statement which probably conveys very little of its as most twenty-five-millionib part of a second of survey and mights. I wenty five million seconds is nearly a year, see perment is about the same fraction of one second that one second is of a year. In many other cases the duration was somewhat greater; but in all his experiments

it was well under the one-millionth part of a second, In certain cases you may have mulpile sparks. I do not refer to the outlining discharges of which Prof. Lodge grew us so interesting an account last year; Prof. Road's multiple discharge was not of that character. It consisted of several detached overflows of his Leyden jar when charged by the Rhumkorff coil One number mentioned for the total duration was one six-thousandth part of a second; but the individual discharges had the decree of instantanenty of which I have stocker.

It is not a difficult matter to adapt the electrical spark to instantaneous photography. We will put the lantern into its proper position, excite the electric sparks within it, causing them to be condensed by the condenser of the lantern on to the photographic lens. We will then put the object in front of the lantern-condenser, remove the cap from the lens, expose the plate to the spark when it comes, and thus obtain an instantaneous view of whatever comes, and thus obtain an instruction view of whatever may be going on I propose to go through the opera-tion of taking such a photograph presently. I will not attempt any of the more difficult things of which I shall speak, but will take a comparatively easy subject—a stream of bubbles of gas passing up through a liquid. In order that you may see what this looks like when observed in the ordinary way, we have arranged it here for projection upon the screen [Experiment.] issues from the nozzle, and comes up in a stream, but so fast that you cannot fairly see the bubbles. If, however, we take an instantaneous picture, we shall find that the stream is decomposed into its constituent parts arrange the trough of liquid in front of the lantern which arrange the trough of indud in front of the lantern which contains the spark-making apparatus—[Experiment]— and we will expose a plate, though I hardly expect a good result in a lecture A photographer's lamp provides some yellow light to enable us to see when other light is excluded. There goes the spark; the plate is exposed, and the thing is done We will develop the plate, and see what it is good for ; and if it turns out fit to show. we will have it on the screen within the hour

In the meantime, we will project on the screen some sides taken in the same way and with the same subject. [Photograph shown.] That is an instantaneous photograph of a stream of bubbles You see that the bubbles form at the noztle from the very first moment, contrasting in that respect with the behaviour of jets of water projected into air (Fig. 1).

The latter is our next subject. This is the reservoir from which the water is supplied. It issues from a nozale of drawn-out glass, and at the moment of issue it consists of a cylindrical body of water. The cylindrical form is unstable, however, and the water rapidly breaks up into drops, which succeed one another so rapidly that they can hardly be detected by ordinary vision. But by

means of instantaneous photography the individual drops can be made evident 1 will first project the jet itself on the screen, in order that you may appreciate the subject which we shall see presently represented by photography. [Experiment] Along the first part of its length the jet of water is continuous After a certain point it breaks into drops, but you cannot see them because of their rapidity. If we act on the jet with a vibrating body, such as a tuning-fork, the breaking into drops occurs still earlier, the drops are more regular, and assume a curious periodic appearance, investigated by Savart. I have some photographs of jets of that nature Taken as described, they do not differ much in appearance from those obtained by Chichester Bell, and by Mr Boys We get what we may regard as simply shadows of the jet obtained by instantaneous illumination; so that these photographs show little more than the outlines of the subject They show a little more, on account of the lens-like action of the cylinder and of the drops Here we have an instantaneous view of a jet similar to the one we were looking at just now (Fig 2). This is the continuous part; it gradually ripples itself as it comes along; the ripples increase; then the contention becomes a kind of ligament connecting consecutive drops;

the ligament next gives way, and we have the individual drops completely formed. The small points of light are the result of the lens-like action of the drops (Other

instantaneous views also shown l

The pictures can usually be improved by diffusing somewhat the light of the spark with which they are taken. In front of the ordinary condensing lens of the magic lantern we slide not a penceensing, tens us time magic lantern we slide may be provided as a slightly oiled, and we then get better pictures she often more shading. [Photograph shown] I here is one owing more shading. [Photograph shown] I here is one done in that way, you would hardly be the control of a temor. looks more like mercury You will notice the long ligament trying to break up into drops on its own account, but not succeeding (Fig. 3)

There is another, with the ligament extremely pro-

longed. In this case it sometimes gathers itself into two drops (Fig 4). [A number of photographs showing slight variations

were exhibited]

The mechanical cause of this breaking into drops is, I need hardly remind you, the surface tension or capillary force of the liquid surface. The elongated cylinder is an unstable form, and tends to become alternately swollen and contracted. In speaking on this subject I have often been embarrassed for want of an appropriate word to describe the condition in question. But a few days ago, during a biological discussion, I found that there is a recognized, if not a very pleasant, word. The cylindrical jet may be said to become varicose, and the varicosity goes on increasing with time, until eventually it leads to absolute disruption.

There is another class of unstable jets presenting many points of analogy with the capillary ones, and yet in many respects quite distinct from them. I refer to the phenomena of sensitive flames. The flame, however, is not the essential part of the matter, but rather an in-dicator of what has happened. Any jet of fluid playing

into a stationary environment is sensitive, and the most convenient form for our present purpose is a jet of coloured in uncoloured water. In this case we shall use a solution of permanganate of potash playing into an atmosphere of other water containing acid and sulphate of iron, which exercises a decolourising effect on the permanganate, and so retards the general clouding up of the whole mass by accumulation of colour. [Experiment.] Mr. Gordon will release the clip, and shall get a jet of permanganate playing into the liquid. If everything were pefectly steady, we might see a line of purple liquid extending to the bottom of the trough; but in this theatre it is almost impossible to get anything steady The instability to which the jet is subject now manifests itself, and we get a breaking away into clouds something like smoke from chimneys. A heavy tuning-fork vibrating at ten to the second acts upon it with great advantage, and regularizes the disruption. A little more pressure will increase the instability, and the jet goes suddenly into confusion, although at first, near the nozzle, it is pretty regular

It may now be asked "What is the jet doing?" That

is just the question which the instantaneous method

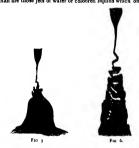

enables us to answer For this purpose the permanganate which we have used to make the jet visible is not of much service. It is too transparent to the photographic rays, and so it was replaced by bichromate of potash. Here the opposite difficulty arises, for the bichromate is invi-sible by the yellow light in which the adjustments have to be made I was eventually reduced to mixing the two materials together, the one serving to render the jet visible to the eye and the other to the photographic plate. Here is an instantaneous picture of such a jet as was before you a moment ago, only under the action of a regular vibrator It is sinuous, turning first in one direc-tion and then in the other The original cylinder, which is the natural form of the jet as it issues from the nozzle, curves itself gently as it passes along through the water. It thus becomes sinuous, and the amount of the sinuosity increases, until in some cases the consecutive folds come into collision with one another [Several photographs of sinuous jets were shown, two of which are reproduced in Figs. 5 and 6]
The comparison of the two classes of jets is of great

interest. There is an analogy as regards the instability, the vibrations caused by disturbance gradually increasing as the distance from the nozzle increases, but there is a

great difference as to the nature of the deviation from the great unterince as to me nature of the deviation from the equilibrium condition, and as to the kind of force best adapted to bring it about. The one gives way by becoming varicose; the other by becoming smuous The only forces capable of producing varicosity are symmetrical forces, which act alike all round. To produce simuosity, we want exactly the reverse—a force which acts upon the

iet transversely and unsymmetrically. I will now pass on to another subject for instantaneous photography—namely, the soap film. Everybody knows that if you blow a soap bubble it will break—generally before you wish. The process of breaking is exceedingly rapid, and difficult to trace by the unaded eye. If we can get a soap film on this ring, we will project it upon the screen and then break it before your eyes, so as to enable you to form your own impressions as to the rapidity of the operation. For some time it has been my ambition to photograph a soap bubble in the act of breaking. I was prepared for difficulty, believing that the time occupied was less than the twentieth of a second. But it turns out to be a good deal less even than that. Accordingly the subject is far more difficult to deal with than are those jets of water or coloured liquids which one

can photograph at any moment that the spark happens to

come
There is the film, seen by reflected light One of the first difficulties we have to contend with is that it is not easy to break the film exactly when we wish. We will easy to break the film exactly when we wish. We will drop a shot throught at The shot has gone through, as you see, but it has not broken the film, and when the syou see, but it has not broken the film, and when the any number of times from a moderate height without pro-ducing any effect. You would suppose that the skap in going through would necessarily make a hole, and end the life of the film. The shot goes through, however, without making a hole. The operation can be traced, not very well with a shot, but with a ball of cork stuck on the end of a pin, and pushed through. A dry shot does not readily break the film; and as it was necessary for our purpose to effect the rupture in a well-defined manner, here was a difficulty which we had to overcome. We found, after a few trials, that we could get over it by wetting the shot with alcohol.

We will try again with dry shot. Three shots have gone through and nothing has happened. Now we will try one wetted with alcohol, and I expect it will break the film at once. There ! it has gone !

The apparatus for executing the photography of a NO. 1133, VOL. 44]

breaking soap film will of necessity be more complicated than before, because we have to time the spark exactly than before, because we have to time the spark exactly with the breaking of the film. The device I have used is to drop two balls simultaneously, so that one should determine the spark and the other rupture the film. The most obvious plan was to hang iron balls to two electro-magnets, and cause them to drop by breaking the circuit, so that both were let go at the same moment. The method was not quite a success, however, because there was apt to be a little hesitation cess, however, because there was apt to be a little hesuation in letting go the balls. So we adopted another plan. The balls were not held by electro-magnetism, but by springs (Fig. 8) pressing laterally, and these were pulled off by electro-magnets. The proper moment for putting down the key and so liberating the balls, is indicated by the tap of the beam of an attracted disk electrometer as it strikes against the upper stop. One falling ball deter-mines the spark, by filling up most of the interval between two fixed ones submitted to the necessary electric pressure Another ball, or rather shot, wetted with alcohol, is let go at the same moment, and breaks the film on its passage through it. By varying the distances dropped through, the occurrence of one event may be adjusted relatively to the other. The spark which passes adjusted relatively to the other. The spark which passes to the falling ball is, however, not the one which illuminates the photographic plate. The latter occurs within the lantern, and forms part of a circuit in connection with the outer coatings of the Leyden jars, the

whole arrangement being similar to that adopted by Prof Lodge in his experiments upon alterna-tive paths of discharge. Fig 8 will give a general idea of the disposition of the apparatus. [Several photographs of breaking films were shown upon the screen; one of these is reproduced in Fig. 7.]2

This work proved more difficult than I had expected;

and the evidence of our photographs supplies the explanation-namely, that the rupture of the film is an extraordinarily rapid operation. It was found that the whole difference between being too early and too late was represented by a displacement of the falling ball through less than a diameter, viz. 1 inch nearly. The drop which we gave was about a foot. The speed of the ball would thus be about 100 inches per second; therefore the whole difference between being too soon and too late is represented by n_{00}^{+} second. Success is impossible, unless the spark can be got to occur within the limits of this short interval Prof. Dewar has directed my attention to the fact that

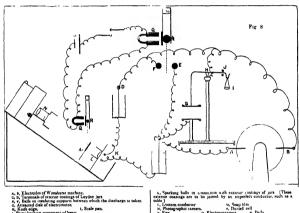

Dupré, a good many years ago, calculated the speed of rupture of a film. We know that the energy of the film is in proportion to its area. When a film is partially broken, some of the area is gone, and the corresponding potential energy is expended in generating the velocity of

In practice there were two sets of three jurs each The appearance of the breaking bobble, as seen under instantaneou unmanton, was first described by Marangonn and Stephanelli, Nese

the thickened edge, which bounds the still unbroken por-tion. The speed, then, at which the edge will go depends upon the thickness of the film. Dupré took a rather extreme case, and calculated a velocity of 32 metres per second. Here, with a greater thickness, our velocity was, perhaps, 16 yards a second, agreeing fairly well with

I now pass on to another subject with which I have lately been engaged—namely, the connection between aperture and the definition of optical images. It has long been known to astronomers and to those who study optics that the definition of an optical instrument is proportional to the aperture employed; but I do not think that the theory is as widely appreciated as it should be I do not know whether, in the presence of my colleague, I may venture to say that I fear the spectroscopists are

lenses may be. In accordance with the historical deve-lopment of the science of optics, the student is told that the lens collects the rays from one point to a focus at another; but when he has made further advance in the science he finds that this is not so. The truth is that we are in the habit of regarding this subject in a distorted manner. The difficulty is, not to explain why optical images are imperfect, no matter how good the lens employed, but rather how it is that they manage to be as good as they are. In reality the optical image of even a mathematical point has a considerable extension; light coming from one point cannot be concentrated into another point by any arrangement. There must be diffusion, and the reason is not hard to see in a general way. Consider what happens at the mathematical focus, where, if anywhere, the light should all be concentrated. At that point all the rays coming from the original radiant

among the worst sinners in this respect. They constantly speak of the dispersion of their instruments as if that by itself could give any idea of the power employed. You may have a spectroscope of any degree of dispersion, and yet of resolving power insufficient to separate even the D lines. What is the reason of this? Why is it that we cannot get as high a definition as we please with a limited aperture? Some people say that the reason why large telescopes are necessary is, because it is only by their means that we can get enough light. That may be in some cases a sufficient reason, but that it is inadequate in others will be apparent, if we consider the case of the sun. Here we do not want more light, but rather are anxious to get rid of a light already excessive. The principal raison d'Ure of large telescopes 18, that without a large aperture definition 18 bad, however perfect the

sction with exterior coatings of jars. [These joined by an imperfect conductor, such as a

o. Electro-magnets

point arrive in the same phase. The different paths of the rays are all rendered optically equal, the greater actual distance that some of them have to travel being compensated for in the case of those which come through the centre by an optical retardation due to the substitution of glass for air; so that all the rays arrive at the same time. If we take a point not quite at the mathematical focus but near it, it is obvious that there must be a good deal of light there also The only reason for any diminution at the second point lies in the discrepancies of phase which now occur, and these can only enter by degrees. Once grant that the image of a mathematical point is a diffused patch of light, and it follows that there must be a limit to definition The images of the com-

On this principle we may readily calculate the focal lengths of lenses without use of the law of sines (see Phri. Mag., December 1879).

NO. 1133, VOL. 44]

ponents of a close double point will overlap; and if the distance between the centres do not exceed the diameter of the representative patches of light, there can be no distinct resolution. Now their diameter varies inversely as the aperture; and thus the resolving power is directly as the aperture

My object to-night is to show you by actual examples that this is so I have prepared a series of photographs of a grating consisting of parallel copper wires separated by intervals equal to their own diameter, and such that the distance from centre to centre is 10 inch. The grating was backed by a paraffin lamp and large condensing lens; and the photographs were taken in the usual way, except that the lens employed was a telescopic object-glass, and was stopped by a screen perforated with a narrow adjustable slit, parallel to the wires 1 In each case the exposure auce sur, parallel to the wires. In each case the exposure was invertely as the aperture employed. The first [thrown upon the screen] is a picture done by an aperture of eight hundredths of an inch, and the definition is tolerably good. The next, with six hundredths, is rather worse. In the third case, if think that everyone can see that the definition is deteriorating; that was done by an aperture of four hundredths of an inch. The next is one aperture or four numeredins of an inch. I he next is one done by an aperture of three hundredths of an inch, and you can see that the lines are getting washed out. In focusing the plate for this photograph I saw that the lines had entirely disappeared, and I was surprised, on developing the plate, to find them still visible. That was in virtue of the shorter wave-length of the light operative in photography as compared with vision In the last example, the aperture was only two and a half hundredths of an inch, and the effect of the contraction has been to wash away the image altogether, although, so far as ordinary optical imperfections are concerned, the lens was acting more favourably with the smaller aperture than with the larger ones

This experiment may be easily made with very simple apparatus, and I have arranged that each one of my audience may be able to repeat it by means of the piece of gauze and perforated card which have been distributed The piece of gauze should be placed against the window so as to be backed by the sky, or in front of a lamp provided with a ground-glass or opal globe. You then look at the gauze through the pin-holes. Using the smaller hole, and gradually drawing back from the gauze, smaller note, and gradually drawing back from the gause, you will find that you lose definition and ultimately all sight of the wires. That will happen at a distance of about 44 feet from the gauze 1f, when looking through the smaller hole, you have just lost the wires, you shift the card so as to bring the larger hole into operation,

you will see the wires again perfectly

That is one side of the question However perfect your lens may be, you cannot get good definition if the aperture is too much restricted. On the other hand, if the aperture is much restricted, then the lens is of no use, and you will get as good an image without it as

I have not time to deal with this matter as I could wish, but I will illustrate it by projecting on the screen the image of a piece of gauze as formed by a narrow aperture parallel to one set of wires. There is no lens whatever between the gauze and the screen. [Experi-ment] There is the image—if we can dignify it by such a name-of the gaure as formed by an aperture which is a name—of the gaure as ionincia by an aperture is gradually narrowed, we will trace the effect upon the definition of the wires parallel to it. The definition is improving; and now it looks tolerably good. But I will go on, and you will see that the definition will get bad again. Now, the aperture has been further narrowed, and the lines are getting washed out. Again, a little more, and they are gone. Perhaps you may think that the explanation lies The distance between the grating and the telescope lens was 12 feet

In the faintness of the light. We cannot avoid the loss of light which accompanies the contraction of aperture but to prove that the result is not so to be explained, I will now put in a lens. This will bring the other set of wires into view, and prove that there was plenty of light to enable us to see the first set if the definition had been good enough. Too small an aperture, then, is as bad as one which is too large, and if the aperture is sufficiently small, the image is no worse without a lens than with one

What, then, is the best size of the aperture? That is remain stem, is the best size of the aperture? That is the important question in draling with pin-hole photography. It was first considered by Prof. Petrval, of Vienna, and he arrived at the result indicated by the formula, $2r^2 = f\lambda$, where 2r is the diameter of the aperture, A the wave-length of light, and f the focal length, or rather simply the distance between the aperture and the screen upon which the image is formed

His reasoning, however, though ingenious, is not sound, regarded as an attempt at an accurate solution of the question. In fact it is only lately that the mathematical problem of the diffraction of light by a circular hole has been sufficiently worked out to enable the question to be solved. The mathematician to whom we owe tion to be solved. The mathematician to whom we owe this achievement is Prof. Lommel. I have adapted his results to the problem of pin-hole photography [A series of curves (Philosophead Magazim, February 1891), were shown, exhibiting to the eye the distribution of illumination in the images obtainable with various apertures j The general conclusion is that the hole may advantageously be enlarged beyond that given by Petzval's

advantageously be enlarged beyond that given by Petrval's rule. A sutable radius sir = \(\sigma(1) \) with the own out on the procession of the procession was 0 07 inch, and the distance of the 12 × 10 plate from the aperture was 7 feet. The resulting picture of a group of cedars shows nearly as much detail as could be seen direct from the place in question

THE SMITHSONIAN ASTRO-PHYSICAL OBSERVATORY

THE Smithsonian Institution, as we have already announced, has established as one of its departments a Physical Observatory which, with the instru-ments, has been supplied from the Smithsonian Fund It occupies at present a temporary structure, though funds have been subscribed for a permanent building tunus nave open subscribed for a permanent building when Congress shall provide a suitable site. For the maintenance of the Observatory an appropriation has been made by Congress which became available on July 1. The actual instrumental work of the new Observatory will necessarily devolve largely upon a senior and a junior assistant, who can devote their entire time to research, and it is hoped that with the improved apparatus it will be possible to prosecute advantageously investigations in telluric and astro-physics, and particularly those with the bolometer in radiant

In accepting the position of assistant secretary of the Smithsonian Institution in 1887, Mr. Langley retained the Directorship of the Observatory at Allegheny for the purpose of completing the researches begun there, and after his appointment as Secretary of the Institution, he still continued the titular Directorship, though but a duties at the capital. With the completion of the equipment of the little Observatory at Washington, he, however, formally resigned, on April 30, the Directorship at Allegheny, which he had held since 1887; and he will, so far as his administrative occupations permit, give

vestigations.

The class of work which is referred to does not ordinarily involve the use of the telescope, and that which is contemplated is quite distinct from what is carried on at present at any other Observatory in the United States The work for which the older Government Observatories at Greenwich, Paris, Berlin, and Washington were founded, and in which they are now chiefly engaged, is the determination of relative positions of heavenly bodies, and our own place with reference to them. Within the past twenty years all these Governments, except that of the United States, have established astrophysical Observatories, as they are called, which are, as is well known, engaged in the study of the heavenly bodies as distinct from their positions-in determining, for instance, not where, but what, the sun is, how it affects terrestrial climate and life, and how it may best be studied for the purposes of the meteorologist, and for other uses of an immediately practical nature

The new Observatory is established for similar purposes. Its outfit includes a very large siderostat (recently completed by Grubb), which is mounted in such a way as to throw a beam of light horizontally in the meridian It is intended to carry a mirror of 20 inches diameter, and is perhaps the most massive and powerful instrument of its kind ever constructed. Within the dark room is mounted another large instrument—the spectrobolometer -which is, in effect, a large spectroscope with 20-inch circle reading to 5 seconds of arc, specially designed for use with the bolometer It was made by William Grunow and Son, of New York, as the outcome of Mr. Langley's experience with smaller apparatus during his earlier investigations. The most important part of the instrumental equipment is completed by specially designed galvanometers, scales, and a peculiar resistance box, and these three instruments, used in conjunction with the bolometer, and perhaps with the aid of photography, will be employed in the investigations upon light, heat, and radiant energy in general, for which the Observatory is primarily intended, though some departments of terrestrial physics may also receive attention

THE NEW GALLERY OF BRITISH ART.

WE believe that the Committee appointed by the Corporation to consider the question of the grant of a site on the Embankment for the new gallery will soon make its report. The Pall Mail Gazette of Tuesday says:—"There is a vacant piece of just one acre at Black-firars, on the land acquired some years ago and cleared of the old City gas-works by the Corporation. This land originally cost some £260,000, and on portions of it have been erected the City of London School and Sion College. The value of the entire holding has increased to at least £550,000; so that if the proposed piece, which is valued at about £120,000, were made over by the Corporation for the Art Gallery, the City would still be a gainer of some £170,000 by the transaction."

In the meantime, public opinion is rapidly growing, not only in favour of some of our national buildings devoted to art finding a home in the City, but also against the site at South Kensington—bought for scientific purposes, and required to meet existing needs-being diverted

from its proper and natural use

Both these views are expressed in the following
Memorial, which, although circulated chiefly among

men of science during the last few days, contains the names of many representative men in other branches It has been transmitted to the Lord Mayor during the present week.

Memorial to the Right Honourable the Lord Mayor of London

WF, the undersigned, having heard that there is a possibility of the City of London finding a site on the Embankment for the National Gallery of British Art, which a munificent donor has proposed to build, venture to approach Your Lordship with our earnest request that you will yourself support, and use your best endeavours to urge upon the City authorities, the very great importance of giving effect to this proposal.

The memorial already presented to the Prime Minister will have made Your Lordship aware of the many strong objections, from the scientific point of view, to the site which was suggested for the gallery in the first instance

It is innecessary for us, therefore, to say more on this subject, except to remark that the greatest city in the world must be the first to suffer if, from any cause, the proper presentation of science and means for its study by its citizens are in any way crippled

By affording a site on the Embankment, Your Lordship and the authorities you represent will be the means of preventing the lamentable result to which we have referred, and you and they will earn the gratitude of all interested in scientific progress, as well as confer a great boon on the art-loving public

Among the signatories of the Memorial are the following -

CARDINAL HAYNALD.

THE death of Cardinal Haynald, Archbishop of Kalocsa, is announced in the daily papers as having taken place on Saturday, the 4th inst It was not an unexpected event, as his health had been gradually getting worse for some two or three years Last year he celebrated the jubilee of his priesthood, and Dr. A Kanits, Professor of Botany in the University of Klausenburg, made it the occasion of publishing a eulogy on him as a botanist This was translated into French by Prof. E. Martens, of Louvain Although an excellent botanist, Cardinal Haynald was better known as a patron of botany than as a contributor to botanical literature For the following particulars of his life and work we are mainly indebted to Dr Kanitz's memoir

Cardinal Haynald was born about 1816 His taste for botany was inherited from his father, who himself possessed a fine herbarium During his stay at Vienna, in the Augustinaum, a theological college, he became acquainted with Edward Fenzl, then assistant curator of the botanical department of the Court, under whose tuition his botanical studies took a more practical shape priestly duties, however, did not allow him to follow his favourite study until he was appointed Bishop of Transylvania, when he began to investigate the flora of this vania, when he bogan to investigate the flora of this country with indefantgable zeal. He became Archbishop of Karthago, and afterwards of Kalocsa, and after the accession of Lee the Tenth to the Papal chair, a Cardinal. He was a long time a prominent member of the Hungarian House of Magnates, and from 1873 also a member of the Royal Hungarian Academy of Science Although always overburdened by the sacerdotal, political, and social duties of his high position, he found time to continue his botanical studies. He published only a few botanical papers, partly on Hungarian plants, and partly biographical sketches of botanists with whom he was more intimately acquainted, as Fenzl, Parlatore, and Boissier. His greatest merit, however, from a scientific point of view, was the assistance which he gave to botanical studies in Hungary by establishing a great private herbarium, which he placed in the most liberal way at anybody's disposal, and by the magnanimous generosity with which he

always supported botanical enterprise, both in Hungary and abroad. The herbarium at his residence gary and abroad. The herbarium at his resument at Kalocsa was not only the richest in Hungary, but one of the largest private collections on the Continent. It was largely formed by the purchase of the herbaria of Heuffel, Schott, Kotschy, and Sodiro Besides these and the plants collected by himself, he acquired most of the collections which have been distributed by subscription.

Hungary loses in Cardinal Haynald one of her greatest patriots, who was an honour to his profession, as well as to science, of which he was always a generous benefactor Schur named after him a genus of grasses, founded on Secale villosum, Linn., which is reduced by Bentham and Hooker to Agropyrum, and Kanitz a genus of Lobeliaceæ.

OXFORD SUMMER MEETING OF UNIVERSITY EXTENSION STUDENTS

THE process by which University Extension is carried throughout the country and made a vehicle for the further education of the adult student is well known, and is gradually becoming more and more appreciated in proportion as those who are responsible for the method improve the lines on which it is carried out. machinery employed embraces lectures, classes, travelling libraries, &c., but one element vitally necessary to the University student is not supplied by these aids. This element is that of residence, and it was a happy sugelement is that of residence, and it was a happy sug-gestion on the part of the originators to propose that, for one month in the Long Vacation, arrangements should be made by which those who have profited by being brought into contact with a University lecturer should enjoy the additional advantage of being brought under the charm that haunts the colleges and closters of Oxford and Cambridge

The Oxford summer meeting commences on July 31, and is continued throughout the month of August, but, for the benefit of students who are unable to be present during so long a period, the course is divided into two sections, the second commencing on August 12. It has been found desirable to remove as far as possible the fragmentary and isolated character of the lectures given at these meetings, and therefore, while the course will be complete and independent in itself, it will also form the first part of a cycle of study which for its full development

will embrace a period of four summers

That these lectures propose something more than to
add piquancy to an agreeable picnic will be shown from
the following slight sketch of the subjects treated—and treated by authorities of acknowledged reputation To take the lectures on natural science first in physiology, Mr Poulton will discuss the recent enticisms of Weismann's theory of heredity, and Mr Gotch will lecture on the functions of the heart. In chemistry, Prof. Odling lectures on the benzene ring, and under the supervision of Mr Marsh a course of practical chemistry will be conducted in the laboratory of the University Museum In geology, a course of practical instruction will be given by Prof Green and Mr. Badger, to include excursions in the neighbourhood of Oxford clude excursions in the neighbourhood of Voltoria A class in practical astionomy will be welcomed at the University Observatory; while electricity finds an able exponent in Mr. G. J. Burthe. But the distinguishing feature of this meeting is the attention given to agricultural science "designed for agricultural audiences under County Council schemes". This designation seems somewhat vague, and it will be very interesting to see the character of the audience attracted by this title. Four lectures are offered the first is entitled, "The application character of the audience attention of Aortculture." This description is sufficiently wide, but does not indicate whether the lecture is intended as a sample of those which State-aided Board

schools in agricultural districts might well offer to lade who have passed through the successive standards, or as one addressed to the sons of farmers, and supplying that form of instruction which it is the duty of agricultural colleges to impart. Another lecture is offered on the management of poultry. This is more definite and more hopeful; and when we remember that the students who come up for these summer meetings are, for the most part, ladies, who can well be supposed to take an intelligent interest in this part of farming operations, we must admit that the subject is well chosen. Manures of various admit that the subject in the other two lectures, and

will be doubtless of a sufficiently technical character. The literature and history lectures are of special interest, and by the combination of many lecturers are made to cover with great completeness the mediurval new orders of the conference of the control of the conference of th

THE PROPOSED TEACHING UNIVERSITY FOR LONDON.

ON Monday, at the Council Office in Downing Street the Universities Committee of the Privy Council, consisting of the Lord President of the Council (Viscount Crarbono), the Earl of Selborne, Lord Monk Birtton, Lord Basing, and Lord Sandford, reassembled for the purpose of giving their decision on the pettion of King's and University Colleges for the grant of a charter for the establishment of a Teaching University for London

The Earl of Selborne, in giving the opinion of their Lordships upon the draft charter of the proposed University, said, with regard to the opposition of the existing University of London, that some of the objections made might be treated as disallowed — It had been understood by their Lordships that a minimum course of two years' study at the new University would be required. It that was so, their Lordships were satisfied, and would say no more upon the point. The objections put forward by the medical faculty were generally disallowed. The word "London" would have to be omitted from the charter, but the University might be called either "the Albert University" or "the Metropolitan University." With regard to the suggestion that ten members of the Faculty of Medicine should be elected to the Council, their Lordships were of opinion that the medical schools should fill five places upon that body, or, if it were pre-ferred, that each school should elect one member for the Medical Board of Study. If the Royal Colleges and the medical schools agreed to come in together, however, the number of members on the Council might be raised. Their Lordships did not approve of the proposed strength of the Council, and thought that four of the places might be accorded to the Faculty of Law. Teachers in any branch of science, their Lordships considered, should be branch of science, their Lordships considered, should be admitted as members of the Science Faculty, and the six places on the Connoi which it was proposed to give the state of the Connoi which it was proposed to give soft paragraph of the Royal Commissioners' Report I if the medical schools and colleges declined to come in at first, provision ought to be made to allow them to do so in the future. Their Lordships thought that a place upon the Council might be given to the Apochecancer Society, but they were not disposed to insist upon that being done The view of their Lordships upon the question of honorary degrees was that no such degrees should be granted in medicine, and that the holding of an honorary

degree should be no qualification for election to the Council. The ordinary degree in medicine should not be granted until the whole of the prescribed conditions had been fulfilled.

NOTES

This decision of the Universities Committee of the Prity Council with regard to the proposed new University for London is one that might have been expected from a body of non-experts. It is hastly, and will give satisfaction to no one by whom the subject has been seriously considered. It may throw back the higher teaching in London for half a century.

Mr. WALTER BESANT, in an imaginary "Page from the Kauer's Dury," notes that there are not to be seen at Court any of "the people who make the real greatness of the country—this traders, its manufactures, it men of science, art, and literature." It has been remarked that in this respect the Guy Corporation, last Friday, followed the example of the Court, no representative of science, or literature, or art, as such, having been invited to the Guidhall banquet. It would have been better to follow the precedent set at the time of the Cara's visit when a large number of the leading scientific me were asked to the reception at the Foreign Office, and were personally presented

At the ensuing British Association meeting at Cardiff, it is proposed to hold in Section A, if possible in conjunction with Section C, a discussion on "Units and their Nomenclature," having special regard to the new electrical and magnetic units now becoming necessary for practical purpose.

This Secretary of State for India in Council has appointed, on the nomination of the Government of India, the following persons to represent it on the permanent governing body of the imperial Institute, for the year ending April 30, 1892 — W. T. Thiselton-Dyer, C. M.G., F. R. S., Director, Royal Gardeni, Kew, General James T. Walker, R. E., C. B. F. R. S., late Surveyor General of India, John W. P. Murc-Mackenin, Arrachitural Department of India Revenue and Arrachitural Department

SIR J. D. HOOKER has been elected a Foreign Member of the Academy of Sciences in Buda-Pesth.

THE Secretary of Sitte for the Colones has appointed, on the normalism of Kew, Mr C. A Barber, late Scholar of Christ's College, Cambridge, and University Demostrator in Busary, to be Superintendent of the recently created Agricultural Department of the Leeward Islands. The Superintendent will recide in Antiqua, and will have the general supervision of the botanness statistics at Antiqua, Dommies, Montserrat, and St. Kitts-News.

THE Council of University College, Liverpool, have appointed Mr Francis Gotch, of Oxford, to their new Chair_of Physiology.

THE Foreign Office has expressed the wish that the "Flora of Tropical Africa," prepared at Kew under the editorship of Prof. Oliver, and of which three volumes have appeared, should be continued and completed it is calculated that four more volumes will be required, and the Treasury has sanctioned a scheme by which the necessary funds will be provided.

THE Accademia dei Lances of Rome has awarded to Prof Saccardo, of Padus, in acknowledgment of his labours in mycology, the Royal prize of 10,000 francs intended for the encouragement of morphological researches. THE Government has appointed the Council of the Society of Arts as a Royal Commusion to direct the formation of the Bittath Section at the Chicago Exhibition. If we may ladge from the preparations which are being made in America, the Exhibition as likely to be one of great splendour One of its attractions will be a collection of objects relating to ethnology and archaelogy. This is being organized by Prof. Petanam.

A COMMITTEE, as we recently stated, has been appointed for be reorganization of the Natural History Museum as Paris. By some who interest themselves in the question it is proposed that the Museum should be made the only institution in Paris for the study of natural history. According to this scheme, all natural history cleans in the Sorbone and elsewher would be matural history proper would also disappear. The professors would have to examine all candidates in natural history proper would also disappear. The professors would have to examine all candidates in natural receive.

A COMMITTEE appointed by the Photographic Soldiny of Great Binata has presented a preport on the proposal that the photographic solcities of the United Kingdom should unter more closely for the better promotion of their common interests. The Committee advises that it should be open to photographic societies to sallitate themselves to the Photographic Society of Great Binatin , and suggestions are made as to the way in which stillation should be effected

TRE 5fth season of the Ednburgh Vacation Courses will begin on August 3. M. Espinas, Prefessor of Philosophy and Dean of the Faculty of Letters in the University of Bordeans, Passabe sha been charged by his Government to report upon the educational scheme and methods of these courses, and also teletres to tional scheme and methods of these courses, and also teletres to maquer into Southin higher education generally. Dr. H. de the Vangray, who will deliver a series of factures on general biology, who will deliver a series of factures on general biology. Extension movement. The expected presence of these and other the sales to the present passable that it might be well to hold, that Ednburgh, a small informal Congress, or rather a short series of meetings, for the discussion of currentle, higher educational methods, and other questions of immediate interest. Particulars on this subset will shortly be a announced.

THE Royal Society of Antiquaries of Ireland hold their general meeting in the Town Hall, Killarney, on August 11. Excursions are planned for every day, except Sunday, from August 11 to 20

THE Royal Archeological Institute will hold its annual meeting at Edinburgh from August 11 to 18 Sir Herbert Maxwell will preside

THE German Anthropological Society will hold its twentysecond annual meeting at Danzig, from August 3 to 5

HER MAJESTY'S Commissioners for the Exhibition of 1851, assisted by a committee of gentlemen experienced in acientific education, have made the following appointments to Science Scholarships for the year 1891. The scholars have been bondfide students of science for at least three years, and were nominated for the Scholarships by the authoritles of their respective Universities or Colleges. The Scholarships are of the value of £150 a year, and are tenable for two years (subject to a satisfactory report at the end of the first year) in any University at home or abroad, or ln some other institution to be approved of by the Commissioners. The scholars are to devote themselves exclusively to study and research in some branch of science the extension of which is important to the industries of the country. A Scholarship was offered to the University of Sydney, but the Council found themselves unable to nominate a suitable candidate. Nominating institution-University of Edinburgh, scholar-John Shields, institution to which scholar pro-

a Continental University, probably Leipzig; University of Glaagow, James H. Gray (a), University of Glaagow; University of St. Andrews, William Frew, Univer-sity of Munich, Mason Science College, Birmingham, John Joseph Sudborough, University of Heidelberg, University College, Bristol, Frederick Benjamin Fawcett (a), University College, Bristol; Durham College of Science, Newcastle-on-Tyne, William M'Connell, jun (a), Durham College of Science; Yorkshire College, Leeds, Harry Ingle, a German University, probably Wurzburg; University College, Liverpool, Robert Holt (a), University College, Liverpool : Owens College, Manchester, Thomas Ewan, Owens College, first year, University College, Nottingham, Edwin H Barton (b). South Kensington, Firth College, Sheffield, Annie J Hoyles (a), Firth College, Sheffield; University College of South Wales and Monmouthshire, Franke Herbert Parker, first year same College, second year a German University; Queen's College, Belfast, Benjamin Moore, University of Leipzig; Royal College of Science for Ireland, Frederick William Dunn, first year University of Glasgow, second year Berlin, M'Gill University, Montreal, Percy Norton Evans, University of Berlin, and probably other German Universities; University of Melbourne, William Huey Stecle (a), University of Melbourne, (a) These scholars have been recommended to spend part of the term of scholarship at some other institution (b) This appointment is conditional on the candidate passing examination for B.Sc London

Titoss who require power for electric lighting may be interested to know that Messra. Prestman Brothers have a good account to give of the success of their oil-engine. Many orders have been received for engines varying in sue from 1 to 25 actual hp. for electric lighting, and Messrs Prestman, in order to meet the growing demand, have largely extended their works

ACCORDING to a telegram sent through Reuter's Agency from San Francisco, July 11, an enormous cavern in Josephine County, Oregon, at a point twelve miles north of California and forty from the coast, has been discovered. It has two openings, and contains many passages of great beauty 'There are numbers of semi-transparent stalactites, several giant milk-white pillars, and a number of pools and streams of clear, cool water A week was spent in exploring the cavern, and innumerable passages and chambers were discovered. On penetrating one of these passages for a distance of several miles, the exploring party came across a lake of clear water and a waterfall thirty feet high All kinds of grotesque figures were found in the various chambers; but the only signs of animal life were discovered a short distance from the entrance, where a few bones were found, indicating that bears had carried their prey there. The cavern appears to be fully as large as the Mammoth Cave in Kentucky.

DR D PRAIN, Curator of the Calcutta Herbarium, has published an the Journal of the Assute Society of Rengal, and separately, a memor on new Indian Labatas. Nearly fifty speecks, belonging to upwards of twenty genera, are added to those described in the "Flores of British India." They are mostly from frontier extensions of the Empire, some from the east, some from the east, some from the west; and nearly half of the species are new to science. Specially interesting among these is Frait's new genus Microfesas, founded upon the Pitternsthus Pattlewist, new genus Microfesas, founded upon the Pitternsthus Assum. The first has since Calcutted and South-Eastern Calcutted and S

scholar—John Shields, institution to which scholar proposes to attach himself—University of Edinburgh and Prof. G. Bonnier, with the assistance of a number of botanists, will be published under the auspices of the Minister of Public Instruction of France

The annual publication of the very meful. "Correspondance totainque" ceased with the death of its editor, Prof. E. Morreo, of Lidge. With the aim of supplying its place, the International Library, 4 Rue de la Sorbonne, Parls, has now issued a "Nowelle Correspondance boatingue, liste des botanties de totas les pays, et des établissements, sociétés, et journanx de botanties."

PRINCE ROLAND BONAPARTE has issued, at his own expense, a handsome book on Corsica, recording his travels and the history of the island. He also gives a full bibliography relating to the subject,

A NEW quarterly scientific journal has made its first appearance in Parls, under the title Revue des Sciences naturelles de POuest, devoted to the interests of zoology, boiany, geology, mineralogy, anthropology, embryology, and teratology.

A MONTHLY journal of natural science, which may have many opportunities of doing good work, has just been started in Malia. It is called *The Mediterr anean Naturalist*, and is edited by Mr. John H. Cooke, F.G. S.

THE "Dictionnaire d'Agriculture," by J A Barral and H. Sagnier, will soon be completed. Vol. iv is nearly ready, and will be quickly followed by Vol. v.

A NEW edition of the Great Eastern Railway Company's "Tourist Guide to the Continent," edited by Mr Percy Lindley, has been published New, editions of Mr. Lindley's "Walks in the Ardennes" and "Walks in Epping Forest" have also been published, and he has compiled two other useful little hand-books, "Walks in Holland," and "Holdskys in Belgium,"

Masses Guy and Co., Cork, send us "Guy's South of Ireland Pictorial Guide," in which are described and illustrated much fine scenery and various things interesting to students of natural history and archeology

MESSRS DULAU AND Co. have issued a catalogue of the works on geology which they are offering for sale.

THE results of an investigation concerning the cause of the insolubility of pure metals in acids are contributed by Dr. Weeren to the current number of the Berichte De la Rive, so long ago as the year 1830, pointed out that chemically pure zinc is almost perfectly insoluble in dilute sulphuric acid Hitherto, however, the hypotheses put forward attempting to account for this singular fact have been anything but satisfactory The theory of Dr Weeren is extremely simple, and is fully supported by the most varied experiments, physical and chemical It may be stated as follows "Chemically pure zinc and also many other metals in a state of purity are insoluble or only very slightly soluble in acids, because, at the moment of their introduction into the acid, they become surrounded by an atmosphere of condensed hydrogen, which under normal circumstances effectually protects the metal from further attack on the part of the acid" It is found that when a piece of pure zinc is immersed in dilute sulphuric acld, a slight action does occur during the first few succeeding moments. zinc sulphate and free hydrogen being formed in minute quantity The free hydrogen, however, instead of escaping, becomes condensed by the molecular action of the zinc upon the surface of the latter, and is retained there with great tenacity as a thin mantle of highly compressed hydrogen gas, capable of affording perfect protection against further inroad of the acid. The experiments from which this simple and very probable explanation has been derived were briefly as follows. The amount of chemically pure zinc dissolved by the acid was first determined It was, of course, an exceedingly minute quantity. Considering this amount as unity, it was next sought to determine what

difference would be effected by performing the experiment in vacuo, when of course the escape of the hydrogen would be greatly facilitated. The solubility was found under these circumstances to be increased sevenfold. Next the experiment was performed at the boiling temperature of the dilute acid, first when ebuilition was prevented by increasing the pressure, and secondly when ebullition was unhindered, thus again facilitating the removal of the hydrogen film. In the first case, when chullition was prevented, the solubility was practically the same as in the cold, while in the second case, with uninterrupted ebullition, the solubility was increased twenty-four times. Finally, experiments were made to ascertain the effect of introducing into the acid a small quantity of an oxidizing agent capable of converting the hydrogen film to water. When a little chromic acid was thus introduced the solubility was increased 175 times, and when hydrogen peroxide was employed the solubility was increased three hundred-fold The explanation of the case with which the metal becomes attacked when the ordinary impurities are present is that the hydrogen is not their liberated upon the surface of the zinc, but rather upon the more electro negative impurities, leaving the pure zinc itself open to the continued attack of the I he same of course occurs when a plate of platinum is placed in contact with a plate of pure zinc in the acid. The action of nitric acid, the only common acid which does attack pure metals, is evidently due to the oxidation of the hydrogen film by further quantities of the acid, with formation of water and production of the lower oxides of nitrogen, and even under certain circumstances of ammonia

Tits additions to the Zoological Society's Gardens during the past week include a Macsque Monkey (Manacur gementique) from India, presented by Mr. R. Armstrong, two Senegal Touncous (Greythans prens) from West Afren, presented by Sir Brandforth Griffith, Barr , two Rock Thrushes (Montrole Sanatial) from India, presented by the Rev Hubert D Aviley, two Larger Hill Mynahs (Graudis internatia) from China, deposited, two Maile Dere (Garana maneris), Hire Summer Ducks (Ar. sports), seven Mandarin Ducks (Ar. sperins), deven Mandarin Ducks (Ar. sperins), bred present the China Ducks (Arms. sportshool), a Spotted-luide Ducks (Arms. sportshool), a Spotted-luide Duck (John Anaton Aynchin), bred in Carlos (Montrole Montrole Montrole

OUR ASTRONOMICAL COLUMN.

THI. SIRLIAR CLIP-11 Ry PERFI — Mr. O. A. L. Phil has completed a mixmourner examination, beguin in 1870, of the group x of the great star cluster in ferencia, and the results are group x of the great star cluster in ferencia, and the results are classes all stars down to 10 fanginuties, and a number of fainter once down to 117 magnitudes, the total number of stars resulted hering 250. The postorion obtained, joined to those the claster. Frov Vogel has determined the postness of 178 stars in the central part of the x group, but Mr Pihl's investigation of 178 stars in the central part of the x group, but Mr Pihl's investigation of 178 stars in the central part of the x group, but Mr Pihl's investigation of 178 stars in the central part of the x group, but Mr Pihl's investigation of 178 stars in the central part of the x group, but Mr Pihl's investigation of the x group in the composition of the x group in the central part of the x group, but Mr Pihl's investigation of the x group in the x group in

A ring and a bar micrometer were used in the observations, and the reductions were made by the ordinary method of taking half the sum of the moments of lingress and egress in the calculation—a goode of proceeding which depends upon the supposition that the half sum denotes the matent of the passage of

the star through the middle of the ring or bar. This supposs-Use star through the middle of the ring or bar. In its supposa-tion, however, is shown to be erroncoss. For stars of a less magnitude than 5'5 there is always a detention in the apparent tune of emerion, which increases with the faintness of the star observed. The cause of the error, therefore, is physiological, and due to the occaling micrometers employed. The law rega-lating it having been found, the necessary corrections have been applied to the measures, thus rendering the work of greater

use. The memoir represents the work of a business man over a period of twenty years, and with an instrument having an aper-ture of 31 loches. It contains much of interest, and will doubt-less be appreciated as an important contribution to the know-tick and the stars in a cluster which is certainly one of the grandest of telescopic objects

SOCIETIES AND ACADEMIES.

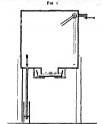

Royal Society, June 18.—"An Apparatus for testing the Secutiveness of Sately-lamps." By Frank Clowes, D.Sc. Lond, Professor of Chemistry, University College, Nottingham. Communicated by Prof. Armstrong, F.K. S.
The following apparatus has been deviced to render easy the

NO. 1133, VOL. 44]

process of testing the sensitiveness of different forms of safety-lamps when used for detecting firedamp. To enable satisfactory test to be made in the laboratory, it was necessary to insure (1) the easy and rapid production of mistures of firedamp and artificially prepared in enhance, which preparented form of the (3) to examine the flame of the lamp under conditions as satisfactory as those estable; in the mine. A wooden cubical box of about too litree capacity was contracted to as to be as nearly gas-tiph as a possible. It was contracted to as to be as nearly gas-tiph as a possible. It was paraffin wax, which was afterwards caused to penetrate more prefectly by passing an ordinary bot flations over the surface.

perfectly by passing an ordinary hot flat-iron over the surface.

This testing chamber was furnished with a small inlet tube at the top, and with a similar outlet tube below. It had a plate-glass window in front for observing the lamp in the interior, and a fianged opening below for introducing the safety-lamp. This pocching was closed by a water-seal consisting of a small zinc opening was closed by a water-seal consisting of a small sine try supported by hattons, and containing about a inches depth of water, into which the flagge dopped. A mixer was arranged, to the section of the chamber, and suspended by a dimensional to the section of the chamber, and suspended by an employ backwards and forwards from the side to the top of the interior of the chamber, by grasping a handle projecting through the bone of the databers, which are a formal properties of the thouse of the databers.

F10 -

When a mixture of air with a certain definite precentage of

finedamp was required, the methons, prepared and purified by ordinary chemical methods, was introduced into the chamber in the requisite quantity by the top index. It displaced an equal volume of air, which escaped through the lower outlet, the exit end of which was scaled by being immersed just beneath a water sprace. A vigorous use of the mixer secured, a uniform maxture surface. A vagorous use of the sainer securids a uniform anxieve and of gas and as throughout the interior of the chamber in the course of a few seconds. The lamp wes then introduced into the chamber, and placed in position behind the glass much discussion of the chamber and placed in position behind the glass midd the necessary opening of the chamber very bord, and the introduced into and removal of the lamp many times in succession was not found to produce any approcable effect upon the composition of found to produce any approcable effect upon the composition of as the cap underwent no further change. A lamp was left dimensions of the "cap" over the finne were noted as soon as the cap underwent no further change. A lamp was left burning in the chamber for a considerable length of time, and of the chamber and the very limited amount of sir required to support the combistion of the unifi flame always used in gastesing. The whole sittener of the chamber and murer were against a black ground. against a black ground.

sganata black ground.
The methane was introduced from an ordinary gas-holder.
The methane was introduced from an ordinary gas-holder,
was poured into the top of the gas-holder. The gas-tap of the
holder was then momentarily opened, so as to produce equilibrium of pressure between the methane and the simosphere
upper niels of the chamber, the water tap was opened, and the

measured volume of water was allowed to flow down and drive the
measured volume of water was allowed to flow down and the water was allowed to flow down and the water water was allowed to flow down methane into the cnamuer As soon as ouncies or air ceased to appear through the water at the outlet, the chamber was closed, the mixer was then vigorously worked for a few seconds, and the mixture of gas and air was ready for the introduction of the lamp. Before introducing the methane for a fresh mixture, the atmosphere of the chamber was replaced by fresh air by restantially the contraction of the chamber was replaced by fresh air by removing the water-tray from beneath the opening at the bottom of the chamber, and blowing in a powerful stream of air from a bellows to the top of the chamber

The chamber was supported on legs, which were arranged so as to place it at a convenient height for observations through the window, and also for the introduction and removal of the safety-

The observations were usually made in a darkened room, but the flame-caps were easily seen in a lighted room, provided direct

light falling on the eye or chamber was avoided

The capacity of the chamber was 95,220 c c, accordingly, the following volumes of methane were introduced for 2 per cent instruct 476 cc, for 1 per cent 1952 cc, for 2 per cent.

1904 co., for 3 per cent 2856 cc, for 4 per cent 3808 cc, and for 5 per cent. 4760 cc It will be seen that a sense of tests, in which the above-mentioned percentage mixtures were employed, involves an expenditure of only 15 litres of methane, a quantity far smaller than that required by any other method of testing as yet described

iceting as yet described.

Of many form of safety-lamp tested in the above apparatus, the one which most satisfactorily liftilled the two purposes of effectent illumnation and deletory in gas-testing was at dword's construction, burns bemoine from a sponge reservoir, and its fame is surrounded with a plass optioner, which is ground rough at the hinder part, this latter device prevents the numerous reflected images of the flame, and the generally dilitied reflections which are seen from a smooth glass surface, and which reduce the contraction of a small pale flame approximation. If not impossible.

If not impossible.

The wick of this lamp, when at a normal height, furnishes a fame of great illumnating power. When lowered by a fine serw adjustence the finns becomes bine and non-luminous, serw adjustence the finns becomes bine and non-luminous, which fully bear out the unusual sensitiveness of this finne. With 0.3 per cent. of methane 7 mm.; with 1 per cent. for the finns of the finns of

NO. 1133, VOL. 44]

It appears from the above record of tests that the problem of producing a lamp which shall serve both for efficient illuminating and for delicate gas-testing purposes has been solved. The solu-tion is in some measure due to the substitution of benzoline for oil, since the flame of an oil lamp cannot be altogether deprived of its yellow luminous tip, without serious risk of total extinc-tion, and this faint luminosity is sufficient to prevent pale caps from being seep.

261

From further experiments made in the above testing-chamber with flames produced by alcohol and by hydrogen, it was found to be true in practice, as might be inferred from theory, that, if the flame was pale and practically non-luminous, the size and definition of the flame-cap was augmented by increasing either the size or the temperature of the flame. It is quite possible by edefinition of the finan-cap was augmented by increasing other the size or the temperature of the flame. It is quite possible by attending to these conditions to obtain a flame which, although statement of the conditions to obtain a flame which, although a ball for the measurement of any proportion of gas exceeding; 3 per cent. This must, for the general purposes of the miner, be looked upon as a defect; but it so not a fault of the lamp already referred to. It is of interest to note that with the Pieter spiri-tuage a flame-cap at much in height was seen in au recontaining only 0'5 per cent, of methane

Physical Society, June 26 — Prof. W. E. Ayrico, F. R. S. President, in the chair — The following communications were made — The construction of non-inductive resistances, by Prof. W. E. Ayrico, F. R. S., and M. T. Mahler. In making some transformer tests about three years ago, the authors had occasion to consider the construction of electric conductors the impedto consider the construction of electrix, conductors the impediance of which should be princtically equal to their resistances. This conduito could only be fulfilled by making the inductance mail in comparison with the resistance, and, as the former mail in comparison to the conductor of the former was important to use substances of high specific resistance. Carbon or plasmod being available, the latter was chosen on account of its low temperature coefficient. One form of resistance exhibited consisted of strips of this sheet platmoid about 6 metres long and 4 centimetres with Each was been at the middle and doublet bed, on itself, this tall being and the middle and doublet bed, on itself, this tall being placed between the contiguous parts and narrow ribbon used to bind the parts together. Twelve such strips arranged in series had a resistance of 2'95 ohms, and would carry a current of 15 amperes without changing its resistance more than 15 per cent. This strip-resistance was made by Messrs C G Lamb and E W Smith, who at that time (1888) were students in the Central Institution, and to whom the author's best thanks are due for Institution, and to whom the author's best thanks are due for the pranseous thym manner in which they surmounted the difficulties which present the properties of the properti as assets on permoutirs appointents that the bending moment is proportional to the curvature, the author pointed out that this assumes that the cross-sections remain plane after flexure, and neglects the surface loading effect. The present paper describes experiments made to determine the actual state of strain in a beam doubly supported, and carrying a single load at the centre, the effect of surface loading being taken into account. The the effect of surface loading being taken into account. The method of investigation assumes that (1) the true state of strain at the centre of a beam may be found by superposing on the state of strain due to bending only, that due to surface loading without bending; (2) the state of strain due to surface loading palacements of the state of strain due to surface loading. only, may be found with close approximation to ruth by resting the beam on a flat plane instead of on two supports; (3) the strain due to bending alone, may be obtained from the Bernoulli-Saint-Venant results. Before proceeding to describe Bemoniii-Sant-Venant result telore proceening to oescribe the experiments, a short account of the mathematical work previously done on the subject was given. The nearest approach to the particular case here dealt with had been worked out by Prof. Bousslassed, who had shown that for an infinite elastic solid bounded on one side by a plane surface and loaded along a line on that surface, the stress (y) on an element on the normal through the middle point of the line varies inversely as its distance (x) from the surface. The formula thus arrived at was $y = 0.04 \frac{P}{x}$, whilst for a finite beam centrally loaded the

author's experiments gave $y = 0.726 \frac{P}{r}$. The experiments were made on glass beams mounted in a steel strinking frame, and placed between the crossed Nicola of a polarizope. Steel collera a mu. of the place of the collection of the collection of the beam were measured by a micrometer's cross at point opposition of the beam were measured by a micrometer screw at a point opposition the central load, and traversing provise of the whole frame to be moved so as to bring any portion of the beam in the field of view. Circularly polarized light was somewhat the collection of beam in the field of view. Circularly polarized light was some times used, and a micromater yeprotoc served to measure the distances between interference fringes produced by loading. By carefully chosen experiments the author had shown that if a beam of less as the second of the second of the second of the term of the second of the second of the second of the second of contact of the load is inversely proportional to the point of contact of the load is inversely proportional to the distance from the point of contact. In the first experiment the ownwell Nicols were set at 4g to the axis of the loaded bar, a quarter-wave plate was then placed between the bar and the analyzer, and the position of the black gots at the point where the effect of the shear on the polarized light was equal and opposite to that protimes by in requirements plate when noted by a second on proven the province of the first point on the first, is the black spot moved upwards to a point where the shear was double that at the first postulor. This position having been determined, one quaren-wave plate was removed, and the load dismoushed until the original spot moved up to the second position, and until the original spot moved up to the second position, and which the shears were in the proportions 1, 2, 4, 8, 8c., were determined. Flotting the results showed the curve connecting the shear and the distance from the point of contact to be hyperbolic. Other experiments showed that the shear at any point and measuring the distance between the interference fringer below the point of contact the hyperbolic law was confirmed. duced by the quarter-wave plate was noted. A second quarterand measuring the distances between the intersections tringer below the point of contact the hyperholic law was confirmed. The effect of bending a beam is, according to hypothesis, to put the upper portion in longitudinal compression, and the shear the upper portion in longitudinal compression, and the snear (vertical stretch) varies as the distance from the centre of the beam; the shear due to surface loading is a vertical squeeze, and, as shown above, varies hyperbolically When, there fore, the beam is subjected to both actions, the straight line presenting the bending strain may intersect the hyper-la representing the shear due to surface loading in two bola repres points, and since, at the corresponding points in the central section, the shears are equal and opposite, the elements are only subjected to voluminal compression, and will exert no bi-refringent action. Hence, when viewed through crossed Nicols, black spots will be seen on a white field Keeping the lead constant and diminishing the span should cause the spots to approach each other, and when the line is tangential to the hyperbola, the spots coincide These deductions were conhyperbola, the spots coincide. These detuctions were confirmed by experiment, and it was found that for a span of less than four depths, no point of zero shear exists on the central section The strain in beams subjected to surface loading were this shown to be of a character different from those usually assumed, the neutral axis instead of coinciding with the axis of assumed, the neutral and instead of concerning with the axis of the beam, being lifted up in the centre, and its shape-depending on the load and span. Other ingenious and unteresting experiments on beams were described, in some of which the lines of principal stress were mapped out. Remarkable results were obtained, showing that although the tension lines given by Rankine and Airy are nearly correct, the curves of compression may be very different, and have very curious shapes Prof. Perry thought the local loading effect would not be so important Perry thought the local loading enect would not us so important in long beams, and inquired whether in ordinary test pinces local loading would affect the breaking strength. He also asked what effect the fact of the load making contact over a surface instead of along a line would have on the results, and in repty Prof. Carus. Wilson saul the effect was to raise the asymptote of the hyperbola representing the surface loading stress above the surface of the beam —On pocket electrometers, by C V Boys, F R.S. This communication described modifications of electrore K.S. Into communication describes monatons of electro-meters adapted for portability. As quarts fibres increases the delicacy and diminish the disturbing influences affecting instra-ments, much smaller controlling forces can be employed than when silk is used for supersinons. He had, he said, pointed out some time ago the great advantages arising from making

galvanometers small. Applying similar reasoning to electro-meters, he remarked that making an instrument one-tenth the size of an existing one reduced the moment of inertia of the needle to I whilst the deflecting couple for given potentials would only be 1/2 of its former value. The small instrument would for the same periodic time be 10,000 times more sensitive than the large one, provided the distarbing influence could be would for the same periodic time be 10,000 times more sensulvish than the large one, provided the distarting milaners could be to distarting milaners could be to ordinarily possible, for any method of making contact with the meedle, such as by a fine were dispoling into seld of or mercary, prevented very small controlling forces being used. Sill, type stands develors a large proportion of the fill advantage could tack was essential to success. The first instrument described was one in which the needle was cynindrasl, contiguous quarters being insulated and connected to the opposite ends of a minute the medium of the control of t potentials. This bold experiment proved remarkably successful, for the instrument was very sensitive A disk shaped needle for the martument was very sensitive A dask shaped needle with quadrants, stlematedy sinc and platium, was then employed, and by this a small fraction of a voit could be measured, as the control of the could be measured as the could be turned used to down or carried shout in the pocket with impunity. Another small instrument with the stitutionary quadrants of irms and copper was exhibited, and by rotating them through an angle to you to as to bring the country of the stons relating to ballistic electronieters and electrosistic Stemens dynanometers, and pointed out the possibility of instruments such as he bad exhibited being of use in elucidating the obscure points in connection with so-called "contact electri-city." The President complimented Mr. Boys on the beautifully simple and remarkably sensitive electrometers exhibited. He simple and lengthany sensitive electroneers enforced. He remembered that some years ago Mr Gordon made a very small electrometer, but its insulation was insufficient for electrostatic work He agreed with Mr Boys as to the advantages of small instruments, providing sparking across or tilting of the needle could be prevented On the other hand, he thought the use of small potential differences on the needle was a step in the use of small potential differences on the needle was a step in the wrong direction, when great sensability was required. Prof. Ferry asked if the needle could not be kept changed by Coccasional contacts with a changed and cup. Mr. Boys and he had not yet done so. It is also suggested that an electrometer of very small capacity might be made by reducing the quadrants surrounding a dusk-needle, until they became like small tuning-forks—A paper on electrifaction due to the contact of gases with lequids, by Mr. J Enright, and one on the expansion of chosine by feed, by Dr. Arthur Richardson, were taken as

THE TEACHING OF FORESTRY

A Manual of Forestry By William Schlich, C.I.E., Ph.D. Vol II (London Bradbury, Agnew, and Co, 1889.)

N a loop of the Main river in Lower Franconia, east of Aschaffenburg, rises an extensive mountainous country, clothed with almost unbroken forest of singular beauty and of enormous value. It is the Spessart, in old times known as the home and haunt of great highway robbers, but also known from time immemorial as the home of the best oak timber in Germany The red sandstone of the Trias, which everywaere is the underlying rock in this extensive forest country, makes a light sandy loam, which, where deep, is capable of producing tall, cylindrical, wellshaped stems Having grown up, while young, in a densely crowded wood, the oak here has cleared itself of side branches at an early age Hence these clean straight stems, which in the case of spruce, silver fir, and other forest trees, may justly be said to be the rule, but which the oak does not produce, save under these and similarly. favourable circumstances The species here is Quercus sessibiliona, this species does not form pure forests, but is always found mixed with other trees, the hornbeam, the beech, and on the lower slopes of the western Schwarzwald, the silver fir In the Spessart, the beech is associated with the oak, in the same manner as the bamboo is the chief associate of the teak tree in Burma.

In publishing his manual of forestry, the author wished in the first instance to place in the hands of the students at the Coopers Hill Forest School a handbook to facilitate their studies That Forest School was. tt may be remembered, established in 1885, in connection with the Royal Indian Engineering College at the same place, in order to give the needful professional training to young Englishmen who desired to enter the Indian Forest Department. Accordingly, when the first volume of that manual appeared in 1889, it was natural that some, who took a strong interest in the progress of forest management in the British Indian Empire, were surprised that the book did not deal with Indian trees, and that its teaching related to the oak, the beech, the Scotch pine, and other trees of Europe. By some of these zealous friends of Indian forestry the book was pronounced a failure, because it did not treat of Indian forest trees

The principles which guide the forester in the proper treatment of his woods are the same all over the world, in India as well as in Europe. But while the application of these principles to the treatment of Indian forests is not more than thirty-five years old, the methodical and systematic treatment of European forests is of old standing, and has stood the test of experience. In the teak forests of Eurina, the bamboo has a position similar to that of the beech in the oak forests of the Spessart. Oak and teak are both trees with comparatively light foliage. Pure woods of these species, while young, are sufficiently dense to shade the ground, whereas at an advanced age the wood get their, the canopy light, and the results is that

grass and weeds appear, and that by the action of sun and wind the soil hardens and is less fertile than the loose porous soil, which is shaded by dense masses of foliage. Hence the advantage of associates, which, like the beech in Europe and the bamboo in Burma, shade the ground with their dense foliage and enrich it by the abundant fall of their leaves. But it is not only the condition of the ground which is improved by these useful associates. Teak and oak have this specialty also in common, that, when growing up alone, their stems, instead of running up into clean cylindrical boles, are apt to throw out side branches. which greatly impair the market value of the log. But when growing up in dense masses with their natural associates, these latter, crowding in as they do on all sides, around the oak in the Spessart and the teak in Burma, prevent the development of side branches and thus produce clean and regularly shaped stems

In these and many other ways are the associates of the teak and of the oak useful friends, so to speak. Under certain circumstances, however, and at certain periods of their life, they are dangerous enemies to their more valuable companions On the sandstone of the Spessart and elsewhere, the beech, as a rule, has a more vigorous growth than the oak; it gets the upper hand, and, unless it is cut back or thinned out in time, the oak, if both are growing up in an even mixture, has no chance The bamboo is even more formidable as an enemy of the young teak tree. Though the teak may have had a long start : if a crop of bamboos-either the shoots of old rhizomes, or perhaps the result of general seeding of the old bamboo forest, cleared away to make room for the teak-springs up among it, the teak is doomed. As soon as the rhizomes of the bamboo have acquired sufficient strength, they produce, within a few weeks, during the rains, such a profusion of full-sized shoots, say 20 to 30 feet high, that the young teak trees among them are throttled and extinguished.

The similarity in the relations of teak and bamboo in Burma, and of oak and beech in the Spessart, has led foresters in both countries to devise similar arrangements for the regeneration of these forests. In the Spessart, when the old timber in a compartment of the forest is cut, the best places for the growth of the oak are selected, and the oak, which here sells at the rate of from 2s, to 3s, a cubic foot for sound and well-shaped pieces, is sown on soil most suitable for its development; while the beech, the timber of which only fetches about one-fifth of that amount, is allowed to reproduce naturally from self-sown seedlings over the rest of the area. Among the oak also a certain but small proportion of beech springs up, and even where pure oak woods may be the result of these proceedings, it will not be difficult, when they are sufficiently advanced, to introduce such a proportion of beech as will secure their satisfactory development. In the same way in Burma, selected areas are cleared for the growth of teak in the original forest, the clearance being effected and the teak planted with the aid of that rude mode of shifting cultivation, known as the Toungya system.

Many other instances might be quoted, in which similar practices have developed in the rearing and tending of woods in Europe and in India. The principles of sylviculture are the same everywhere, and the application of these principles to the treatment of woods in different

^{&#}x27;See NATURE, vol zli p 121

parts of the globe has, in many instances, led to the adoption of similar methods: hence Dr Schlich was right in selecting the timber trees of Europe to illustrate the application of these principles in the manual before us.

Sylviculture, the author explains, is the formation and tending of woods, and he divides his subject into four chapters. The first of these chapters treats of preliminary works, such as choice of species, fencing and reclamation of the soil by draining, the fixation of shifting sands, the breaking through of an impermeable substratum (pan) and the like In regard to the fixation of shifting sands. an interesting account is given on p. 33 of the methods which have been most successfully practised on the west coast of France, in order to stop the progress inland of the coast dunes, and to clothe these ridges of rolling sand with a productive forest of the cluster pine (Pinus Pinaster) A belt, in many places five miles wide, along the coast of Gascony, and considerably further north, has in this manner been reclaimed, and the steady progress of the sand, which had covered large areas of fields and meadows, and which had destroyed numerous villages, has thus been arrested

Chapter ii deals with the formation of woods by artificial and natural means. The Spessart, which has been mentioned above, is an instance in which both artificial and natural means are used in order to effect the regeneration of the forest, so as to insure the production of timber of the highest possible commercial value. In most large forest districts on the continent of Europe, both the natural and artificial method are employed As the author says on p 178, neither the one nor the other system "is the best at all times and under any circumstances; only a consideration of the local conditions can lead to a sound decision as to which is preferable in a given case" In France, for instance, a country highly favoured by a climate uniformly moist and mild, where most forest trees produce seed more frequently than in Germany, natural reproduction may, broadly speaking, be said to be the rule and planting the exception But in France, also, planting operations on a large scale have been carried out on the dunes of the west coast as well as on bare mountain-sides of the Alps. the Cevennes, and the Pyrenees, and, wherever necessary, planting is resorted to, to supplement the natural regeneration of the forests

An instance in which over a large extent of country the forests are regenerated artificially may be found in the State forests of the kingdom of Saxony, together with most of the communal and many of the private forests in that country. The State forests of Saxony cover an area of 432,000 acres, and by far the larger portion of this area is stocked with pure spruce forest treated on a short rotation of eighty years, and regenerated artificially by planting The high prices realized in this industrious and thickly populated country, even for timber of small sizes, have gradually led to the adoption of this system; and the State forests of the kingdom of Saxony are a pattern of methodical and most successful management. The forest ranges, all in charge of highly trained superior forest officers, are small, containing not more than 2000 to 3000 acres each, and many of these ranges have a steady regular annual yield of 140 cubic feet of timber per acre, and for foresters proceeding to India. For in that large

and local of 100 marks per hectare, which corresponds to forty shillings an acre

But in Great Britain also, and in Scotland especially, is the system of rearing forests by planting well understood. and it is practised over large areas economically and successfully. French as well as German foresters of great practical experience have repeatedly expressed their high sense of the skill and ability with which large plantations are formed in Great Britain at a comparatively moderate cost. But even foresters and wood-managers in Great Britain may learn a good deal from this portion of Dr. Schlich's book Their attention might specially be directed to the author's remarks on p 113, regarding transplants which have developed a lopsided root system, "because the trenches, into which the pricked out seedlings are placed, are often made so shallow, that the root system of the plants, instead of assuming a natural position in the ground, is altogether bent to one side."

That section of the second chapter which deals with the natural regeneration of woods, necessarily divides itself into two portions first, natural regeneration by seed; and second, by shoots and suckers (pollards and coppice). Concise brevity is one of the great merits of Dr Schlich's manual, and it doubtless was necessary to curtail, and to make a rigid selection of the most important matters. But the treatment of coppice woods and of coppice under standards might perhaps have been a little less brief.

As regards natural regeneration by seed, the Black Forest in South-Western Germany may be quoted as an instance where, over extensive areas, the forest is chiefly regenerated by natural means. The splendid logs of spruce and silver fir, which are floated down the Rhine in numberless huge rafts, have all grown from self-sown seedlings. and most of the young timber now growing up has had the same origin The timber which is brought to market from these forests is much older and heavier than that sold in the forests of Saxony, but the results of management are to some extent similar. There are some forest ranges in the Schwarzwald, both in the grand-duchy of Baden and in the kingdom of Wurttemberg, which yield the same annual quantity of timber per acre, and furnish the same rate of net revenue to their proprietors, as those of Saxony. The term of rotation, of course, is much longer, and the system of natural reproduction takes time, hence the money value of the growing stock of old timber is very large, much larger per acre than in Saxony. The interest, therefore, on the capital invested (value of land plus growing crop) is less in this case. The discussion of these matters, however, does not appertain to sylviculture, but to forest management, with which the author will deal in a subsequent volume of his work.

As already mentioned, in France the natural regeneration of forests is the rule, chiefly owing to its wonderfully favourable climate. Large areas, mainly of private and communal forest, are managed in admirable style, as coppice woods and as coppice under standards. The treatment of high timber forests also, and their regeneration from self-sown seedlings, by means of a regular system of successive cuttings, has in France been brought to a high state of perfection. This circumstance renders the French forests specially valuable as a field of instruction furnish a net revenue, after deducting all charges, general | country, though planting has been commenced and must

necessarily be carried on in some instances on a large scale, yet every effort ought to be made to develop good systems of natural regeneration in the different provinces

On pp. 132-64 the author gives a clear account of the different systems which have in course of time been devised, in order to effect the natural regeneration of woods by seed Under the more favourable climate of France the desired object is generally effected by a simple and to some extent uniform system of successive cuttings In Germany, on the other hand, where droughts are frequent, frosts severe, and where good seed years generally are of rare occurrence, the system of regular successive cuttings, which originated in Germany, in many cases was found to fail, and accordingly, some sixty or seventy years ago, the tide set in in favour of artificial reproduction A reaction, however, has for good reasons taken place in many parts of the country, and during the last thirty years German foresters have been busy in adapting the system of natural regeneration to the peculiar conditions of each forest district. Indian forest students should go to France, in order to become impressed with the fact that under favourable circumstances natural regeneration of high forests may be effected by a simple and easy system of treatment ln German forests, on the other hand, they should learn how the difficulties of a climate frequently unfavourable have been successfully overcome by devising systems of treatment suitable to the requirements of each locality, and the knowledge here acquired will be most useful, nay, necessary, to them in India, where the conditions of climate by no means always favour the natural regeneration of the more valuable forest trees

Space forbids a full discussion of this most important and interesting subject. This portion of Di, Schlich's book, if supplemented by the study of forests on a large scale, particularly in Germiny, will be most useful to foresters who may be called upon to devise methods of forest treatment in other parts of the globe, be it India, Australia, South Africa, or North America.

Closely allied to the subject just adverted to is what the author says in the fourth section of the same chapter regarding the formation of mixed woods. Pure woods, consisting of one species only, are exposed to various risks, from which mixed woods are exempt. Hence, in most Continental forests, there has of late years been a strong tendency in the direction of favouring the growth of mixed woods, such as oak and beech, oak and hornbeam, oak and silver fir, Scotch pine and beech, and the like. It goes without saying, that operations in this direction, in order to be successful, must be guided by careful study of the mode of growth and of the peculiar requirements of the different species in different places and under different conditions. Something has been said above regarding the treatment of mixed woods of oak and beech in the Spessart. But it does not follow that oak and beech behave in the same manner everywhere. On certain kinds of shale, belonging to the Devonian formation, for instance, the oak rather than the beech has the tendency to take the lead, and here mixed woods of oak and beech can be produced from self-sown seedlings much more easily than would be possible on the sandstone of the Spessart. Again, along the foot of the Western Schwarzwald, where, as already stated, the

silver fir is associated with the oak, this tree, though a shade-bearer like the beech, renders it much easier for the oak to hold its own in an even-aged mixed wood, because in its early youth it grows very slowly, thus gring the oak a good start in life

Chapter II teaches how woods should be tended during carly youth and afterwards Passing over what the author says regarding cleaning of young woods and pruning, we come to thinning operations. On p. 200 an interesting statement is given showing the number of trees per acre in certain mixed woods of the 5chwarzwald. The figures are as follows.

Thus, during the life of a wood, and this holds good in all cases, the number of trees per acre decreases gradually from several thousand to a comparatively small number at maturity When, as usual, the object is to produce high class timber, with clean well-shapen stems, the rule 15, as the author correctly states it. " The wood should be thinned lightly until towards the end of the principal height growth, then the thinnings should gradually become heavier, so as to assist a selected number of trees by the gradual removal of all those which are inferior and diseased" In its youth the wood is crowded, the young trees maintaining a severe struggle for existence. The weaker trees are suppressed and some are actually killed, while the rest are either dominant trees, with their head well above the others, or dominated, though not suppressed Formerlythinnings were generally done by rule of thumb, the dead, oppressed, and a portion of the dominated trees being removed. But it is obvious that, when the object is to produce valuable timber. thinnings must so be managed, that the trees which are destined to attain the term of rotation, and which will form the final crop to be cut down, in the example here given, 262 trees per acre 100 years old, shall be sound and regularly shaped. It is obvious that to attain this object dominant trees also may occasionally have to be removed, if unsound, spreading, or irregular shaped, and this is properly recognized by the author. He justly adds that in such cases dominated and even suppressed trees may have to be spared in order to keep the ground well under cover. Such would he the practice in the case of woods consisting of one species only, or of several species of equal value Where one species, such as oak or teak, is of much greater value than the others, all thinnings must, as a matter of course, be so arranged as to favour this species at the expense of the rest

So far concerning the thinning of crowded woods. The last section of the same chapter deals with the tending of open woods for the production of large timber Into this subject, which is one of some difficulty, though of great importance, it would lead too far to enter on the present occasion.

Chapter 1v. contains sylvicultural notes on British forest trees, with notes (by Prof. H. Marshall Ward) on botanical characters serving to distinguish the principal British forest trees. The two species of oak dealt with in

the sylvicultural notes are Ouercus pedunculata and Overcus sessilutora. Botanists are well aware that the maintenance of distinctive characters between these two and others of the European species of Quercus is difficult, so much so, that the best authorities on English trees have decided to re-establish the old species of Linnæus, Quercus Robur, and to regard the two species named merely as forms or varieties. The forester has a different task, and for him the mode of growth and the requirements of these two oaks are so different that he must keep them separate. It will suffice to mention one point, which has not perhaps been brought out sufficiently by the author The mixed woods in which Quercus sessiliflora is associated with the beech, the hornbeam, and the silver fir have been mentioned above. In natural high forests this species is only found in company with other trees, and particularly with the three kinds named. The pure or nearly pure coppice woods of Quercus sesuliflora in France and Western Germany are an exception, these, however, have been converted into pure woods by the longcontinued cutting out of beech, hornbeam, and soft woods. Ouercus pedunculata, on the other hand, does form pure high timber forests of considerable extent Such are found both in Northern and Southern Europe. not on hilly ground, but always on deep alluvial soil. Instances are the forests on low ground along the Elbe and other rivers of North Germany, the magnificent pure forests of that tree on the banks of the Adour river near Dax in Gascony, and similar ones in the peninsula of Istria, south of Trieste There is underwood on the ground in the forests named, but it merely consists of thorns and low shrubs. The two species, Ouercus sessiliflora and pedunculata have different requirements and require somewhat different treatment. This, however, is a small matter These sylvicultural notes are most valuable, and it is satisfactory that the Weymouth pine and the Douglas fir have been included among them.

The second volume of Dr. Schlich's manual, like the first, will be an immense help to the students who are trained at the Coopers Hill College for forest service in India. It will be a great bono to all who are charged with the management of forests in India, in the colonies, and in the United States of North America. And it may perhaps be hoped that in Great Britain also this excellent book will in course of time tend to awake an ome general interest in the good management of its woodlands, which are very extensive, and which some day may be of considerable importance and of great value to their proprietors.

D BRADISS.

THE APPLICATIONS OF MODERN CHEMISTRY,

Dictionary of Applied Chemistry. Vol. 11 (Eau-Nux). (London: Longmans, 1891.)

THE editor of a dictionary of applied science, such as the volume before me, has in these days no envisible task to perform: much is required of him, and the difficulties with which he has to contend are great. Prof.

NO. 1134, VOL. 44]

Thorne has acquitted himself well, for though there may be, indeed there are, many points with which the expert can find fault, yet these are generally matters of detail. and on the whole the work has been satisfactorily done. so that the second volume will be found to be quite up to the high level of the first. The industries which owe their foundation to the science of chemistry now progress with such grant strides, that processes which last year were the newest and best may this year be so improved as to be rendered obsolete, so that an article printed at the commencement of a volume may become antiquated before the last article is in type, whilst data unattainable when the article was written are superseded by some more recently published. As an example of this, I may take that upon "gas coal," written by a most competent authority, Mr Lewis Wright. On p. 177 will be found a table giving the weight of coal carbonized by all the authorized gas undertakings in the kingdom, exclusive of those of local authorities, for the year ending March 25, 1886 Since these tables were printed, a Board of Trade return for 1890 has been published In 1886, 8,378,904 tons of coal were carbonized; in 1890 the figure rose to 9,663,011 In 1886 the mileage of mains was 18,967, in 1890 it had increased to 21,584. These numbers point out the enormous extent of the coal-gas industry in this country, and show clearly that it is not suffering from the competition of electric lighting . indeed, this competition is favourable to the sale of gas, for we see that our streets are now better lighted than formerly, and the consumption of gas in many shops is increased, in order to vie with the splendour of their neighbours' electric light.

As a critic is bound to criticize, I may point out some few faults of commission and omission which have struck me in reading through this generally excellent article

The important steps which have recently been taken in many large works for charging and drawing the gas retorts by mechanical means are barely referred to. Great economy is doubtless effected where such laboursaving mechanical appliances have been adopted, and a description of these would have been of interest, as the labour agitation in our gas-works has brought engineers face to face with this question. Another point upon which a statement would have been of value is the most improved arrangements of the purifying house, and the methods adopted for charging and discharging the purifiers That " the whole of the sulphuretted hydrogen, carbonic acid, and carbon disulphide can be easily and economically removed" (p 200) by a combined system of oxide and lime, and with a proper arrangement of purifiers, is a statement to which many gas engineers will demur The London companies, especially, who have a legal standard limit for sulphur compounds, find it both difficult and expensive to keep down the impurities to the necessary point. The illustrations given in this article are scarcely worthy of the letter-press. Figs. 22 and 23 do not give an idea of the construction of a modern gas-holder, some of which now have the enormous capacity of ten million cubic feet, and are marvels of engineering skill. A description of the latest improvements would have added interest to the article.

As an instance of the rapid progress of an industry interfering with an adequate account being published in the early pages of such a volume, I may refer to the article on electro-plating, by Prof W. C. Williams, which, although giving a clear account of the older processes scarcely represents the position of to-day. Thus no reference is found to recent methods of the electro-deposition of metals, as, for example, the Elmore copper process, or to that of plating by alumnium in or does any mention occur of the electric power suitable or used for depositing metals.

To justify the opinion that this volume is no unworthy successor to that published last year. I would refer to a few articles which are certainly the best I know on their several subjects First, "Explosives," by W. H. Deering. coming from the pen of one who has had long experience in the Chemical Department of the Royal Arsenal, Woolwich, is, as we should expect, up to the level of the time. and in every respect excellent Second comes Prof. Percy Frankland's article on fermentation. No one is more competent than he to write on this most fascinating subject, and his article reads like a novel, and even better. for "truth is stranger than fiction", and Percy Frankland tells his story so clearly and well that I will not spoil the pleasure of his readers-and they ought to be many -by any attempt to abstract its results Thirdly, the article on "Matches," by Mr. Clayton, may be cited as an admirable treatise on this important branch of chemical manufacture, condensed into 24 pages. Not the least important contribution are the nine tables giving. in chronological order, lists of the numerous patented and other inventions in this department of chemical technology Lastly, I will select Mr Wynne's exhaustive article on naphthalene as perhaps the most able and valuable in the whole volume. When we learn that, although it occupies 65 pages of the dictionary, it treats exclusively of the derivatives of one hydrocarbon, and only of those of them which are now used in the arts. and valuable for industrial purposes, we begin to form an idea of the extent and importance of the results of modern organic research, which has opened out regions illimitable, leading to practical results such as the chemists of the last generation would have deemed impossible.

In a dictionary of applied science the question of selections seven more difficult than in a similar work of pure science. Here the knowledge and lact of the editor are especially called into play. Prof. Thorpe has, I think, thosen well, but here and there some pages are taken up with matters of which I should be glad to learn the present industrial value—for in the future all may have a use. Thus I find close together the following: eladic acid, ericolin, reuce acid, erythor—lall, doubless, compounds of scientific interest, but hardly, I would venture to suggest, of industrial importance.

As I said of the first volume, so I may say of the second—that it does credit to the authors of the articles, to the editor, and to the public-spirited publishers. It is good that English scientific literature keeps up its pressige for thoroughness, clearness, and conciseness, and that in this volume of the dictionary no falling off from this standard is visible. H. E. ROSCOE

NO. 1134, VOL. 44

THE FISHES OF SWITZERLAND.

Faune des Vertibrés de la Suisse Par Victor Fatio. Vol V. "Histoire naturelle des Poissons." 2me partie, avec 4 planches, pp. 576 Supplémens, pp. 13. (Genève et Bale H Georg, 1890)

A S more than eight years have elapsed since the publication of the last volume of the "Faune des Vertébrés de la Suisse," I may preface this notice with a few words as to the general scope and progress of this important work. The first volume, published in the year 1859, was devoted to a detailed account of the Mammais of Switzerfand; the third (1872) to the Reptiles and Batrachians, and the fourth (1882) to a part of the Fishes (Acanthotery gians and Cyprinoids), the second volume, which will contain the Birds, being still in course of preparation

The part now published, which is the fifth of the series, treats of the remaining half of the fishes, notably the Salmonoids, which take up nearly two-thirds of the volume, and whose study has probably occupied the author by far the better half of the eight years which he has devoted to its preparation

As regards the plan of the work, the thoroughness and originality with which the author treats his subject, and the fairness of his criticism of his predecessors, I may be allowed to refer to what I have said in my notice of the first volume of the Swiss ichthyology (NATURE, vol zxvii p 220); stating again that "this work rises far above the level of a local publication, and is of as great value to the student of European freshwater fishes as to the Swiss naturalist."

The species treated of in the present volume are the following. 3 loaches, 2 shad, 8 Coregon, 1 grayling, 1 saimon, 1 trout, 1 char, 1 pike, 1 Silurus, 1 eel, 1 burbot, 1 sturgeon, 3 lampreys These bring the total number of Swiss freshwater fishes to 51

The hydrographic system of Switzerland comprises the head-waters of four rivers, viz. the Rhine, Rhone, Po. and Danube. The first contributes the largest contingent to the Swiss fish fauna, viz 42 species; however, this number is reduced to 28 in the upper course of the river. above the falls of Schaffhausen At an altitude of between 600 and 900 m. the majority of the Cyprinoids, and between 1000 and 1100 m the perch, salmon, eel, and burbot disappear Only five species remain at that altitude, viz the miller's thumb, minnow, loach (N barbatulus), grayling, and trout-species which likewise have the greatest horizontal range in a northward direction Between 1800 and 1900 m, first the grayling and the loach are lost, and then successively the trout, miller's thumb, and minnow The trout, however, can still subsist in lakes up to 2630 m, into which this fish has been introduced. The Rhine contributes five types of fishes to the Swiss fauna which are not found in the other hydrographic systems, viz Acerina (the pope), Rhodeus, the salmon, the sea lamprey, and the stickleback. absence in the southern and eastern waters of the four first is readily accounted for by their distribution generally; but it seems very singular that a fish like the stickleback, which in the west of Europe extends far southwards, and reaches even Algeria, and which is supposed to be capable of easy transportation by aquatic birds, should not have made its way into the other riversystems.

The fishes contributed by the Rhone fall into two categories—one comprising those of the part of the River Doubs which is within the political boundaries of Switzerland; the other including the species of the Rhone proper above the "Perte." The latter are computed to be 20 in number, and do not call for special remarks.

The fishes of the Po show a marked difference from those of the Rhine and Rhone. This system is represented in Switzerland by the tributary Ticino, into which is specified in Switzerland by the tributary Ticino, into which the fishes of the Po, used to a warmer climate, avoid not ascending into the cold waters from the Alps, and M. Falio observes, also, that generally these southern fish do not ascend to the same high altitudes as those of the Rhine Eight of the Ticino species are strangers to the rest of Switzerland, vir. a goby (Gobius), which has ascended from the sea; five Cyprinoids, which has ascended from the sea; five Cyprinoids, which has be regarded as southern representatives of northern forms; Cobbits towar and Aloss finite.

Of the 68 species belonging to the fauna of the Danube, only four find their way into Switzerland through the River Inn, viz the iniller's thumb, minnow, grayling, and trout. This is owing to the great elevation of this river at its entrance into the country (1000 metres)

Ichthyologists will turn with particular interest to that part of the volume which contains Dr. Fatio's views on, and his treatment of, the Salmonids; for my own part. I could not help feeling some surprise at what appears to me a somewhat inconsistent mode of dealing with this subject. Whilst the author distinguishes not less than eight Swiss forms worthy of binominal designation in the genus Coregonus, he admits, besides one species of char (Salmo umbla), two equivalent forms only in the genus Salmo, viz the salmon and the trout, for which latter the collective term Salmo lacustris is chosen. If a student of the European fauna, or any part of it. arrives at the conclusion that the various forms of river, lake, and sea trout cannot, and should not, be held to be deserving of specific distinction, no one will deny that there are very strong arguments in favour of this view. In my own experience it does not seem to be desirable to adopt that course - first, because there are certain well characterized and well localized forms which the practical fisherman will always distinguish, and of which the naturalist has, somehow, to take notice; and, secondly, because the ichthyologist who goes beyond the narrow limits of a fauna, and has to deal with the trout of the whole northern hemisphere, is compelled by technical considerations to admit those distinctions. I myself go a step further, and consider it a mistake not to separate, specifically, from the extremely variable Salmo farso, such strongly differentiated forms as Salmo lemanus, S. marsitu. S. venernensis, or the Loch Leven trout of the older authors But if, as is Dr. Fatio's opinion, no taxonomic value is to be assigned to the characters by which those forms of trout are differentiated, then I cannot see why in Coregonus, a closely related genus of the same geological age and distribution, similar organic modifications should be considered to have a different bearing

As is well known, there are some very obscure facts in the life-history of Salmonoids which greatly contribute to the difficulties of their study. Dr. Faito discusses them very fully, but we must pass over the deductions he draws from them, with the exception of the phenomenon of sternity as a cause of change in the outward appearance of a fish. Sternity among Salmonoids is apparently much more common in Switzerland than in British waters; but ever since Sebold lias drawn attention to it, its effects seem to me to have been exaggerated. At any rate, I have received specimens as, and, indeed, with all the outward characters of, the so-called sterile trout of Lake Constance, which had fully matured ova.

Like errata, appendices of works are only too often overlooked, I would therefore mention that the present volume concludes with important supplements to those which contain the Mammalia and Repitlia

The volume is illustrated with four plates—one representing the *Bondelle* of the Lake of Neufchâtel, the others various details of structure, chiefly of Salmonoids

I trust that before many years Dr Fatio will be able to complete his work, for which, not only his countrymen, but every student of the European fauna, owe him a debt of gratitude ALBERT GUNTHER

THE HISTORY OF MARRIAGE.

The History of Human Marriage By Edward Westermarck (London, Macmillan and Co., 1891)

BY "history" our author means "natural history" (p. 19), and his reason for using the odd term "human marriage" is that "marriage, in the natural history sense of the term, does not belong exclusively to our species" (p 6) According to him, "marriage is nothing else than a more or less durable connection between male and female, lasting beyond the mere act of propagation till after the birth of the offspring." In this sense marriage is " an almost universal institution among birds," and "occurs as a rule among the monkeys, especially the anthropomorphous ages, as well as in the races of men" (p 20). Among mankind it is universal, and in all probability is "an inheritance from some ape-like progenitor" (p 538). In this book, therefore, marriage is taken to mean what ordinary people call "pairing, and the professed subject of the volume is the natural history of the habit of pairing in the human race. But surely, on any proper use of terms, marriage is not simple pairing, but such pairing as is protected and regulated by law, or by the public opinion which in rude societies stands for law And the history of an institution which is controlled by public opinion and regulated by law is not natural history. The true history of marriage begins where the natural history of pairing ends

Mr. Westermarck's definition leads him to go at length into various topics that really belong to natural history, but have hitle or nothing to do with the history of marriage in the ordinary sense of the word, such as sexual selection, and the means used by one sex to attract the other. But he also deals with polyandry, kinship through females only, infanticide, exogamy—diof which belong to the sphere of law and custom, within which his definition of marriage is totally inapplicable. To treat these topics as essentially a part of the natural history of

pairing involves a tacit assumption that the laws of society are at bottom mere formulated instincts; and this assumption really underlies all our author's theories. His fundamental position compels him, 'he will be consistent with himself, to hold that every institution connected with marriage that has universal validity, or forms an integral part of the main line of development, is rooted in instinct, and that institutions which are not based on instinct are necessarily exceptional, and unimportant for scientific history. One does not expect a catcit assumption to be carried out with perfect consistency, but, on the whole, Mr. Westermarck's results correspond with his assumption, and have no evidence to satisfy anyone that is not prepared to share the assumption with him.

To show this at length would exceed the limits of a short review; let us, however, take, as a crucial test, Mr Westermirck's explanation of the origin of exogamy. He believes that exogamy and all laws of incest originate in instinctive aversion to sexual interconsists between persons living closely together from early youth (p 330), and the origin of this instinct he explains as follows. He thinks it can be proved that consanguineous marriages are detrimental to the species. Now,

"among the ancestors of man, as among other animals, there was, no doubt, a time when blood-relationship was no bar to sexual intercourse. But variations, here as elsewhere, would naturally present themselves, and those of our ancestors who avoided im-and-in breeding would survey, while the others would gradually decay and ultimately perish. This an instinct would be developed which would be powerful enough, as a rule, to prevent injurious unions. Of course, it would display itself with others with whom they tived, but these, as a matter of fact, would be blood relations, so that the result would be survival of the fitter if no 523.

The obvious and fatal objection to this theory is that it postulates the evisience of groups which through many generations (for the survival of the fittest implies this) avoided wiving within the group. And this is, in fact, a well-established custom of ecogamy, so that the theory begins by postulating the very custom that it professes to explain. Moreover, it is questionable whether Mr. Westermarck's theory even helps to explain the wide diffusion of evogamy. For where wiving outside the local group is the rule, all neighbouring groups mingle their bloods, and consanguineous marriages are not escaped.

It is not surprising that Mr Westermarck, with his habit of looking at the whole subject from a biological point of view, should have little sympathy with the speculations of a man like McLennan, to whom marrage is not a mere fact of natural history, but a relationship resting on contract and approved by custom or law, and who in all his investigations gives weight to the action of human intelligence as the decisive factor in social progress. But it is a pity that this lack of sympathy has sometimes prevented our author from appreciating the full scope of McLennan's methods and arguments. What is said about the Levirate at pp 510-14 could not have been written if Mr. Westermarck had carefully read the discussion of the subject in "The Patriarchal Theory";

have made the error of confounding the Hindu Levirate with the Nyoga (p. 144, note). And here I may also note that the criticism of McLennan's views of exogainy does not take account of the posthumous and very important paper published in the English Historical Review for January 1888.

These are details what is more to be regretted is that Mr. Westermarck has not learned, as he might have done from McLennan, a sounder method of handling the evidence drawn from the usages of rude societies The very possibility of reconstructing the history of human progress rests on the fact that all over the world mankind has been moving in the same general direction, but at very various rates, and that careful reasoning, aided especially by the observation of cases which exhibit a state of transition (eg from one type of kinship to another), enables us to bring out the order in which the various observed types of social structure succeed one another Of all this, Mr Westermarck does not seem to have the least idea. He collects facts about the prevalence of kinship through males or through females, about forbidden degrees, and so forth, without ever rising to the conception that the evidence is good for anything more than an inductio per enumerationem simplicem not the way in which real progress can be made

W ROBERTSON SMITH

OUR BOOK SHELF.

Geological Majo of Monte Somma and Tenurus Constructed by II. J. Johnston-Lurs, M. D. M. R. C. S. B. els-Sc, F. G. S., &c., during the Years 1880-88 Scale, I. 10,000 (63) miches = 1 mile! In Six Sheets, with a Pamphlet criticle "A Short and Concise Account of the Eruptive Phenomena and Geology of Monte Somma and Vesuvius" (London George Philip and Son, 1891)

DUAING the latter half of last century, the changes taking place in Vesuvius were carefully studied and fathfully chronicled by an English diplomatist—Sir William Hamilton, in the closing years of the present century, the control of the control o

In his general memor on the geology of Somma and Vesuvisi, the author has divided the time covered by the history of the volcano into four "sras," and these again into eight "phase," while some of the latter are subdivided into "iperiods". In colouring the map, it has, of course, not been found possible to give expression to anything like such a minute classification of the rocks composing the mountain as is implied in such a scheme. The legend on the map recognizes as the great landmarks in the past that the property of the proposition of the past of

publication. Dr Johnston-Lavis has added one more to the long list of valuable services which he has rendered

to geological science Les Sciences Naturelles et l'Éducation Par T H. Huxley.

Édition Française (Paris Baillière et Fils, 1891) THIS is a translation of various essays with which all English students of Prof Huxley's writings have long been familiar Most of them deal with various aspects of the question as to the true place of science in a proper system of education , and no one who has read them in their original form is likely to have forgotten the philosophical power with which the subject is discussed or the admirable lucidity, strength, and grace of the writer's style With his educational papers Prof Huxley has associated his well-known essays on Descartes and Auguste Comte, which cannot fail to be of interest to French readers. He contributes to the volume a short preface, in which he refers with satisfaction to the astonishing advance that has been made in the recognition of science as an instrument of education He warns men of the younger generation, however, that the battle has only been half won, and that much serious work will have to be done to secure the triumph of the principles for which he has contended Of the translation it may be enough to say that Prof. Huxley cordially commends it as a faithful rendering of his thought.

W. E Weber

In the article on Wilhelm Weber (NATURE, July 9, p. 229) no mention is made of the fact that Weber and Gauss in 1833 invented and constructed a telegraph connecting the Physical Laboratory of the University in Gottingen with the Observatory In Germany they are for this reason said to be the inventors of telegraphy. This is, to say the least, a somewhat sweeping statement, as the possibility of communicating by electricity was statement, as the possibility of communicating by electricity was whether and Gots played some just in introducing being that into practice. For my just 1 consider the purely scientific work of either of the two min more glottous. For the corrosion practical consequences of telegraphy have nothing to do with the scientific ment of the invention. Nevertheless 1 thack that an article on Wilhelm Weber would not be complete without entering into this subject
Hanover, Technische Hochschule, July 13 C RUNGS

[Conducting wires were erected between the Gottingen Conducting wires were erected between the Gottingen Observatory and the Physical Cabinet of the University, distant about three quarters of an hinghish mile, in order to obtain accurate comparisons of the clocks. But, in addition to systematic daily transmission of time, the wires were from the first forestending the clocks of the control of the con frequently used for telegraphic purposes, though, with the first arrangements, only two letters could be sent in a minute—G C. Earthquake Shocks in Italy and Australia.

By a telegram from London, which appeared in the newspapers here on the 12th and 13th inst, information is given of a severe earthquake in Italy (about Vesuvius) on June 7 (Sunday). On that day, several distinct and well marked shocks were felt over parts of the south of Australia, and as there may be some connection between these seismic disturbances in both hemispheres, I give below the times and other information of the disturbances experienced here.

None of the disturbances reported in Australia seem to have been more than a "shake" or share tremor sufficient to shake windows and rattle crockery, &c., but they were enough, in some instances, to produce feelings of nausea

NO. 1134, VOL. 441

June 7, at 2 5 p m, the first disturbance occurred, and was felt all around Melbourne and over a surrounding area of 360 square miles.

June 7, at 2 45, another shake (not so great as the first) was o felt : in this case it was felt most severely to the east of Melbourne

June 7, at 7 20, smart shock felt at Kapunda, South Australia. June 7, at 6 45, slight shock felt at Stockport, South ustralia. The direction of motion is vanously given as from north west to south east, south east to north-west, and south-west to north-east, north to south, south to north, &c. The conclusion arrived at is that the wave was from south to north nearly. The approximate geographical positions of the several

Melbourne	37 50 S.	144 58 E.
Melbourne, June 15		R L. J. ELLERY.

P.S -It is quite probable the shocks felt at Kapunda and Stockport were one and the same, as time is not very strictly kept in districts distant from large towns in Australia,

Force and Determinism.

I see nothing to criticise in Mr. Dixon's middle paragraph, wherein he accurately summarizes some of the definitions of mechanics, every that I should prefer to express the menuing of his last sentence by saying that, if in any department something simulated the functions of, say, energy, without obeying its precise mechanical laws, then the distinction between energy and that stomething should be clearly recognized, and another name be given to it.

I find it rather common for "life" to be thought of and classed under the head energy, either by the use of a phrase such as "vital energy," or in a more direct way, the reason being apparently that organisms while living simulate some of the apparently that Organisms when Irving simulate some of the functions of energy, and cease to do so when dead It was against this confusion that I wrote on p 401 (vol xlin.)

Life has not yet been included in the domain of physics, neither has it, so far as I am aware, been much studied under

the head biology.

And yet the disturbing action of live animals will have to be formulated and attended to some day, even in physics, for, though they generate no energy nor affect its amount in the slightest degree, they certainly control it and direct it in channels it would not otherwise have taken. The question is, How do they manage this? And one answer that may be given is, By exerting

manage this? And one answer that may be given is, By exerting directive or guiding forces on matter.

Of course they are not limited to this, but in so far as they do work their action is fairly understood—the energy displayed by a gang of navives is known to be derived from the little tin cans. they bring with them. the energy is not their shut their victuals', they simply direct it. But how comes it that they can direct the energy of victuals and atmosphere into the erection of the precise bridge or other structure which has been planned? What determines the direction of the transfer of energy?

The same question may doubtless be asked in connection with inanimate activity · I would not be understood as assuming for certain any clear or essential difference between the two cases . but in neither case do I know the answer

The action of force in doing work, se transferring and transforming quantities of energy, has been thoroughly attended to
The action of force in directing and guiding the transfer of
matter and energy does not seem to me to have been seriously contemplated

In his most recent book ("The Philosophical Basis of Lvolution") Dr. Croll attacks the problem, and says that guidance is effected by "determinism" not by force. But that cannot be admitted; for without force the motion of matter cannot be changed in direction any more than in speed. Force is certainly necessary to direct the motion of matter, it is energy only which is unnecessary; for any transfer of energy that may occur is an accidental, not an essential, concomitant.

I determine to move an object: it may be only my finger, or it may be a wheelbarrow In so far as I do any work in the action I do so at the expense of my food, and there is nothing but a chemical difficulty about that The mystery begins when one caks how I manage to direct that energy along a definite path so as to produce a willed result. The only answer I know is, "by a nervous implies libraried from brain centres." But what is it that is thus liberated? and what pulls the trigger to liberate it? By mechanical analogy one would say that energy can only be guided by force, and that force must therefore be exerted as the brain celler; but, if so, the relation between force, which is a

mechanical thing, and will or life, or whatever it is, which is a

psychological thing, demands investigation
I trust that Mr Lloyd Morgan will help me to get my ideas
on these subjects straighter, and will point out if I have made any assertions which are obviously erroneous or grotesque. The borderland of psychology and physics is the last place in which I would like to dogmatize, and in a letter like this I see no harm though the to augmente, and in a section that the interior in airing confessedly immature and groping notions, in the hope that ventilation may clear the air. So far as physics only is concerned. I have stated how I regard the phrase "expenditure of tent ventuation may clear the air So are as physics, cerned, I have stated how I regard the phrase "expenency" in the Philosophical Magazine for June 1885

With regard to the crux raised in Mr Dixon's last paragraph, that nothing but matter can exert force, because the acting matter that nothing but matter can exert force, because the exting matter must receive an equal opposite momentum, it may perhaps be just worth noticing that an infinite mass can absorb any amount of momentum without receiving a trace of energy or being itself in any way affected. OLIVIR J LODGS.

Liquid Prisms

I OBSERVE in NATURE of July 2 (p 207), that it is stated Herr Wolter has recently recommended a monobromnaphthalene as a substance peculiarly fitted for study of the ultra violet part of the spectrum, by reason of its high dispersive power and trans-parency for the ultra-violet rays.

pareincy for the ultra-voict rays.

Perhaps I may be permitted to state that Mr Madan published an account of 1st diagention and refractive power in the inheritance of the diagention and refractive power in the made use of many other whataness, including methy salicylate, I gave this a trial. For ordinary work it would be excellent of Coolurles, but unfortunately, no matter how free from colours it may be when freshly prepared, long-continued use causes at to become yellow, and in considerable thicknesses even dark bowen For the ultra-violet rays it is undoubtedly better than carbon disulphide, but nevertheless tractically useless, as the line N, which it is said to transmit, has a wave-length of 3580, so that only about one half of the ultra-violet solar rays are observable with it. In metallic spectra almost all lines of interest he between 3580 and 2000 A liquid which I considered to possess oetween 3300 and 2000. A figuid which I considered to possess much superior optical properties is mexister methods, it is perfectly colourless, and of such density that fliot glass will float upon it. When the glass is immersed it becomes unvisible, consequently the refraction and dispersion of the liquid are probably seceptionally high. As far as I can recollect, being without access to my notes, a thickness of 50 millimetres freely transmitted all rays to about \$\lambda\$ 2000—that is to say, the entire solar spectrum Unfortunately, it has its drawbacks, in being somewhat volatile, and its vapour highly poisonous

The Identification of Templeton's British Earthworms

BETWEEN the years 1829 and 1836 the first series of Loudon's Magazine of National Missions appeared in mine volumes. In the last volume we find some notes on earthworms by Templeton, which have proved somewhat puzzling to students of more recent times. I have been fortunate enough to follow Templeton in some of his researches, and am able to correct and verify certain

of his statements

of his statements. The Lumbreus vanihurus, Temp (op. cst., 1x 235), is the angler's gilt tail, and as such is synonymous with Jumbreus pater, Hoffm., and Dendrobena Beedest, Elem. Lumbreus gardnams, Temp. (be cst.), is undoubtedly the mucous worm (Allelolophone mucous, Etend, or one of its near alize, all of which are to be found of a pale rosy colour coiled up into a knot at certain times of the year.

It is to Lumbricus ontilurus (= Omilurus rubescens, Temp., lo 13.) however, that I wish to direct special attention Grube, in 1851 ("Familien der Anneliden," p. 101), placed it, with Templem of the Ormon, in a list of species which were insufficiently characterized for systematic parposes. Vejdowick, in 1884 ("System and Morph, der Oligochwein," p. 63), places it among

the questionable species without note or comment, and, so far as can gather, no one has been able to throw light upon it since Templeton says the worm is never larger than half the size of

Templeton says the worm is never larger than hall the size of \$L\$ terrettrs, \$L_1\$ to \$a\$ bught reddish brown, with the tail very flat, and the body unfurnished with a belt at the position of the serval organs. It would be very easy to suppise from this somewhat wague account that the writer had only seen immature specimens; but a little careful study of his words shows that he Specimens; out a fifte careful study of his words shows that he knew what he was writing, and that his worms were mature. Now a mature species of *Lumbricus* without a chiellum is certainly an anomaly, and needs investigation

While collecting Annelids recently, I came across half a dozen specimens which at first sight exactly resembled Lumbricus rubellue, Hoffin I took them home for verification, and infinediately observed the difference I had obtained with them typical specimens of rubdius, which enabled me to make a careful com-

specimens of violents, which established in to make a careful com-parison of the two species in a living state.

The following is a description of the worm as I wrote it down before observed in the control of the control of the con-being dependent of the control of the control of the becoming lighter towards the posterior extremity, which is flesh-benous grapher towards the posterior extremity, which is fleshcoloured or light red, pink ventrally Prostomium dovetailing completely into the peristomium, and posses ing a transverse groove in the middle, as snown in the accompanying sketch

Lumbricus rulescent Segments 1 to 3 with prostomium entirely cutting the first segment or peristomium

Segments not annulated (or divided by transverse rings) Length about 3 inches, total number of segments about 120 Setæ in couples as in typical Lumbricus. Male or spermiducal pores on segment 15 with papillae, which, however, do not extend over the neighbouring segments. Body cylindrical in front, flattened posteriorly. The dorsal pore between 5 and front, flattened posteriorly. The dorsal pore between 5 an 6. It appeared at first between 7 and 8, but by usin polarized light on the cuticle, when spread on a glass slip it whole series of pores in one or two specimens became clearly visible from the fifth segment backwards

value from the fifth segment backwards.

On the wentral surface prominent papilæ appeared on segments 28 and 29, such as are often seen on typical L agreeda, 10.6fm. Now came the crucial question, I st there no clinellum? By studying all the examples carefully, I found that they agreed in one particular. The segments 34 to 39 differed in structure from the rest on the dorsal surface. On the under surface from 33 to 40 were differentiated, and showel a glandular structure, while the band representing the tubercula pubertaits extended

distinctly along the ventral surface of 35, 36, 37, 38

This description of the external characters shows the worm to be a decided Lumbreux, tested by Dr Benham's definition in 'An Attempt to Classify Earthworms', but it differs from every one of our British species, especially in the backward position and inconspictions nature of the clitellum I am unable to refer it definitely to any of the European species, and propose that for the present it should be known as Lumbricus rubescens (Temp), thus retaining the two names from Templeton's synonyms which are most appropriate to what I regard as the species intended by him
I may add that I have recently found one or two other earth-

worms in Yorkshire which have not yet been recorded as British, and will form interesting additions to our Annelid fauna Idle, near Bradford, July 15 Ilii DERIC F

Are Seedlings of Hemerocallis fulva specially Variable?

I SHALL be grateful to any of your readers who will write and terr experiences as to the variability of seedlings of Hemerocaliss fulva, or who will raise it from seed in fair quanti and kindly communicate to me their results, which shall be duly acknowledged

My reason is this there is in the formation of the police in this plant a peculiarity which, according to Weismann's views, should lead to excessional variability in the secilings, but, so

Royal University, Dublin, July 9

The Green Sandpiper

On Sunday last, July 12, I saw flying round a large pool in Essex, a specimen of the green sandpiper. It flew leisurely round the pool, and seemed as if it were not far from its summer home. I think, therefore, that the bird must be nesting in the

county, and probably in the neighbourhood

Can any of your correspondents inform me whether the nest
has been found anywhere, in recent years, in England? ARGVII.

Argyll Lodge, Kensington, July 17

LIQUIDS AND GASES!

A LMOST exactly twenty years ago, on June 2, 1871, Dr Andrews, of Belfast, delivered a lecture to the members of the Royal Institution in this hall, on "The Continuity of the Gaseous and the Liquid States of Matter" He showed in that lecture an experiment which I had best describe in his own words -

"Take, for example, a given volume of carbonic acid at 50°C, or at a higher temperature, and expose it to increasing pressure till 150 atmospheres have been reached. In the process, its volume will steadily diminish as the pressure augments, and no sudden diminution of volume, without the application of external pressure, will occur at any stage of it When the full pressure has been applied, let the temperature be allowed to fall, until the carbonic acid has reached the ordinary temperature of the atmosphere During the whole of this operation, no break of continuity has occurred. It begins with a gas, and by a series of gradual changes, presenting nowhere any abrupt alteration of volume, or sudden evolution of heat, it ends with a liquid

1 Lecture delivered by Prof W Ramsay, F.R S, at the Royal Institution Friday, May 3

NO. 1134, VOL. 44]

"For convenience, the process has been divided intotwo stages—the compression of the carbonic acid, and its subsequent cooling But these operations might have been performed simultaneously, if care were taken so to arrange the application of the pressure and the rate of cooling, that the pressure should not be less than 76 atmospheres when the carbonic acid had cooled to 31

I am able, through the kindness of Dr Leits. Dr. Andrews' successor at Belfast, to show you this experiment, with the identical piece of apparatus used on the

occasion of the lecture twenty years ago

I must ask you to spend some time to-night in con-sidering this remarkable behaviour, and, in order to obtain a correct idea of what occurs, it is well to begin with a study of gases, not, as in the case you have just seen, exposed to high pressures, but under pressures not differing greatly from that of the atmosphere, and at temperatures which can be exactly regulated and measured Io many here to-night, such a study is unnecessary, owing to its familiarity, but I will ask such of my audience to excuse me, in order that I may tell my story from the beginning.

Generally speaking, a gas, when compressed, decreases in volume to an amount equal to that by which its pressure is raised, provided its temperature be kept constant. This was discovered by Robert Boyle in 1660, in 1661 he presented to the Royal Society a Latin translation of his book, " Fouching the Spring of the Air and its Effects"

His words are -

"'I's evident, that as common air, when reduced to half its natural extent, obtained a spring about twice as forcible as it had before, so the air, being thus compressed, being further crowded into half this narrow room, obtained a spring as strong again as that it last common air "

To illustrate this, and to show how such relations may be expressed by a curve, I will ask your attention to this model We have a piston, fitting a long horizontal glass tube confines air under the pressure of the atmosphere—that is. some 15 pounds on each square inch of area of the piston The pressure is supposed to be registered by the height of the liquid in the vertical tube. On increasing the volume of the air, so as to double it, the pressure is decreased to of the air, so as to double it, the pressure is because to half its original amount. On decreasing the volume to half its original amount, the pressure is doubled again halving, the pressure is again doubled. Thus you see a curve may be traced, in which the relation of volume to pressure is exhibited Such a curve, it may be remarked

incidentally, is termed an hyperbola

We can repeat Boyle's experiment by pouring meicury into the open limb of this tube containing a measured amount of air, on causing the level of the mercury th the open limb to stand 30 inches (that is, the height of the barometer) higher in the open limb than the closed limb, the pressure of the atmosphere is doubled, and the volume is halved And on trebling the pressure of the atmosphere the volume is reduced to one-third of its original amount, and, on adding other 30 inches of mercury, the volume of the air is now one-quarter of that which it originally occupied

It must be remembered that here the temperature is kept constant; that it is the temperature of the surround-

ing atmosphere
Let us next examine the behaviour of a gas when its temperature is altered, when it becomes hotter This tube contains a gas-air-confined at atmospheric pressure by mercury, in a tube surrounded by a jacket or mantle of glass, and the vapour of boiling water can be blown into the space between the mantle and the tube containing the air, so as to heat the tube to 100', the temperature of the steam The temperature of the room is 17° C., and the gas occupies 290 divisions of the scale. On blowing in steam, the gas expands, and on again equalizing pressure, it stands at 373 divisions of the scale. The gas has thus expanded from 200 to 273 divisions, 7. ets volume has increased by 83 divisions, and the temperature has risen from 17° to 10°, 12° through 83°. This law of the expansion of gases was discovered almost simultaneously the contract of the contract o

We have experimented up to the present with air—
mixture of two gases, oxygen and nitrogen, and the
boling-points of both of these elements he at very thoboling-points of both of these elements he at very the
ordinary atmospheric temperature he a long way above
the boiling-points of liquid oxygen and liquid nitrogen at
the ordinary atmospheric pressure. But it is open to us to
study a gas, which, at the ordinary atmospheric temperature
1 shall choose water-gas in order that it may be a gas at
ordinary atmospheric pressure, however, we must heat it
to a temperature above 100° C, its boiling-point. This
tube contains water-gas at a temperature of 100° C, it
at the same level in both the tubes and in this reservoir,
which communicates with the lower end of the tube by
means of the india-rubber tubing. The temperature
105' is manutaned by the vapour of chlorobenzene, boiling
that of the atmosphere.

Let us now examine the effect of increasing pressure. On raising the reservori, the volume of the gas is dimmished, as usual, and nearly in the ratio given by Boyle's law, that is, the volume decreases in the same proportion as the pressure increases. But a change is soon observed; the pressure soon ceases to rise: the distante hetween the mercury in the reservoir and that in the tube remains constant, and the gas is now condensing to liquid. The pressure continues constant during this change, and to have been decreased in the constant during the change, and in the water gas has condensed to liquid only when all the water gas has condensed to liquid offensed, an enormous increase of pressure is necessary to densed, an enormous increase of pressure is necessary to water scarcely yields to pressure, and in such a tube as this, no measurements could be attempted with success.

Representing this diagrammatically, the right-hand part of the curve is, as before, nearly a hyperbola. Then and the curve is, as before, nearly a hyperbola. Then without rise of pressure, represented by other occurs without rise of pressure, represented by other occurs without rise of pressure, represented by other occurs as in presence of water; the vertical, or nearly vertical line represents the sudden and great rise free the present of water gas as the present of the present of water gas to the present of the present of water gas obtained by the present of the present of water gas obtained by the present of the present of water gas obtained by the present of the gas of of

slight decrease of volume of water produced by a great morerase of pressure. And we should have similar lines for 120°, 130°, 140°, 150°, and for all temperatures within certain limits. Such lines are called isothermal lines, or shortly "isothermals," or lines of equal temperature, and represent the relations of pressure to volume for different temperatures.

different temperatures
Dr Andrews made similar measurements of the relations between the pressures and volumes of carbon
for the pressures and volumes of carbon
shown you for water. But I briefer in speak to you
about similar results obtained by I'rof Sydney Young
and myself with ether, because DI Andrews was unable
to work with carbon dioxide free from air, and that infleeneed his results. For example, you see that the
meeting-points of his hyperbolic curves with the straight
is caused by the presence of about 1 part of air in 500
parts of carbon douded, also the condenstroin of gas
accompany of the presence of about 1 part of air in 500
parts of carbon douded, also the condenstroin of gas
change from a mature of liquid and gas to liquid
when were more easily able to fill a tube with ether
free from air, and you will notice that the points I have
referred to are angles, not curves

Let me first direct your attention to the shapes of the curves in the diagram. As the temperature rises, the apour-pressure lines les at higher and higher pressures, and the lines themselves become shorter and shorter. And finally, at the temperature 31° for carbon dioxide, and at 193° for ether, there ceases to be a horizontal at one control of the state of the stat

When a gas is compressed, it is heated Work is done on the gas, and its emperature rises If I compress the air in this syringe forcibly, its temperature rises so high that I can set a piece of indeer on fire, and by its help explode a little gunpowder. If the ether at its critical point be compressed by screwing in the screw, it is somewhat warmed, and the blue cloud disappears. Conversely, increasing its volume, it is cooled, and a dense must is seen, accompanied by a shower of either rain. This is seen as a black fog on the screw.

I wish also to direct your attention to what happens if the volume given to the ether is greater than the critical volume—on increasing the volume, you see that it boils away and evaporates completely, and also what happens if the volume be somewhat less than the critical volume it then expands as liquid, and completely fills the tube. It is only at the critical volume and temperature that the pressure. If the volume be too great, the pressure is below the critical pressure; if too small, the pressure is hugher than the critical pressure.

Still one more point before we dismiss this experiment. At a temperature some degrees below the critical temperature, the mensions, e. the surface of the liquid, is curved. It has a skin on its surface; its molecules, as Lord Rayleigh has recently explained in this room, attract one another, and It exhibits surface-tension. Raise the temperature, and the mensious grows flatter, raise it further, and it is nearly flat, and almost invisible; at the critical temperature it disappears, having first become quite flat surface-tension, therefore, disappears at the critical point.

A liquid would no longer rise in a narrow capillary tube; it would stand at the same level outside and inside

It was suggested by Prof James Thomson, and by Prof Classuss about the same time, that if the sideal state of things were to exist, the passage from the liquid to the gaseous state should be a continuous one, not merely at and above the entical point, but below that temperature and the suggested that the curves, shown in the figure, and the suggested that the curves, shown in the figure, pressure, should continue sinuously. Let us see what this conception would involve.

On decreasing the volume of a gas, it should not liquefy at the point marked B on the diagram, but should

still decrease in volume on increase of pressure. This decrease should continue until the point E is reached. The anomalous state of matters should then occur, that a decrease in volume should be accompanied by a decrease of pressure. In order to lessen volume, the gas must be exposed to a continually diminishing pressure. But standard is of its nature unstable, and has a contain part of the standard in the curve is continuous with the realizable curve representing the compression of the lound, about the standard in the

compression of the loquid, above D
Dr. Sydney Young and I succeeded, by a method which
I shall briefly describe, in mapping the actual position
of the unrealizable portions of the curve They have the

NO. 1134, VOL. 44

form pictured in this figure. The rise from the gaseous state is a gradual one, but the fall from the liquid state is abrupt.

Consider the volume 14 cubic centimetres per gram on the figure. The equi-volume vertical line cus the isothermal lines for the temperatures 175, 1867, 1857, 1007, and so on, at certain definite pressures, which may be read course of times of equal volume, of which the instance given is one, using temperatures as ordinates and pressures as abscissas. We can thus find the relations of temperature to pressure for certain definite interactions of times and the read of the control of the simplest pressure is a linear function of temperature. Expressed

$$p = bt - a$$

where h and a are constants, depending on the volume. Checken, and waying with each volume. But a straight line may be extrapolated without error, and to, having found values for a and h for such a volume as 6 c c per gram, by help of experiments at temperatures higher than 1957, it is possible by extrapolation to obtain the pressures corresponding to temperatures below the critical that the substance at volume 6 is in practice partly liquid and partly gas. Yet it is possible by such means to ascertain the relations of pressure to temperature for the unrealizable portion of the state of a liquid—that is, we can deduce the pressures and temperature corresponding to a manner the thange from liquid on gas. And in this manner the amounts have on the figure have been constructed.

It is possible to realize experimentally certain portions of such continuous curves. If we condense all gaseous ethers, and, when the tube is completely filled with liquid, either and, when the tube is completely filled with liquid to the considerably below the vapour pressure corresponding to the temperature of ebullition, without any change further tendercon of pressure—an expansion too small to be seen reduction of pressure—an expansion too small to be seen pressure, such expension of the control of the liquid suddenly changes into gas, while the pressure rises quickly to the yapour-pressure corresponding to the temperature. If we are successful in expelling all air or gas of the control of the curve can be experimentally vasibled.

of this curve can be experimentally realized. The first notice of this appearance, or rather of one owing its existence to a precisely similar cause, is due to thooke, the celebrated contemporary of Boyle. It is noted in the account of the proceedings of the Royal Society on November 6, 1672, Ital. "Mr. Hooke read a discourse of his, containing his thoughts of the experiment of the young of the containing his thoughts of the experiment specified by inches, together with some experiments made by him, in order to determine the cause of this strange phenomenn. He was ordered to prepare those experiments for the view of the Society." And on November 13 "the experiment for the view of the Society." And on November 13 "the experiment for the high suspension of quicksliver being called for, it was found that it had failed. It was ordered to hat thinker glasses should be provided for the next

There can be no doubt that this behaviour is caused by the attraction of the molecules of the liquid for each other. And if the temperature be sufficiently low, the pressure may be so reduced that it becomes negative—that is, until the liquid is exposed to a strain or pull, as is the mercury. This has been experimentally realized by M Berthelot and by Mr. Worthington, the latter of whom has succeeded in straining alcohol at the ordinary tem-

perature with a pull equivalent to a negative pressure of 25 atmospheres, by completely filling a bulb with alcohol, and then cooling it The alcohol in contracting strains the bulb inwards, and finally, when the tension becomes very great, parts from the glass with a

sharp " click '

To realize a portion of the other bend of the curve, an experiment has been devised by Mr. John Aitken. It is as follows.—If air—that is, space, for the air plays a secondary part—saturated with moisture be cooled, the moisture will not deposit unless there are dust-particles mousture will not deposit unless there are dust-particles on which condensation can take place. It is not at first evident how this corresponds to the compressing of a gas without condensation. But a glance at the figure will render the matter plain. Consider the isothermal 175° for ether, at the point marked A If it were possible to lower the temperature to 160°, without condensation, keeping volume constant, pressure would fall, and the gas would then be in the state represented on the isothermal line at G that is, it would be in the same condition as if it had been compressed without condensation

You saw that a gas, or a liquid, is heated by com-pression; a piece of tinder was set on fire by the heat evolved on compressing air. You saw that condensation of ether was brought about by diminution of pressure— that is, it was cooled. Now, if air be suddenly expanded, it will do work against atmospheric pressure, and will cool itself. This globe contains air, but the air has been filtered carefully through cotton-wool, with the object of excluding dust-particles. It is saturated with object or excituding dust-particles at its saturated with moisture. On taking a stroke of the pump, so as to exhaust the air in the globe, no change is evident; no condensation has occurred, although the air has been so cooled that the moisture should condense, were it possible
On repeating the operation with the same globe, after
admitting dusty air—ordinary air from this room—a slight fog is produced, and, owing to the light behind, a circular rainbow is seen, a slight shower of rain has taken place There are comparatively few dust particles, taken piace Inere are comparatively tew dust particles, because only a little dusty air has been admitted. On again repeating, the fog is denser, there are more particles on which mosture may condense.

One point more, and I have done. Work is measured.

by the distance or height through which a weight can be raised against the force of gravity. The British unit of work is a foot-pound-that is, a pound raised through one foot; that of the metric system is one gram raised through one centimetre. If a pound be raised through two feet, one centimetre. It a pound be raised through two test, wice as much work is done as that of raising a pound through one foot, and an amount equal to that of raising two pounds through one foot. The measure of work is therefore the weight multiplied by the distance through which it is raised. When a gas expands against pressure, it does work The gas may be supposed to be confined in a vertical tube, and to propel a piston upwards, against the pressure of the atmosphere. If such a tube has a sectional area of one square centimetre, the gas in expanding a centimetre up the tube lifts a weight of nearly loop grams through one centimetre; for the pressure of the atmosphere on a square centimetre of surface is nearly 1000 grams—that is, it does 1000 units of work, or nearly 1000 grains—Inst 18, it does 1000 units of work, or ergs. So the work done by a gas in expanding is measured by the change of volume imultiplied by the pressure. On the figure, the change of volume is measured horizontally, the change of pressure vertically. Hence the work done is equivalent to the area. AECD on the figure

If liquid, as it exists at A, change to gas as it exists at B, the substance changes its volume, and may be made to do work. This is familiar in the steam-engine, where work is done by water, expanding to steam and so in-creasing its volume. The pressure does not alter during this change of volume, if sufficient heat be supplied, hence the work done during such a change is given by the rectangular area.

NO. 1134, VOL. 44]

Suppose that a man is conveying a trunk up to the first story of a house, he may do it in two (or, perhaps, a greater number of) ways. He may put a ladder up to the drawing-room window, shoulder his trunk, and deposit the drawing-room window, shoulder his trunk, and deposit it directly on the first floor. Or he may go down the area stairs, pass through the kitchen, up the kitchen stairs, up the first flight, up the second flight, and down again to the first story. The end result is the same; and he does the same amount of work in both cases, so far as conveying the weight to a given height is concerned, because in going down-stairs he has actually allowed work to be done on him, by the descent of the weight.

Now, the liquid in expanding to gas begins at a definite volume, it evaporates gradually to gas without altering pressure, heat being, of course, communicated to it during the change, else it would cool itself: and it finally ends as gas It increases its volume by a definite amount at a definite pressure, and so does a definite amount of work : this work might be utilized in driving an engine

But if it pass continuously from liquid to gas, the But it it pass continuously from induit to gas, the starting-point and the end point are both the same as before. An equal amount of work has been done. But it has been done by going down the area stair, as it were, and over the round I described before.

It is clear that a less amount of work has been done on the left-hand side of the figure than was done before and a greater amount on the right-hand side, and if I have made my meaning clear, you will see that as much less has been done on the one side as more has been done on the other—that is, that the area of the figure BEH must be equal to that of the figure AFH Dr Young and I have tried this experimentally—that is, by measuring the calculated areas, and we found them to be

equal.

This can be shown to you easily by a simple device namely, taking them out and weighing thein. As this diagram is an exact representation of the results of our experiments with ether, the device can be put in practice We can detach these areas which are cut out in tin, and place one in each of this pair of scales, and they balance The fact that a number of areas thus measured gave the theoretical results of itself furnishes a strong support of the justice of the conclusions we drew as regards the forms of these curves

To attempt to explain the reasons of this behaviour would take more time than can be given to-night; moreover, to tell the truth, we do not know them. But we have at least partial knowledge, and we may hope that investigations at present being carried out by Prof. Tait may give us a clear idea of the nature of the matter, and of the forces which act on it, and with which it acts, during the continuous change from gas to liquid

EXPERIMENTAL RESEARCHES ON MECHANICAL FLIGHT

THE following is a translation of a communication made by Prof. S. P. Langley to the Paris Academy of Sciences on July 13 :--

I have been carrying out some researches intimately connected with the subject of mechanical flight, the results of which appear to me to be worthy of attention They will be published shortly in detail in a memoir Meanwhile I wish to state the principal conclusions

In this memoir I do not pretend to develop an art of mechanical flight, but I demonstrate that, with motors having the same weights as those actually constructed, we possess at present the necessary force for sustaining, with very rapid motion, heavy bodies in the air; for example, inclined planes more than a thousand times denser than the medium in which they move.

Further, from the point of view of these experiments and

also of the theory underlying them, it appears to be demonstrated that if, in an acrial movement, we have a plane of determined dimensions and weight, inclined at such or determined dimensions and weight, inclined at such angles and moving with such velocities that it is always exactly sustained in horizontal flight, the more the velocity is augmented the greater is the force necessary to diminish the sustaining power. It follows that there will be increasing economy of force for each augmentation of velocity, up to a certain limit which the experiments have not yet determined. This assertion, which I make here with the brevity necessary in this résumé, calls for a more ample demonstration, and receives it in the memoir that I have mentioned

The experiments which I have made during the last four years have been executed with an apparatus having revolving arms about 20 metres in diameter, put in movement by a 10 horse-power steam-engine They are

chiefly as follows -

(1) To compare the movements of planes or systems of planes, the weights, surface, form, and variable arrangements, the whole being always in a horizontal position, but disposed in such a manner that it could fall freely (2) To determine the work necessary to move such

planes or systems of planes, when they are inclined, and possess velocities sufficient for them to be sustained by the reaction of the air in all the conditions of free horizontal flight. (3) To examine the motions of acrostats provided with

their own motors, and various other analogous questions that I shall not mention here

As a specific example of the first category of experi-ments which have been carried out, let us take a borizontal plane, loaded (by its own weight) with 464 grams, having a length 0.914 metre, a width 0.102 metre, a thickness 2 mm, and a density about 1900 times greater than that of the surrounding air, acted on in the direction of its length by a horizontal force, but able to fall freely
The first line below gives the horizontal velocities in

nietres per second; the second the time that the body took to fall in air from a constant height of 1 22 metres. the time of fall in a vacuum being o 50 second

When the experiment is made under the best conditions it is striking, because, the plane having no inclination, there is no vertical component of apparent pressure to prolong the time of fall; and yet, although the specific gravity is in this more than 1900 times that of the air, and although the body is quite free to fall, it descends very slowly, as if its weight were diminished a great number of times. What is more, the increase in the time of fall is even greater than the acceleration of the lateral movement.

The same plane, under the same conditions, except that it was moved in the direction of its length, gave analogous but much more marked results; and some observations of the same kind have been made in numerous experiments with other planes, and under more varied

conditions

From that which precedes, the general conclusion may be deduced that the time of fall of a given body in air, whatever may be its weight, may be indefinitely pro-longed by lateral motion, and this result indicates the account that ought to be taken of the inertia of air, in acrial locomotion, a property which, if it has not been neglected in this case, has certainly not received up to the present the attention that is due to it By this (and also in consequence of that which follows) we have established the necessity of examining more attentively the practical possibility of an art very admissible in theory

-that of causing heavy and conveniently disposed bodies to slide or, if I may say so, to travel in air.

In order to indicate by another specific example the

nature of the data obtained in the second category of my experiments, I will cite the results found with the same plane, but carrying a weight of 500 grams, that is 5380 grams per square metre, inclined at different angles, and moving in the direction of its length. It is entirely free to rise under the pressure of the air, as in the first example it was free to fall, but when it has left its support, the velocity is regulated in such a manner that it will always be subjected to a horizontal motion

The first column of the following table gives the angle (a) with the horizon, the second the corresponding velocity (V) of blanement-that is, the velocity which is exactly sufficient to sustain the plane in horizontal movement, when the reaction of the air causes it to rise from its support, the third column indicates in grams the resistances to the movement forward for the corresponding velocities -a resistance that is shown by a dynamometer These three columns only contain the data of the same experiment The fourth column shows the product of the values indicated in the second and thirdthat is to say, the work T, in kilogram-metres per second, which has overcome the resistance. Finally, the fifth column, P, designates the weight in kilograms of a system of such planes that a 1 horse-power engine ought to cause to advance horizontally with the velocity V and at the angle of inclination a

	v	R	T = VR	P = 500 × 4554
45	11 2	500	56	68
30	106	275 .	29	130
15	11 2	128	14	26 5
10	12 4	88	1 1	34.8
5	15 2	45	0.7	55.5
2	20 0	20	0.4	95 0

As to the values given in the last column, it is necessary to add that my experiments demonstrate that, in rapid flight, one may suppose such planes to have very small interstices, without diminishing sensibly the power of support of any of them

It is also necessary to remark that the considerable weights given here to the planes have only the object of facilitating the quantitative experiments. I have found that surfaces approximately plane, and weighing ten times less, are sufficiently strong to be employed in flight, such as has been actually obtained, so that in the last case more than 85 kilogiams are disposable for motors and other accessories As a matter of fact, complete motors weighing less than five kilograms per horse-power have recently been constructed

Although I have made use of planes for my quantitative experiments, I do not regard this form of surface as that which gives the best results I think, therefore, that the weights I have given in the last column may be considered as less than those that could be transported with the corresponding velocities, if in free flight one is able to guide the movement in such a manner as to assure horizontal locomotion—an essential condition to the economical employment of the power at our disposal

The execution of these conditions, as of those that

impose the practical necessity of ascending and descend-ing with safety, belongs more to the art of which I have

spoken than to my subject.

The points that I have endeavoured to demonstrate in the memoir in question are:—
(1) That the force requisite to sustain inclined planes in

(1) that the force requisite to sustain inclined planes in horizontal aerial locomotion diminishes, instead of in-creasing, when the velocity is augmented; and that up to very high velocities—a proposition the complete ex-perimental demonstration of which will be given in my memoir; but I hope that its apparent improbability will be diminished by the examination of the preceding

(2) That the work necessary to sustain in high velocity the weights of an apparatus composed of planes and a motor may be produced by motors so light as those that have actually been constructed, provided that care is taken to conveniently direct the apparatus in free flight, with other conclusions of an analogous character

I hope soon to have the honour of submitting a more complete account of the experiments to the Academy

ON THE SOLID AND LIQUID PARTICLES IN CLOUDS 1

I N this paper are given the results of some observations made while on the Rigi in May last, on the solid and liquid particles in clouds. It was noticed, when making observations on the number of dust particles in the atmosphere, that when the top of the mountain was in cloud, the number of particles varied greatly in short intervals, while previous experience had shown that at elevated stations the number was fairly constant for long periods. In order to investigate the case of this want of uniformity in the impurity of clouded air, extreme conditions were selected. and the air tested in cloud and in the clear air outside of When this was done the clouded air was found to have always more dust in it than the air outside Its humidity was of course also greater The relative amount of dust in pure and in clouded air varied greatly Some parts of the cloud had only about double the number of particles there were in the clear air, while in other parts
the proportion was much greater. The best example
tested occurred on the 25th of the month, when there were observed 700 particles per c c in the clear air, while the number in cloud went up to over 3000, and in one cloud to 4200 particles per c. These observations were taken on the top of the mountain while the clouds were passing over it, the readings being taken in the cloud and

again when it had passed and was replaced by clear air. These observations at once showed the cause of the variability in the number of dust-particles in the clouds the dust acted as a kind of ear-mark, and showed that the air forming the clouds was impaire valley air, which impure air had become more or less mixed with the purer upper air. Where little of the impure air had mixed with the upper air, the number of particles was not large, and the clouding slight, but where the valley air was greatly in excess, the number of particles was great, and the cloudexcess, the number of particles was great, and the cloudcess that the control of the control of the conditions in stratus and other clouds may be differed to ditions in stratus and other clouds may be differed for ditions in stratus and other clouds may be differed for ditions in stratus and other clouds may be differed for the conditions in stratus and other clouds may be differed for the stratus and other clouds may be differed for the stratus and other clouds may be differed for the stratus and other clouds may be differed for the stratus and other clouds may be differed for the stratus and other clouds as the stratus and other clouds and the stratus and other clouds and the stratus and other clouds and the stratus and other clouds are the stratus and other clouds as the stratus and other clouds are the stratus and the clouds are the stratus and the stratus are the stratus and the

During this visit to the Rigit there were a number of opportunities of investigating the water particles in clouds. The apparatus used was the small instrument described to the Society in May last. With this instrument the warmer for the state of the society of the state of the

few seconds the rate was much quicker. Though the quuck falls seldom lasted long, yet 30 drosp per sq mm per mutte were frequently observed for a considerable time. The maximum rate of 60 per sq mm per half minute gree 12,000 drops per square centimetre per families gree 12,000 drops per square centimetre per This does seem to be an enormoun number of drops to fall on so small an area in the time. These drops, however, are so extremely small they rapidly exaporate, more than two or three being seddom visible at the same me on one square of the micromiter. The denser the cloud the quicker was the rate of fall, and as the cloud duminished in size at the same time.

It was frequently observed when the mountain-top was in clouds, particularly if they were not very dense over-head, that the surfaces of all exposed objects were quite dry, not only the stones on the ground, which might have received heat from the earth, but also wooden seats, posts, &c, were all perfectly dry, and if wetted they soon dried. While everything was dry, the fog-counter showed that fine rain-drops were falling in immense numbers From the fact that the air was packed full of these small drops of water, it might have been assumed that the air was saturated, and tests with properly protected wet and dry bulb thermometers showed that it was saturated A few observations were therefore made to explain this apparent contradiction of surfaces remaining dry while exposed to a continued shower of fine rain and surrounded by saturated air The explanation was found to be, simply, radiant lieat Though the cloud may be so dense, it is impossible to see the sun or even a preponderance of light in one direction to indicate its position, yet, as a good deal of light penetrates under these conditions, it therefore seemed possible some heat might do so also A thermometer with black bulb in value showed that a considerable amount of heat penetrated the clouds under the conditions, as it rose 40° to 50° above the temperature of the air while the observatoons were being made. This radiant heat is absorbed by all exposed surfaces and heats them, while they in turn heat the air in contact with them, and the fine drops of water are either evaporated in this hot layer of air or after they come in contact with the heated surfaces Other observations made on Pilatus pointed to the same conclusion All large objects, such as seats, posts, &c., were quite dry in cloud when there was any radiation, while small objects, such as pins, fine threads, &c, were covered with beads of water. The large surfaces being more heated by radiation than small ones, when surrounded by air, these surfaces evaporate the drops falling on them, while the small ones, being kept cool by the passing air, are unable to keep themselves dry

The observations made with the fog-counter point to the conclusion that the density or thickness of a cloud depends more on the number of water particles in an othe number of dust particles in it is cloud system of the dust particles in the cloud's varied too much and too quickly to enable any conclusion to be drawn from observations made in clouds themselves. However, on comparing the thickness of a cloud on the Rigi and a fog at low level, when the number of waterdrops was about the same, it is found that the fog, though thicker, was not greatly so, although there were only a found that the housand dust-particles per cc. in the cloud, while there

were about 50,000 in the fog.

The observations with the fog-counter show that, whenever a cloud is formed, it at once begins to rain, and the small drops fall into the direr air underneath, where they are evaporated, the distance to which they will fall depending on their size and the dryness of the air. It is thought that much of the dissolving of clouds is brought about in this way.

NO. 1134, VOL. 44]

Abstract of Paper read before the Royal Society, Edinburgh, on July 6, by John Auken, F.R.S. Communicated by permission of the Council of the Soc etv.

OLD STANDARDS.

BY a curious accident it has just been discovered that the standard yard and certain other measures and weights which were supposed to have been lost when the Houses of Parliament were destroyed by fire in 1834 are still in existence The following account of the matter is condensed from a statement in the Times A reference to the contemporary records shows that after the fire the standard bars of 1758 and 1760 were both found among the runs, "but they were too much injured to indicate the measure of a yard which had been marked upon the measure of a yard which had been marked upon them." The principal injury to both of the standards was the loss of the left-hand gold stud, but whether this was caused by the action of the flames or otherwise is not known When the Palace of Westminster was rebuilt he two bars were deposited in the Journal Office, and from that time, until the other day, they seem to have been wholly lost sight of About a fortinght ago it happened to be stated in the lobby that one of the duties of the Speaker was to inspect once of the Lower Waiting Hall, Inquiries at the Standards Department of the Board of Trade elicited the fact that, so far from any statutory requirement being imposed upon the Speaker in the direction indicated, Section 35 of the Weights and Measures Act, 1878, which provides for the care and restoration of the Parliamentary copies of the Imperial standards, specially exempts the walledup copy from periodical inspection and comparison. It was found, however, that in 1871 Speaker Denison took cognizance of the standards, and this fact was brought to the Speaker's notice While inquiries were being made as to Speaker Denison's inspection, an official in the Journal Office mentioned that when the contents of that office were recently being transferred to the new wing he had observed among the lumber some old weights and measures. These proved to be the missing standards On Tuesday last they were examined by Mr Chaney, the Superintendent of Weights and Measures, and on Wednesday the Speaker was to visit the Journal Office for the purpose of inspecting them

The most important of the standards thus rescued

The imost important of the standards thus rescued from oblivion are the yard measures constructed by Bird in 1758 and 1760. The former was copied from a bar in the possession of the Royal Society, which was itself a copy of a standard preserved in the was itself a copy of a standard preserved in the district of the committee of the House of Commons from the 1758 standard. "Each of these two standard yards consisted of a solid brass bar 105 in square in section and 3973 in long. Near each end of the upper surface gold pins or studs of 101 in diameter were inserted, and points or dots were marked upon the gold to determine the length of the yard." The other standards in the custody of the Journal Office are two brass roads answering the description of the old Exchequer yard, and answering the description of the old Exchequer yard, and model, patterns, and multiples," ordered by the House on May 21, 1762, "to be locked up by the clerk and kept by him". The most important weight—the standard trop opinid—is not almost those now brought to light.

NOTES.

AT some little distance to the north and north east of Cardiff lies a heastiff piece of helly country, much frequented by pedestrans, and known as the Black Mountain or Black Fower district. It has not been fourd practicable by the Local Committee to arrange, an official excursion to this district on the occasion of the vith of the Bertish Association to Cardiffy, but a propert in pow being unofficially forwarded for conducting similar parties of not exceeding as a visitor each to some of the choicest

parts of the country, at a time so arranged as not to interfere with the sittings of the various Sections. Several local gentismen, throughly familiar with the dutrict, have offered to act as guides, and with fair weather most enjoyable excursions are to be anticipated. The country being essentially one for pedestrians, the excursions would take the form of an alternoon walk of from eight to twelve mides, with a further walk on the following days of from tweaty-five to turry mides. Any member of the British Association desirous of taking part in one of these excursions are an obtain full particularly by applying to the Local Secretaires, 9 Bank Buildings, Cardiff, who will forward the applications to the monoscier.

The annual meeting of the French Association for the Advancement of the Sciences will be held at Marseilles, commencing on September 17. The special subject chosen for discussion in the Botanical Section is the best mode of arrangement and exhibition for different kinds of botanical collections, with the double purpose of the preservation of the specimens and the facilitating of study.

The Technoal and Recreative Institute established by the Goldmuths' Company at New Cross was opened by the Prince of Weles on Wedensday In addition to this Institute there are to be two Polytechnics south of the Thames, one in Battersea Park Road, the other in the Borough Road The memorial stone of the one in Battersea was laid by the Prince of Wales on Monfay.

PROF M W HARRINGTON, the founder of the American Meteorological Journal, has been appointed Chief of the United States Weather Bureau, under the Department of Agriculture in Washington. Prof. Harrington was born in Illinois in 1848. and graduated at Michigan in 1868. In 1879 he was made Professor of Astronomy and Director of the Astronomical Observatory at Ann Arbor, Michigan From a recent article by him, entitled "How could the Weather Service best promote Agriculture?" it appears likely that the energies of the new service will be devoted more to the interests of agriculture than to commerce, and that an attempt will be made to issue special weather predictions for the farmer, by means of the multiplica tion of local forecasting stations There can be little doubtseeing the large amount of funds under his control-that he will also still further advance the important work of inter national meteorology which has been so ably conducted by his predecessor.

The balfyearly general meeting of the Scottish Metcorological Society was held in Edinburgh on Wednesday. The report from the Council of the Society was presented, and papers were read on certain relations of winds, pressure, and temperature at the Ben News Observationes, by Dr Buchan, and on influenza and weather of London in 1891, by Sir Arthur Mitchell and Dr. Buchan

FROM the official record of the work done in the British Museum during 1890 it seems that there has been a serious decrease in the number of visation. Special departments, however, have been used more than ever by students, and it is satisfactory to find that the zoological and geological collections in the Natural History Museum are being more generally appreciated.

GERMAN scientific papers record the death, on June 18, of Dr. Otto Tuchler, well known as an archeologist of wide learning and sound judgment. He especially distinguished himself by his investigation of the burni-mounds of East Prussla. Dr Tuchler was forty-eight years of age.

PROF. A. Riccò, Director of the Catania Observatory, who has just returned from a visit to the volcano Stromboli, sends us the following notice of a recent eruption .-- "On June 24, 45

minutes after noon (Rome mean time), the inhabitants of the Edolan Isles were shrared by two strong shocks of earthquake, followed by two tremendous explo sons of the volenno, which seat forth from four months a great quantity of made, cinders, incandecent blocks, and currents of lavs that descended the mountain slopes to the sea. The sea, at the points where the lave entered it, steamed up, producing great noisy masses of more returned to the sea. The office of the control of the season of the season

THE annual meeting of the Society for the Preservation of the Monuments of Ancient Egypt was held last week in the 100ms of the Society of Antiquaries at Burlington House. Lord Wharncilffe, President, occupied the chair The report stated that there was little to report of success attending the proceedings of the Society for the past year Its energies had been directed principally to two points-the necessity for an official inspector or superintendent in Egypt, whose duty should be the care of the ancient monuments, and an endeavour to do something towards arresting the gradual destruction of the Great Temple at Karnak Reports concerning a proposed scheme for barring the Nile below Phile, to make a vast reservoir for purposes of irrigation, had appeared in the public papers from time to time, and recently various more definite communications had been received by the committee on the same subject. The result would be, it was acknowledged, to completely cover this beautiful island and temple with water. There had been some correspondence on this subject with the authorities in Egypt; but as nothing had as yet been decided as to any scheme of irrigation, and as a committee would be appointed to consider the whole question. it might be considered as suspended for the present, and the committee had thought it hest to wait before taking any further action; but they would not lose sight of this important matter, and would oppose to the utmost of their power any engineering scheme which would involve injury or destruction to this worldrenowned spot. General Donnelly moved the adoption of the report; and the motion was seconded by Sir Edmund Henderson, and agreed to. The committee for the coming year was then elected, and a discussion subscouently took place as to the proposed scheme for barring the Nile below Phile, the opinion of the meeting being evidently strongly opposed to the adoution of any system of irrigation which should involve damage to the temple Mr J Bryce, M P , spoke of the wanton injury which was often inflicted on monuments in Egypt, and said that he thought it would be necessary, in dealing with that matter, to bring the question of jurisdiction to the attention of those from whom any system of inspection or care was to emanate. We may note that in answer to a question put by Mr. Bryce in the House of Commons on July 15, Sir J. Fergusson said that nothing definite had been settled as to the preservation of accient monuments in Egypt , £210,000 had been allotted in the Budget for the current year.

THE Pilot Chart of the North Atlantic Ocean for July contains a special account of a humanizan that moved along a track almost due north, about 500 miles cast of Newfoundland on June 9 and 10, together with a chart of the condition of barometer and wind between Newfoundland and Ireland, showing that the abnormal lanck was due to the approach of an anticyclone wert of the British Isles. A supplement sused with the Pilot Chart illustrates the drift of every bottle paper returned to the United States Hydrographic Office mose April 1869. There are 13 papers that contain the date makes April 1869. There are 13 papers that contain the date milles that each bottle drifted is 869, and the swenge daily drift is \$ 8 miller. This figure is rather below the true swenger size par day, as any time the bottle lay upon the shores before discovery added to its time of drift.

NO. 1134, VOL. 44]

M PATOUILLARD has just returned from a scientific mission with which he was intrusted by the Minister of Public Instruction in France, an investigation of the mycological flora of Tunis, Carthage, and the adjacent regions.

In one of the principal atticles of the Atterophysicale Zeitskry for May, Herr R Bornstein discusses the question of a connection-between air pressure and the hour angle of the moon, using as a hasty the hourly observations of four Gemma and Austran astations. This investigation differs from the usual mode of tectaments, as it takes no account of the moon's phase, or of its declination or distance from the earth, but only of the lunar day, and deals solely with aumospheric pressure. The results arrived at air. (1) that the easience of atmospheric tides is not planly recognished in the range of pressure, (2) at three of the planly recognished in the range of pressure, and three of the day. The maximum occurs at Hamburg and Breits shootly before the setting of the moon, and at Vienna about the time of the lower culmination, while the minimum occurs at all stations near the time of the moon soft range.

We have received vol. vii., of the Anales de la Operan Mateorologica Argentina I continus a summation of the records obtained at five different stations in the Republic during the years 1877-89 The organization of the Department appears to be now very complete, there being no less than twenty eight stations fully equipped with ordinary and selfregulering instruments

REFERRING to a statement which has been publicly made. that the adoption of electric lighting in place of gas at the office of the Savings Bank Department of the General Post Office has been followed by a marked reduction in the amount of sick leave, the Lancet says it has good authority for believing that the statement in question is substantially correct. Although the time which has as yet elapsed-two years -since the introduction of the new illuminant has been insufficient for the collection of trustworthy statistics, our contemporary thinks there is every reason to believe that electric lighting will prove to be much more wholesome than ordinary gas flames An electric lamp does not compete for the oxygen of the apartment in which it is placed, and this circumstance gives it a marked advantage over any open flame. It cannot, like some forms of gas-burner, be used to promote ventilation, but in ordinary situations its harmlessness is a much more important property

MELEOROLOGICAL Observatories are generally ill adapted, by reason of dust and sonce, for observation on atmosphere electricity, and, with the view of inciting private individuals to such work, Herren Elster and Genel, of Wolfenbuttel, have such work, Herren Elster and Genel, of Wolfenbuttel, have laiely issued a brockure in which they indicate the ends to be sought and the instrumental mean. Three things demand attention: first, systematic observation and measurement of electricity in the open art at different times in the day and in the seasons, himmidity and air-temperature being determined at the same time, second, measurement of the fall of potential with a clear sky; and third, measurement of the fall of potential and its change of sign during rain, &c. The instruments and methods recommended are such as present little difficulty for private persons.

THE American National Geographic Society prints in the current number of its magazine a full and interesting account, by Israel C. Russell, of an expedition to Moant St. Elias, Alaska. The paper is illustrated by various excellent maps and disgrams.

THE Winchester College Natural History Society has just smuch, under the title of "Geological Notes" (f Wells, Winchester), a list of all the fossils as yet known from the chalk in the antickinal of Winchester. The exact localities and zones are given, and, since the names appear not only to have been

carefully determined, but to be well up to date, this very modest pamphlet will prove as useful a guide to the collector as it is valuable to the stratigraphical geologist.

MESSIA WOUNGLI, MINSHALL, AND GO, Dowestry, have sixued "A Finn of O-westry and Darting," by T. P., Diamond, Honorary Secretary of the Offa Field Club. It contains a list of plants in the negleobarrhoos of Owestry, arranged according to their natural orders; and at the end there is an index, in which obth the English and the Wesh insues of the plants are given. Mr. Diamond calls attention to the dog out of the 10th and of the Wesh index of the plants are given of the state of the plants of the United Kingdom."

The United States Department of Agressiture is printing—in the series studied "Contributions from the United States National Herbarum"—what promises to be a valiable manual of the plants of the plants of Western Feas, by John M. Coulter. This district is described as "one of the richest regions in plant district, and for particularly interesting on account of the intermingling of Meascan species." The manual is being published in parts because the author's hopes this their wiscessive appearance may call forth additional information that may be embodied in a final turniformat.

A SHEAT dealing with the potato disease will shortly be issued by the Royal Agracultural Society of England. It was originally published by the Irish-Land Commission, by whose permission it is being reproduced. In the text, by Mr. William Caruthers, F.R.S., all necessity information it gives, and this is accompanned by coloured drawings illustrating various phases of the potato disease.

In the July number of the London and Maldites, Note-Disks, Mr. G. F. Lawence says he recently obtained a drill implement of unusual form from the site of Mr. Peter Robinson's new premises in Ochrol Street. The peculiarity consists of the carnous curvature of one face of the implement compared with the flatness of the other side. He does not know of another like it, but suggests that, as sitention is called to what may be a mere variation of an ordinary type, examples may be found in other collections. This specimen is of a somewhat ochross colour, is lativous and lost is glightly abrieded or rolled, and it measures §2 inches long by 3 inches wide. The occurrence of drift-implements in Central Londons is rather unusual. Mr. Lawrence thinks, twelve would be rather over than under the number known.

In the current number of the Scientific Proceedings of the Royal Dublin Society (vol vii Part 2) Mr E W L Holt publishes a preliminary note on the fish obtained during the cruise of the s s Fingal, 1890, on the Society's survey of fishing grounds on the west coast of Ireland Amongst the shore fishes, Aphia pillucida, Nardo, and Crystallogobius missonii, Dub and Kor are for the first time recorded from Irish waters The second British specimen of Arnoglossus grohmanns, Bonap , is also recorded. From depths between 100 and 500 fathoms off Achill Head, Pomatomus telescopium, Risso, Mora mediterianea, Russo, and Manurus aqualis, Gihr, are added to the British fauna, and a description is given of a new deep sea eel, intermediate between Saurenchelys and Nettastoma, which has been named Nettophichthys retropinnatus, n. g et sp. Gadus esmarkus, Nilsson, and Macrurus rupestres, Gunner, are added to the Irish fauna from similar depths, and Argentina sphyrana, Linn., from 52 to 80 fathoms. Amongst other fish recorded from depths exceeding 100 fathoms are Chimara monstrosa, Linn , Trigla lyra, Inn , Gadus argentens, Guich., Phycis blenmoides, Brunn. Halopor therus eques, Gthr., Macrurus calorhenchus, Risso, M. lavis, Lowe, &c A young Phycis is also recorded from 26 fathoms, and mention is made of the occurrence at the

surface of a shoal of young Gadus poutassou, Risso, 34 miles from land.

HARDWESS a one of the most important properties of solid boties, yet the measurement of it has not been very astifactorily effected hitherto. Frof Auerbach, of Jena, has recently described (Réviensum fur Payars) an apparatus for the purpose, designed for transparent bodies. In it the spherical surface of a lens a present up by the bort arm of a weighted lever against a small thick plate, on which the observer looks down though a merconcepe furnished with a microniver, withdrawn the effects of increasing furniture. The properties of the the effects of increasing furniture to the subject, and test if A comparison of hardnesses with models of elasticity shows that, while the more elactic of those substances were also the harder, the hardness microxies less than the elasticity

FAON recent accounts at appears that the consumption of gas in Parin in 150 occeeded that in 180 by 36 3 per cent, while the number of consumers increased 56 Spire cent. The amount per consumer discussed 156 Spire cent. The amount per consumer discussed 150 Spire cent. from 1642 to 1322 calube metres. Electricity has evidently withdrawn many large consumers of gas. The same account states that in Ariser years the number of are and glow lamp shis increased 44 quantity of the consumption of periodium in France has moreased 47 per cent in those ten years, while that of gas, in the whole of France, has grown 62 per cent.

A statis of addition compounds of alchylics with hypophophorous such an described by M. Ville in the current number of the Annales di Chinus et de Physique. As is well known, adebythe schulit the characterium property of uniting directly with inany other substances, such as ammonia, hydrocyanic acid, and sulphies, and hydrocyanime Some time ago, it was shown by Foosek that truchloride of phosphorus was likewise capable of nuting directly with many alchelydes with production of liquid compounds decomposable by water M. Ville now show that a sunfair ternet of additive compounds are formed with hypophosphorous acid, and these compounds are of conditional control of the condition o

action of aldehydes under the influence of a slight rise of temperature, two distinct classes of new compounds are obtained. When the aldehyde and hypophosphorous acid are allowed to react in the proportion of equal molecules, compounds of the R-CLI-OH

type PO-OII are obtained, where R may represent the

are formed. The aldehydes of the aromatic series lend themselves best to the formation of these compounds, those of the fatty series exhibiting a great tendency to the production of condensation products The compound of the second type with C2H.—CII.—Oil

benzoic aldehyde, PO-OH, is obtained by digesting to-

gether for several hours upon a water-bath bennaldehyde and hypophosphorous acul man attausphere of carbon disoxde Crystals of the new compound soon commence to separate, and repully permeate the whole liquid On draining and washing, they are found to consust of colourleus radiating groups of lamelle. They are not very soluble in water, but disolvie more readily in organic solvents, best in methyl alcohol. The aspects obtains a strongly acud, deconpoung exchanates readily, and forming crystalline salls with base? Currous phosphorous control of the control

In order to obtain the acid of the first type, PO-OH,

it is bet to employ an excess of hypophosphorous and In this case, instead of cytals of the nad of the second type separating, the whole forms a homogeneous liquid which remains unpre-cipitate by water Ir contains the each of the first type, and this latter is best in later by precipitating by water in contains the each of the first type, and addition of lead scente and decompoung the salt, suppended in water, by means of sulphuretted hydrogen. On concentration of the filtered solution, a syrup is obtained which eventually yields deliquescent crystals of the pure acid. The solution plant is not the solution of the filtered solution, a syrup is obtained which eventually yields deliquescent crystals of the pure acid. The solution of this nord does not reduce copper sulphate, but readily precipiate-metallic silver from silver nature. Many similar compounds with other additionals have also been prepared, and found to present analogous properties more or less modified by the specific nature of the particular additivity deep employed.

This additions to the Loological Society's Gardeas during the past week include two Raddy-headed Genet (Bernaile ratiolatery) & form the Falkiand Islands, presented by Mr. F. L. Blauwy, C. M. Z. S., a Smooth Sincke (Cornealla Levil), British, presented by Mr. W. H. B. Pain, two great Eagle Owis (Bibbo) measures), European, depotude, as K. Syed. Lizards (Laceria cellitals), two Four-lined Snakes (Caladre yaudstineatist), a Rack-marked Sakes (Rinnerks scalars), South European, purchased, a Burshel Wild Sheep (Owis burshel d.), a Ipanese Deer (Cervan Link P), a Bennerit Wallaby (Edmadarusa tennatis V), two Night Herons (Nycticeras griseus), bred in the Gardens.

OUR ASTRONOMICAL COLUMN.

A CAURE OF LUNAR LISBATION —A paper by Mr. S. E. Peal, "On a Powible Cause for Lunar Libration of her than an Ellipsoidal Figure, and on Lunar Snow Mountains," has recently been published by Mears Dulian and Co. It is shown that a been published by Mears Dulian and Co. It is shown that come the property of the proper

THE RECENT EPIDEMIC OF INFLUENZA.

THE morally in London from influents shore a Stady of decline work by week, and, although the number of dealbs in still in excess of the average, there are good reasons for hoping that the epidemic will shortly desappear from our midst. The seventy of the recent viviation, as compared with that which presulted into year, in clearly shown by the are displayed slide by nice. The weekly morality from influents alone is represented by the third curve, the number of deaths

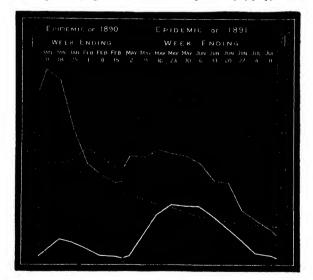

from diseases of the respiratory system by the lighter curve, and the average number of deaths from disorders of the latter class by a dotted line. The average mortality from influenta is too small to permit of any curve being drawn upon the scale shown in the diagram.

in the enagram. Taking into consideration, firstly, the mortality from influenza slone, we find that not only was the duration of last
year's pedieum far less than that of the present year, but that
the number of deaths in the earlier period was very much smaller
than in the latter. The epidemic of 1850 set in with great
severity and suddenness at the beginning of January. During
the week ending December 28, 1889, there were no deaths in

the epidemic prevailed with more or less severity, it appears that the total number of deaths in London was 442, giving an

that the total nomber or centra un Lousou was 444, grangs average of 7, per week.

The vastation of the present year may be said to have commercial at the beginning of May. During the whole of April mercial at the beginning of May. During the whole of April weeks embraced by the Reguttra-General's returns being respectively 7, 3, 9, and 10. By the week ending May 2a, however, the number had risen to 37, and from this time conward the disease continued to spread with alarming rapidity, the numbers in the three successive weeks being 148, 266, and a maximum during the week ending May 33 of 319 In the two

London from this disease, and in the following week only is to the week confing fanary 1, 1850, however, he number had risen to 57, while in the course of the ensuing seven days a metallic three transitions of 127 was reached. The mortality then declined stradily, the numbers in the four succeeding weeks being respectively, 105, 75, 58, and 30, 48 a serious spedentic the restriction may then be regarded as having spent itself, and in include any period in which the weekly number of deaths fell below 25. It may, however, be remarked that, for three week subsequent to that shown by the curve, the mortality exceeded 20, while in the four succeeding weeks it ranged between 20 and 37 Taking as v whole the period of an weeks in which

ollowing weeks the mortality spain exceeded too, after which it and ecclined steadily to ago, 183, 117, and 56, while in the hast period shown by the diagram the number had fallen to a faing the period show by the diagram the number of deaths in London Taking the period as a whole; it appears that dramp the eleven weeks exding July 11 the total number of deaths in London to the period of the control of the state of the control of the state of the control of the state of the control of the control

From an examination of the statistics given in a valuable

paper read before the Scottish Meteorological Society on March 31, 1890, by Sir Arthur Mitchell and Dr Buchan (an abstract of which appeared in NATURE, vol xl., p. 506), it is quite evident that the recent epidemic of influenza has been the most severe we have that in London since the first publication of weekly severe we have had in London since the first publication of weeking records of mortality some forly-five years ago. As the figures are of great interest, we make no apology for reproducing the brief table given in that paper, showing the number of deaths which occurred in the five principal epidemics experienced uncet the year 1847. It will be observed that the number given for last year is considerably in excess of that quoted above, the period selected by the authors of the paper comprising the whole of the three months January to March In the month last menof the three months January to March In the month last men-tioned, the epidemic was certainly not of any great severity, but as the figures do not clash in any way with the general argu-ment, I have not thought it advisable to alter the results An addition has, however, been made to the table, by including the figures of mortality reached during the epidemic of the present

December 1847 to April 1848 .	Death 163
March to May 1851 .	251
January to March 1855	130
January to March 1855 November 1857 to January 1858	12
January to March 1890 May to July 1891	54
May to July 1891	202

It will be seen from the table that the mortality recently experienced has been far greater than at any other period during the forty-five years, the nearest approach to so severe an epidemic being in 1847-48, when the deaths amounted to about 400 less Taking into consideration the fact that the population of London As years ago was very much smaller than it is now, it may at the first blush appear that, as regards severity, there was not very much to choose between the two visitations. It must not be forgotten, however, that in the earlier period the ravages of the disease extended over five months, while in the latter

they were confined to about two and a half

they were confined to about two and a hair.
A very striking feature in the disease to which the somewhat
militeding name of influenza has been given, is its peculiarly
weakening effect upon the lungs and bronchial tubes, and as the
epidemic is invariably attended by a high mortality from respira-tory diseases. I have included in the diagram a sense of curves
showing the number of deaths from these attendant disorders. showing the number of central from these attendant cuspruers. As regards the epidemic of 1890, it may at once be confessed that the curve is somewhat misleading. During the last few days of 1889 and the opening of the following year a sharp touch of anticyclonic cold was experienced over England, and in the metropolis this was accompanied, as is so commonly the case, by thick fog Under such circumstances a high mortality from respiratory diseases followed as a matter of course, so that when we examine the curve we find that, at the time when the epidemic of influenza was only just appearing, the deaths from lung dis-orders were at their maximum. After the first week in lanuary, however, the weather became unusually mild for the time of year. a long period of south-westerly winds setting in, with abnormally high temperatures. There can be little doubt, in fact, that at the nign temperatures, asser can os entre count, in act, max at me time the influenze apodemic of \$500 was raiging the effects of tem-perature and weather were so strong as 10 obliterate the influences of the mismatter disorder upon diseases of the respiratory amount be eliminated from second, methodological element may almost be eliminated from second, published old winds were second to the source of the second of very frequent in May and the early part of June, the severity of the weather was not such as to lead to any material increase of the weather was not such as or sear to any manerial increases or individually from the class of diseases in question. The spread of influenza was, however, soon followed by a serious rise in the death-rate, and in the course of the fortnight ending June 6 the

destinate, and in the course of the featingle ending. June 6 the mortality from respiratory compliants amounted for more than twice the average, the large excess bring due chiefly to death from pneumona and bronchils. The subsequent decline of in-flering a was accompanied, as will be seen from the curve, by a stream of the second of the contract of the course, but a twan not until the last week of the period fast produces, but short of the average. Taking the eleven weeks as a whole, it appears that the total mortality from respiratory disorders amounted to 5136, or about 75 per cent. more than the average During the epicienic of 1000 the acount number was far larger, and as a matter of fact the excess above the normal onlymmounted last week to 26 per cent. The Report of the Committee appointed to consider the aestion of securing the aid of specialists. The meeting was eminently pleasant and successful, thanks to the untiring energy and evertions of the President and of Mr. S. F Harmer (Fellow of King's College), the Local Secretary and r riarmer (reilow of King's College), the Local Secretary and Treasurer. Under their guidance several colleges, thoranes, and laboratories were visited Prof Middleton conducted a party over the Fitzwilliam Museum, and, through the kindness of Prof. Newton, a few of the members visited the Pepsian

The influence of the weather upon the two enidemics seems to I he immence of the weather upon the two epidemics seems to have been exerted in entirely opposite directions. During the epidemic of 1850 temperature was, as we have already seen, for the most part very high for the time of year, and the pre-valence of a strong current of south westerly winds in January doubtless added in the dispersal of the measmantic germa. The weather was, in fact, as favourable as could have been desired, and weather was, in fact, as involved as could nave need cearriest, and the ravages of the epidemic, severe though they were, were doubtless much milder than they would have been had the winter heen cold and foggy. The recent epidemic has not had so many foes to contend with, for in the carrier stages of its career the weather was not only cold for the time of year but also calm and quict. The germ was therefore able to settle in our midst without serious opposition, and the ungenial nature of the atmosphere has doubtless been responsible for much of the lung and bronchial disease which has followed in its train Deluded by the knowledge that the spring season was upon us, and forgetful of the fact that it had come in an unkindly guise, many a weakly convalescent has been emboldened to venture out into the chilly air. and has contracted a serious cold, from which in too many cases he has been unable to recover. FREDE L. BRODIE.

THE MUSEUMS ASSOCIATION

THE Museums Association held its second annual meeting in Cambridge on July 7, 8, and 9, under the presidency of Mr John Willis Clark, Superintendent of the Museum of Zoology and Comparative Anatomy, Cambridge, and Registrary of the University.

The following representative of Mixeums (outside Cambridge) and associates were present —The Rev H. H. Higgins, Mr. R. Paden (Liverpool), Mr. R. Cameron, Mr. I. M. E. Bowley, Standerland), Mr. G. R. Bothers, Mr. J. W. Cerr (Notting-ham), Mr. Councillor I. Burt, Mr. J. Pacon (Giasgow), Nr. Stockport), Adderman W. H. Brittian, Mr. F. Howarth (Sheffield), Mr. Joseph Clarke, Mr. G. N. Maynard (Saffrod Mysiken), Mr. S. Washerman, W. H. Brittian, Mr. F. Howarth (Soffield), Mr. C. Madeley (Warrington), Mr. I. Lyon, Mr. J. J. Del (Bodtel), Mr. W. E. Holye (Deven College, Manchester), Mr. H. M. Patanseer (York), Mr. F. W. Radder, Mr. F. A. The proceedings were opened by the Rev. H. H. Hierons. The following representatives of Museums (outside Cambrid

Bather, Mr. A. Smith Woodward
The proceedings were opened by the Rev. II. H. Higgins
[Past-Fre-ident), who introduced the Fresident, Mr. J. Willis
Clark. The Fresident then read his address, and gave a short
and very interesting account of the early history of Cambridge
and of the foundation of a few of the older Colleges. On the 8th and 9th the following papers and reports were read and ducussed

- "On some old Museums," hy Prof A Newton, F.R S,
 "On the desirability of exhibiting, in Museums, unmounted
 skins of birds," by the Rev II II Higgins "On difficulties incidental to Museum demonstrations," by
- F. W. Rudler. "On the Dresden Museum cases," by Dr. A. B. Meyer,
- "On the registration and cataloguing of Specimens." by W E. Hoyle
- "Some recent Museum legislation," by E Howarth
 "On the arrangement of Rock Collections," by I
- Platnauer "Fossil Crinoidea in the British Museum" (an attempt to out into practice modern ideas of Museum arrangement), by F.
- Bather.
 "On Tables and Chairs," by F A Bather.
- The Report of the Committee appointed to consider the question of labelling in Museums

TECHNICAL EDUCATION IN INDIA.

CIR AUCKLAND COLVIN, the Governor of the North-Western Provinces of India, has issued an exhaustive minute on technical education in that country, in which the various steps towards the introduction of this system of instruc tion are summarized. The minute naturally refers chiefly to the North-Western Provinces, but is in fact a summary of what has been done elsewhere. It seems that the idea of introducing technical education in the North-West Provinces, where their has hitherto always been a steadily increasing demand for University education, was first mooted in September 1885, when the attention of the local Government was called to the Madrae the attention of the locks coveriment was saired to the examination, scheme, which aimed at promoting instruction in industrial arts and manufactures by offering grants in-aid to encourage the teaching, in schools so aided, of technical science, arts, and handicrafts, and by testing that teaching by a system of public examinations. Nentry a year later the Home Secretary to the Government of India drew up a note on the subject generally, pointing out that there was room for improvement in this branch of education in the great north-west, and inquiring what was being done. The Director of Public Instruction replied that the question of establishing Faculties of Medicine and Engineering was under consideration in the Allahabad University, and ing was under consideration in the Aliahabad University, and also certain perparatory courses of study, while it was proposed about certain perparatory courses of study, while it was proposed Local Records Department. In January 1888, Colonel Forbes, replying to questions addressed to him regarding instruction in engineering, said he considered that the practical instruction gained by nature in the large railway workshops at Allahabad, Lucknow, and Labore, and at the Government workshops at Euckniow, and Layore, and at the trovernment workshops at Roorkee, was decidedly bearing fruit in the direction of enabling natives to take intelligent and independent control in these branches of technical industry. The railway and Government workshops he considered were the real technical schools so far as workshops he considered were the real technical schools so far as that branch of instruction was concerned, and there was no need, therefore, for the Government to establish itschined and the state of though such opportunities need only be limited in number. "For the higher grades of engineering. I thank the ordinary liberal education with a scientific knowledge is most suited, until a man is of an age to know his mind, and elect for the profession, when there should be a strictly technical education for a limited time, two or three years, followed by a careful apprenticeship on works." The late Colonol Ward contended apprenticeship on works." The late Coionci ward contended that facilities should be given at the Roorkee College for practical instruction, in addition to the present theoretical course "If such a technical practical class were formed at Roorkee, students from the schools might be allowed to attend it without going through the College theoretical course." on, the Director of I and Records and Agriculture sent in an opinion on the subjects immediately referred to him, and advocated nothing more than the creation of a normal school for survey only, at Cawnpore or Lucknow, suggesting also the establishment of small scholarships for the maintenance of boys in training at the various workshops in the provinces; of an art school at Lucknow, and of agricultural and veterinary schools or classes in high schools, and he proposed that drawing should be made compulsory, competency to teach drawing being pre scribed as an essential qualification in all teachers in middle and high class schools. And finally, the Inspector-General of Civil high class schools. And many, the inspector-teneral or civil Hospitals reported against the proposal to teach up to a higher standard than that of the hospital assistant class. Then, in March 1888, the Director of Public Instruction forwarded a second report adverse to the establishment of a school of art at Lucknow, and pointing out further that, however desirable was the proposal to introduce drawing into public schools, there were no funds available for the purpose. At the close of the year the prector forwarded a resolution, on the part of the Senate of its Allahabad University, to the effect that any steps to establish a College for training medical practitioners would at precent be premature. At this point, says the Times of India, in discussing Sir Auckland Colvin's minute, the cold water current ceased. In the February of last year the Director of Public Instruction

forwarded a mutute by the Allahabias I censte, it which it was decirated to establish a Faculty of Engmenting, degrees burge conferred on men who had passed at least a three years theoretical connex at a properly constituted. Engmenting College or school. The property of the stable to grapher, the only place at which engineering can be tautied in the North-West Provinces in Roorkee. The Public Works Department, he adds, so of opinion that if degrees are to be conferred by the Allahabad Unremy the Konkee certificate be conferred by the Allahabad Unremy the Konkee certificate benefits of the property of the property of the property of the Control of the Comment. Then the establishment by the University of a special examination of "a connecreal and training class for technical electation, still remain under consideration. The general conclusion, Str. A. Colvin thinks, as the, on the whole, opinion points to onlying more suggest or obtaining instruction in the salicoritistic grades of practical engineering, and in the handsterf of the artists. Str. Auckland Colvin then sums up the subsequent papers on the subsect, relating to the offer of the British Indian Association in 1978, a 500 per month, a school of industry in one of the Wingfield Manali subsequencing, reaching & 17,440 per anisom, to the offer of the British Indian Association in definition individual subsequency, reaching & 17,440 per anisom, to the drivated by the British Indian Association in definition of the warded by the British Indian Association in definition of the warded by the British Indian Association in definition of the warded by the British Indian Association in the dark and forwarded by the British Indian Association in the dark and the contraction of the British Indian Association in the dark and the contraction of the British Indian Association in the dark and the contraction of the British Indian Association in the dark and the second of the second of the second of the seco

Sir Auckland next devotes himself to a consideration of the systems of technical instruction at work in Bombay and Bengal. systems of technical instruction at work in Bomony and Bengai. From a careful study of the facts and the more or less volumin us papers in which they were originally enshrined, he proceeds to define what is meant by technical education so far as at is applicable to the North-West Provinces. Technical education in Europe he illustrates by Mr Scott Russell's words . "It is necessary that each individual shall, in his own special profession, trade, or calling, know more thoroughly its fundamental principles. wield more adroitly its special weapons, he able to apply more skilfully its refined artifices, and to achieve more quickly and economically the aim of his life, whether it be commerce, manufactures, public works, agriculture, navigation, or architecture;" and by an extract from Mr. Kirkham's report, in February 1889, to the Bombay Government "The general principles that the shops are only called into existence by capital operating in ac-cordance with its own law—that this training, so far as it can be cordance with its own law—that this training, so far as it can be given in schools or colleges, must be, in the main, preparatory and disciplinary, and that is improvement of science teaching are the indepensable perluminates of any form of practical training. It is those to the indepensable perluminates of any form of practical training. It is those to the main the indepensable of the matter is concerned, directly they come to the practical details there is, as Mr Kirisham admits, every to the practical details there is, as Mr Kirisham admits, every the control of come bound designed to the present of the property sizes in 10 come bound of the control of the present of th in a way to differ from every other system, just as the leading industries of different districts differ Apart from this, however, industries of different districts differ Apart from this, however, the Bombay ystem was found to be far too elalorate for the North-West Provinces From Bengal Sir Alfred Croft wrote a very practical and sensible letter, condemning the abolition of the Seebpore workshops, and urging that the primary point, so far as engineer students were concerned, was to learn how to use their hands He also quoted Mr Spring, who says there can be no question as to their superiority for public works employment if the men have gone through the course of manual training.
"An engineer who has learned to use his hands is, other things being equal, an all round better and more useful man than one who has not "Sir A Croft goes on to further condemn the neing equal, an air round better and more useful must train one who has not: Sir A Corf goes on to further condemn the removal of the Scebpore shops from the point of view of the need of the mechanic class. "It may be freely admitted and taken as proved that the maintenance of the shops is undestrable from the point of view of the Public Works Department. But it is no less clear to me that the interests of that Depart-But it is no less clear to me that the interests of that Depart-ment are in this matter antagonist to those of technical educa-tion; and that the deliberations of the Committee large been chefly governed by regard to the former. The Gorgianems, however, remained in principle annoved; but happily in practice they agreed with the Director of Public Instruction, and the Government of India followed suit; thus establishing a very important principle in regard to technical education. Armed with all this experience, and conceding for the moment the

existence of a demand for men competent to deal with machinery and familiar with all the lower forms of engineering, Sir A. Colvin proceeds to discuss what course the training should take, how best to secure it, and the sources from which the necessary funds could be obtained. With regard to the first point, he thinks that what would mostly he required are facilities for gaintnins mat what would make a protectal knowledge of the more and a protectal knowledge of the more sary to a foreman mechanic, more especially in connection with the steam-engine, the railway workshops, and the ron foundry, and also of the processes of cotton-spinning as employed in the mille established in the North West Provinces. "These are the two great branches of industry which in Bombay have been recognized as fields for native labour which, though in a lesser degree, exist here (in the North-West Provinces), and in regard to which, at present, specialized means of instruction are unquestionably, in these provinces, wanting "With regard to the second point, there exists at Roorkee a Government Engineering College and Government workshops, and it seems probable that these will form the nucleus of the instruction necessary As to the third point, Sir Auckland Colvin thinks it would be premature to enter into the question of funds until the dimensions of the scheme are definitely decided upon—Finally, to see how far all these views meet the industrial needs of the province. Sir Auckland has decided to seek the aid of a strong Committee, which will obtain from all available quarters information on the points indicated in the minute, deputing members to Calculta, Bombay, and Madras, and subsequently reporting to Covernment the result of its inquiries, with its own recommendations, and with full details of any scheme which it may desire to see carried into effect

SOCIETIES AND ACADEMIES LONDON.

Chemical Society, June 18-Prof A Crum Brown, F.R.S., President, in the chair - The following papers were read -A note on some new reactions of dehydracetic acid, by read —A note on some new reactions of dehydracetic acid, by pass ing chyl aceto acetate brough a red hot tube, it is stated that alcohol is formed, the author finds that large quantities of ethylene gas and acetone are also produced. Dehydracetic acid, had so volatite to a considerable extent with steam, and is decomined. posed by boiling with water to a small extent into cerbon goed by Johnig with water to a binal extent into carbon dioxide and dimethylpyrone This latter decomposition is more readily effected by boiling the acid with strong hydro-chloric acid. If 50 grams are boiled with ordinary funning hydrochloric acid, the whole is converted into carbon dioxide and a soluble compound of dimethylpyrone with hyllrochloric acid. and a soluble compound of dehydractic acid, $(C_1H_0Q_1)B_1$, seems to be not a sair of the compound $C_2H_2Q_2$, but of the true tetracetic acid, $(C_1H_2Q_2)B_1$, as seems to be not a sair of the compound $C_2H_2Q_2$, but of the true tetracetic acid, $C_1H_2Q_2$. A very stable copper sait of the formula $C_2H_2Q_3$, D_1Q_2 is obtained if dehydracetic acid be added to a solution of copper acctate in a large excess of

nonts -The lactone of triacetic acid, by Dr J Norman In a former paper on the constitution of dehydracetic acid (Trans Chem Soc, 1890, 189) the author pointed out that if the formula which he proposed for dehydracetic acid was correct it would be the 8 lactone of tetracetic acid. And the correct, it would be the 8 lactone of terracetic acid. And the following list was given showing the connection between the condensed acids formed from acetic acid. CH₂CO (CH₂CO), CH₂CO (H₂CO), tetracetic acid. CH₂CO (CH₂CO), triaccite acid. CH₂CO (H₂CO), triaccite acid. CH₂CO (H₂CO), triaccite acid. CH₂CO (H₂CO) acetic acid. At that time no acid corresponding to the triacetic lactone of this acid by the action of 90 per cent sulphuric acid on dehydracetic acid at a temperature of 130°-135" on dehydracetic acid at a temperature of 130°-135°. The proporties and reactions of the new compound are described—
The refractive power of certain organic compounds at different temperatures, by Dr. W. H. Perkin, F.R.S. The magnetic relations of sulisiances when examined at temperatures wide relations of substances when examined at temperatures swite aparts show that certain wratteness take place after allowing for any analysis of the refractive power of liquids under similar circulamstances. The results show that the specific refractive power is not contact for all temperatures. By comparing the lines A and F. it was found. that the dispersion was slightly diminished by rise of tempera-

ture The results were calculated by the formula $\frac{\mu-1}{d}$ When calculated by Lorentz's formula: the numbers gave higher results for high temperatures than for lower ones. Sive on a value for high temperatures than for lower ones. Sive one as value for high temperatures that the same properties of the same properties of the same properties. The formation of salls, a contribution to the theory of electrops and of the nature of chemical change in the case of non-electroptes, by 11 b Armstrong. The author draws attention to the recreat researches of Glassen, W. Wallectras, and others, which clearly show that ethereal salts form compounds with sodium ethylate, and to the bearing which these results have on some envisace, and to the bearing which there essents have on the theory of the formation of salts generally. It may be sup-posed that the ackl and the "base" in the first instance com-line, and that the salt is formed by subsequent interactions within the molecule. In like manner, acids form dissociable compounds with water, and by the occurrence of change within compounds with water, and by the occurrence of change within such systems, under the influence of electromotive force, electro-lysis is effected. When the compound is highly unstable, the opportunity for change within its system is alight, the acid is a week one, and its solution of relatively low conducting power. In the case of non-electrolytes, the occurrence of change may be In the case of non-electrojytes, (no occurrence or change may one supposed to occur within complex systems formed by the union of the interacting substances—Dibensyl ketone, by Dr. S. Vonng. The author finds that, in preparing the ketone by heating calcium phenyl acetate in a combination furnace, only 27 per ceni of the theoretical yield in obtained. However, if 27 per cent of the incording yield is obtained. However, if the calcium sail be heated by means of the vapour of boiling sulphur, the yield of pure ketone amounts to 76 6 per cent.—

The vapour pressures of dibenryl ketone, by Dr. S. Young —

The vapour-pressures of mercury, by Dr. S. Young I wo additional observations of the vapour pressures of mercury at 183° 75 and 236° 9 have been made, and, from the previous results of Ramsay and Young, the boiling point and the vapourpressures of mercury have been recalculated

prevares of mercury have been recalculated June 25.—Extraordinary General Meeting —At the request of cerian Fellow, to the President, an extraordinary general meeting was summoned to consider a proposal for amending and altering the by-law. The proposal was moved by Mr. James Wilson and seconded by Dr. Teed Mr. Castriphe moved the following amendment. "That this meeting declines to pledge itself to any amendment or modification of the by-laws which used to approximate the constitution of the by-laws which the present the constitution of the present constitution of the by-laws which the present the constitution of the present constitution of the present the present the constitution of the constitution of the present the present the constitution of the constitution of the present the present the constitution of the constitution of the transfer of the constitution of the constitution of the transfer of the constitution of the constitution of the transfer of the constitution of the constitution of the transfer of the constitution of the constitution of the transfer of the constitution of the transfer of the transfer of the constitution of the transfer of the constitution of the transfer of the constitution of the constitution of the transfer of the constitution itself to any amendment or modification of the by-laws which his not been approved and recommended to the Fellows for adoption by the Council." Sir F. A. Abel seconded the amendment Mr. Cassell, Mr. Lloyd, and Dr. Newton spake in favour of the original motion. Prof. Tilden, Mr. Warington, Mr. Page, Dr. Odhing, and Mr. Friswell spoke in favour of the amendment was carried by 137 votes to 47.

THE HISTORY OF CHEMISTRY

A History of Chemistry from the Earliest Times to the Present Day. By Ernst von Meyer, Professor of Chemistry in the University of Leipzig. Translated by George McGowan (London: Macmillan and Co., 1891)

F all branches of natural science, none has a history more profoundly interesting or more fascinating than chemistry. And yet, strange to say, none has received less adequate treatment from the historian The reason for this comparative neglect is not far to seek. The historian of science must have qualifications which are rarely united in one man: not only must be possess the attributes of the successful writer on social, political, or economic history, but he must also be a past-master in the special branch with which he deals, and be well informed on all its cognate branches. Germany has given us the classical volumes of Kopp, from France comes the learned work of Hoefer; whilst in England we have had, until quite recently, to be content with the somewhat trivial, disjointed, and partial narration of Thomas Thomson In addition we have had a number of monographs, especially within recent years, on the labours of particular individuals; many of these, like Henry's "Dalton," Wilson's "Life of Cavendish," Bence Jones's "Life and Letters of Faraday," and the remarkable series of biographical sketches which we owe to the facile pen of Hofmann, are delightful works, but these, after all, are only mêmoires pour servir As a rule, the more formal and general histories which deal with the organized growth of the science are not very attractive; either their authors lack literary grace and charm, or they are superficial, ill-informed, and, in some cases, so obviously biassed as to render them altogether untrustworthy. And, moreover, not one of them has sought to grapple with the splendid achievements of the last halfcentury in any truly philosophic manner. Kopp and Hoefer have, between them, told us all that is known, or, in all probability, ever will be known, or need he known. respecting the beginnings of chemistry, and of its growth through the Middle Ages, and down to the end of the last century We now require somebody to set about doing for this nineteenth century what the German and French historians have done for those that precede it. The labour would be stupendous, but the result might be magnificent. At no period in the history of the science have its generalizations been more brilliant, and its theories more comprehensive, more prolific, and, it may be added, more securely established The birth of the century saw the extension of the atomic hypothesis to the explanation of the fundamental facts of chemical combination, and it has been the chief and most characteristic work of the century to place that theory on a foundation as sound and as firm as that on which the immortal conception of Newton is based. The historian of the chemistry of the nineteenth century need have no other text than that of the atomic theory; for round this dominant conception all other present-day theories are

ranged; it is the centre of a system which it vivifies and feeds, and by which it itself is fed and strengthened in return.

Some attempt at what is here foreshadowed has been made in the book before us, but, excellent as the work is in many respects, it is even more suggestive of what remains to be accomplished. The book is divided into six chapters, of which the fifth and sixth are devoted to the history of chemistry from the death of Lavoisier to the present time, and these two chapters occupy nearly threefourths of the volume This portion is not only the larger, but is confessedly the most difficult of the whole In weighing and criticizing current chemical doctrine. and in discussing the theories of the present, even the most conscientious historian is apt to be unconsciously biassed by the predilections and prejudices of his training and environment. Prof. von Meyer has not been unmindful of this possible danger, but after carefully reading his work we can heartily congratulate him on the success with which he has preserved the "objective attitude" which is essential to the true historian. As he tells us, it has been his earnest desire to shed a clear light upon the conflicting views respecting the development and importance of the chemical doctrines of to-day. and to endeavour to apply a calmer and juster criticism to the services of eminent investigators of quite recent years than has hitherto, in many cases, been meted out to them It is possible that we apprehend Prof von Meyer's meaning the more fully when we state that such a catholicity of sentiment and so judicial a temperament have not always characterized the occupant of the Chair of Chemistry in the University of Leipzig

For the two chapters which treat of modern chemistry we have nothing but unqualified praise, and we earnestly commend them to the attention of those students who desire to have a coup d'aul at once comprehensive and accurate of the meaning and tendency of present-day doctrine. When we have regard to the enormous mass of material which has to be systematized, and, as it were, brought within focus, some errors and omissions are inevitable. And it is possible that here and there a slight lack of balance and due proportion may be discerned . some matters have been treated at comparatively great length, whilst others have been but scantily noticed this point differences of opinion are sure to arise tot homines, tot sententice But no candid reader can fail to be impressed with the singularly fair and impartial manner with which Prof von Meyer has dealt with the labours of contemporary workers. It is a pleasure to read a work in which the writer has been superior to the petty Chauvinism which has disfigured certain historical productions of the last twenty years We would specially indicate the critical notices of the labours and services of Lavoisier, Berzelius, Davy, Dumas, Liebig, and Wöhler, as models of historical acumen, sound judgment, and rigid candour. On the time-honoured question, "With whom should rest the merit of the discovery of the composition of water?" Prof. von Meyer is scrupulously just and impartial. He shows that Lavoisier was so far dominated by his principe oxygine ou acidifiant that, in burning hydrogen, "he expected to find an acid as the product of its combustion, and therefore looked for one. It is the undisputed merit of the phlogistonist Cavendish to have

proved that water alone is produced by the combustion of hydrogen" (pp. 157-58).

Although he devotes only two chapters to it, it is obvious that it is the main purpose of Prof von Meyer's work to trace the development of chemistry from the downfall of phlogistonism onwards, and he has therefore only dealt with the earlier periods in order to give the reader a connected view of the growth of the science. This portion of the work is touched with a comparatively light hand, and in some respects compares unfavourably with the rest. Although at times there are graphic sketches-as, for example, in the account of Palissy's work, and in the estimate of Bergmann's services to analytical chemistry, and in the story of that strange compound of truculent charlatanry, gross mysticism, and strong common-sense, who called himself Philippus Aureolus Paracelsus Theophrastus Bombastus—the general impression is not wholly satisfactory, and to trace the historical connection of the several epochs presupposes more knowledge than Prof von Meyer imparts. It is hardly possible to do justice to the age of alchemy in 40 pages, or to the history of the latro-chemical period, which includes the work not only of Paracelsus and his school, but also that of Van Helmont, George Agricola, Palissy, and Glauber, in 30 pages But with the "Geschichte der Chemie" before him, Prof von Meyer may well have hesitated to plough with the patient heifer of Hermann Kopp

In his fourth chapter, where he deals with the period of the phlogiston theory, the author begins to expand somewhat, but occasionally, we venture to think, at the expense of strict historical accuracy Thus it is not strictly true to say that Kunkel laboured "for years" to discover the secret of the preparation of phosphorus (p. 141), or that Cavendish defended the phlogistic theory "with all his might" (p 118) That singularly austere and passionless person-that "cold clear Intelligence," as Wilson calls him-was utterly incapable of entering the lists as the champion of any theory He let his Irish friend Kirwan, to whom it was more congenial, do all the fighting It is hardly correct to describe the calm and philosophic Priestley as "eccentric and of a restless fiery nature." No man gave and got harder knocks in his time than did the kind-hearted, even-tempered old philosopher, he, too, did his fighting "all in the way of business," hitting straight and above belt, and with no malice in his blow, but to call him "eccentric," or "restless and fiery," reveals an entire misconception of his disposition and character The occasion of Lavoisier's admission into the French Academy is only partially stated, and it is not wholly true to say that amongst all his numerous friends and admirers only one chemist. Loysel, had the courage to protest against his execution (p 153)

A word in conclusion as to the manner in which Dr. McGovan has done the work of translation. His saim, be tells us, has been to reproduce clearly the sense of the German onginal, and in this he has, no doubt, succeeded admirably. But a purist might object that, in his efforts to preserve the sense, he has too carefully retained the tidom. To say that "the absorption of medicine in chemistry, the fusion of both together, was the watchword which emanated from Paracelsus" (or 3) is scarcely

a happy method of expression. Nor is this paragraph much better —

"Spirit of wine—the agua vita of the alchemists—continued to grow in importance during the intro-chemical age, as it had done in the alchemistic. This applied to it not merely from a theoretical point of view, as being a product of various fermentation processes to which much attention was paid, but also from a practical, since Paracelsus and his disciples used it largely in the preparation of essences and functures" (190 of essences and functures "(190 of essences and functures" (190 of essences and functures "(190 of essences and functures" (190 of essences and functures "(190 of essences and functures "(190 of essences and functures" (190 of essences and functures "(190 of essences and functures" (190 of essences and functures "(190 of essences and functures" (190 of essences and functures "(190 of essences and functures" (190 of essences and

On p. 10., Boyle's manor in Dorsetshire is erroneously called "Subfridge," and on p. 185 "Dalon" is in-correctly printed for "Davy." Such terms as "centre-point" and "fire-stuff" are not current English Dr McGowan's duty as a translator doubliess required him to say that "the nobility and poetry of his [Davy's] nature are shown both in the journals which he kept adming his extensive travels in France, Germany, and Italy, and in his beautiful relations to Faraday." (p. 187), but the veracious historian, familiar with the annals of the Royal Institution, would probably have expressed the Royal Institution, would probably have expressed.

PROGRESS IN ELEMENTARY BIOLOGY

Lesson: in Llementary Biology By T Jeffery Parker, B Sc, F R S, Professor of Biology in the University of Otago, New Zealand. (London Macmillan and Co, 1891.)

TOROF JEFFERY PARKER is to be congratulated on having produced an extremely well-written, well-considered, and original class-book. The teaching of so-called "elementary biology" has, in consequence of the coercion of examination schedules and the multiplication of little cram-books dealing with the selected and protected "types," become in this country a very poor thing. The practical work in the laboratory with frog, fern, rabbit, and worm, which was, when first introduced, a step in advance, has become, like so many other things which were good in their origin, a tyranny and an impediment to knowledge Students have resolutely shut their eyes to all facts but those presented by the schedule types, and teachers of a certain class have seen the easiest way to secure "examination results" in genoring the generalizations of biology, and in plying their pupils with the regulation details as to the few animals and plants scheduled for dissection Prof Parker's book should help to remedy this state of things His aim has been, he states, to supply the connected narrative which would be out of place in a practical hand-book. agree with him that the main object of teaching biology as part of a liberal education is to familiarize the student not so much with the facts as with the ideas of science. In this little book the student will find many of the most important conceptions of biological science set forth and illustrated, not by reference merely to the types which he dissects or examines with greatest ease in the elementary course in a laboratory, but by the use of a larger area of well-chosen examples, both of plants and animals. Original woodcuts, often of exceptional merit, are freely introduced in the text

Whilst the plan of Prof. Parker's book is excellent, I cannot help feeling some regret that he has not carried

it out on a somewhat larger scale, so as to make his volume represent for the blodgy of to-day what the classical "Comparative Physiology" of Dr Carpenter did for the blodgy and the properties of the thing the comparative Physiology" of Dr Carpenter did will be readed to—if it be a defect—is one which can very well be remedied beneafter, since the author will undoubtedly have an opportunity of expanding his book in every direction in a later edition in a later edition in a later edition.

Nearly half the book is devoted to the consideration of the phenomena of life as exhibited by unicellular organisms-the Protozoa and Protophyta There can hardly be any doubt that this is by no means an undue proportion, since it is unquestionable that in these simplest forms the fundamental problems of biology present themselves in the clearest light. We have well-illustrated chapters on Amœba, on Hæmatococcus, on Heteromita, on Euglena, on the Mycetozoa, and then a comparison of the foregoing organisms with certain constituent parts of the higher animals and plants, viz. cells. The minute structure and division of cells and nuclei are fully treated and well illustrated. Then follow separate chapters on yeast, on bacteria, on biogenesis and abiogenesis, and on the more complicated unicellular animals-the Ciliata. from among which are chosen Paramocium, Stylonichia, Oxytricha, Opalina, Vorticella, and Zoothamnium A chapter on species and their origin, and the principles of classification, comes next, the illustrative examples being chosen from among the Protozoa already described The Foraminifera, Radiolaria, and the Diatomaccæ are then brought under consideration. In every chapter the organism or group of organisms treated is made to serve as the concrete basis of a gradually expanding and connected narrative Thus, in passing to the consideration of such forms as Mucor, Vaucheria, and Caulerpa, the author savs -

"The five preceding lessons have shown us how complex a cell may become, either by internal differentiation of its protoplasm or by differentiation of its cell-wall. In this and the following lessons we shall see how a considerable degree of specialization may be attained by the elongation of cells into filaments?

A pause 13 now made, and a brief but thoroughly upto-date chapter 13 inserted on "the distinctive characters of animals and plants." Prof Parker thinks there 13 a great deal to be said in favour of Hackel's Ithrid organic kingdom—the Protista I do not agree with him in thinking that it is probable that the earliest organisms were "protists," and that from them animals and plants were evolved along divergent lines of descent

If we approach this question, not with the attempt to define plants and animals verbally, but with the object of indicating probable lines of descent, the groups once times considered as doubtful, and therefore "proting" take rank with great probability either in the animal or the vegetable series. The Mycetoron and the Volvocines fit quite naturally in the animal series, they would be isolated among the Protophyta, and, conversely, the Bacteriaces are inseparable from the Oscillatories and other filamentous green plant.

Prof Parker next proceeds to deal with plants of increasing complexity of structure and function—Penicillum, Agaricus, Ulva, Laminaria, and Nitella; ard, as a parallel to these in the animal series, we have two chap-

ters, with excellent woodcuts, on Hydra and on the Hydroid polyps, their colony-building and their alternation of generations The extremely important facts and theories of spermatogenesis and oogenesis and of fertilization are next set forth, briefly but clearly, and in sufficient detail for the general purposes of the book. In connection with the early development of the fertilized egg-cell of the Metazoon from its unicellular phase to the condition of the diblastula, the question is considered as to how we are to suppose that the passage took place historically from Protozoa to Metazoa or Enterozoa It is pointed out that there is a break here in the series of living animals known to us, whilst there is no correaponding break in the series of plants there we pass by insensible gradations from unicellular forms to linear aggregates of cells, and from these to superficial and to solid aggregates

The Mayosphara planula described by Haeckel in 1870 is cited as an animal tending to bridge over the wan in the animal series, but a footnote informs the reader that "unfortunately nobody has since seen this organism" Prof. Parker probably is awaie that this is also true of Haeckel's Protomy to aurantiaca, which he figures and describes in an earlier chapter. It certainly is to be regretted that neither of these interesting organisms has been observed again since they were de scribed by Haeckel However, Volvov globator is always with us, and Prof. Parker gives an excellent set of figures and a description of it, and proceeds to show how a twocell-layered sac-the ancestral gastrula or diblastulamight have been derived from such a colony. He also shows how a primitive diploblastic form might have developed from a multi-nucleate Protozoon, such as Opalina or Oxytricha.

In the laboratory it is convenient to take the Earthworm as an example of that central type of structure which is found under various modifications in all the Colomate animals Prof Parker, rightly separating himself from the ties of laboratory work, prefers the marine worm Polygordius for his illustration of this grade of structure, choosing it partly on account of its greater simplicity, partly on account of its extremely interesting and well-studied developmental history As the author contends, a student who reads the two chapters here devoted to the anatomy, physiology, and development of Polygordius, will have an immense advantage either in his subsequent study of the Earthworm, or in reverting to his notes of a previous dissection of that worthy beast The principle of the comparative method will be revealed to him, and he will learn to distinguish things essential from things non-essential

Next, with a rush, having scaled the long ladder leading to Polygordius, Prof Parker takes his reader in one chapter of seventeen pages through the anatomy and morphology of the starfish, the crayfish, the mussel, and the dogfish This seems and is rather rapid, but the rapidity is intentional and justifiable. By the and of this book the student is intended only to gain a general view of the structure of those animals as comparable to that of Polygordius. For further details he must go on to the special study of animal morphology, physiology, and embryology, or having studied these subjects more test, he man, by and of Prof. Farker's clever sche-

matic woodcuts, gain a wind impression of the unity of organization and the divergence in minor points of structure of the higher animals when compared one with another. Perhaps, however, in that enlarged edition of this blook which will are no distant date appear, For Parker will treat the higher animals less unceremonously, this he might do, and yet retain that conciseness and regard for the essential which form an admirable characteristic of his method.

Mosses and Ferns are treated as the parallel among plants of Polygordius in the animal series, and in a single chapter Equisation, Salvina, Selaginella, Opmosperms, and Angiosperms are surveyed (and excellently illustrated by finished woodcuts) in such a way as to give the student an accurate and highly effective survey of the restart features of orgestable morphology and physiology.

Such is the outline of these "Lessons". Their ment, however, consists not merely in the general plan, but in the fact that the author is an experienced teacher and an accomplished investigator, who has developed to a high degree the art of loud statement—one who is thoroughly familiar with the latest researches in the wide field of which he treats, and is able, whilst stering before his reader the most important generalizations of his science, to avoid redundancy, and to give a fresh and original handling to the oft-told story of the structure and functions of lying things.

E RAY LANKESTER.

CEREBRAL LOCALIZATION

The Crooman Lectures on Cerebral Localization By David Ferner, M.D., LL.D., F.R.S., &c With Illustrations (London. Smith, Flder, and Co., 1890)

In these valuable lectures, Dr. Ferrier reviews the subject of cerebral localization, so far as the representation of movement and of special sense is concerned. After referring categorically, in the first of the sense, to the historical experiments on the subject, arranged in order of chronological sequence, he points out the fundamental principles embodied in the term cerebral localization. Leaving the discussion of motor representation, he devotes the remaining five lectures to the consideration of the cortical representation of the special senses, beginning with that of sub-

The representation of sight is, according to all observers, mainly restricted to a definite area of the cortex The differentiation of that area and its topographical subdivision are points of the highest interest, and naturally do not escape discussion We are rather surprised, however, to find that Dr Ferrier is not prepared to admit that Munk and Schafer's experiments, besides those of other observers, establish visual representation to be situated in the occipital lobe, but is inclined to believe that the angular gyrus is the centre for clear vision mainly for the eye of the opposite side. Upon this we would only remark that it does not appear to us that the mass of evidence relating to crossed hemianopsia, whether of experimental or clinical nature, can be put aside as easily as Dr Ferrier would seem to consider possible, but those interested in the subject will find many of the facts bearing on this question referred to in his treatment of the points at issue.

So, too, with the representation of audition, while all (awar Schafer's and Sanger Brown's) observations support Dr Ferner's views of the seat of representation of hearing, it would undoubtedly have been better that the rebutting evidence brought against the exceptional facts referred to should have consisted of a number of experiments, and not of a single one, even although that seems to have been a very conclusive observation

After disposing of the centre of audition, the tactile centre receives attention, and is preceded by a discussion of the paths along which afferent impressions travel in the spinal cord to the higher centres. Of course, this subject has been very actively investigated by various observers for many years, but it has always appeared to us that sufficient attention has never been given to the simple consideration whether or not the lower centres are engaged in the transmission of such impulses. In the limited space at Dr. Ferrier's disposal he has evidently not been able to give this matter full discussion, and is therefore led to assume that Brown Scouard's dictum respecting the passage of afferent (tactile, not painful) impulses up the opposite side of the cord holds good This question is now being reinvestigated, and the preliminary observations published by Mott and others throw very grave doubt on the validity of this assumption, which has so long been accepted as final

As regards the representation of common tactile sensation in the cortex cerebri, Dr Ferrier discovered that it was probably represented in the hippocampal region, and he reviews the results of his experiments, as well to those of Schafer and Horsley, which tended to show that the gyrnis fornicatus, as well as the hippocampus, were the seat of tactile perception, and he concludes that possibly the whole limbic lobe is concerned with this representation

As regards, however, the representation of sensation in the exitable or motor part of the cortex, he will "have none of it." Here, again, we are afraid that the considerations of time and space, which always handicap subjects treated in lecture form, account for the fact that the critical examination of this question is not so complete as perhaps it might have been made

On the whole, these lectures well maintain the author's high reputation as a keen observer, and an indefatigable student, gifted with singular clearness and distinctioness of expression, and they will well repay perusal by all who wish to follow the progress of knowledge of corebral localization and its most important bearing.

OUR BOOK SHELF

Education and Heredity By J. M. Guyau (London. Walter Scott, 1891)

This small and excellently-translated work is a posthumous publication, written by a Frenchman who died four years ago at the early age of thuty-three. He was a fluent and prolife writer, the author of no less than fourteen other publications, and is described in the introduction as a philosopher and poet. It would seem from this book that the latter temperament was his prevalent the characteristic. Its prevalent hierary style and the originality both of metaphor and of handling will commend itself, and so will the account of recent hypotoic in-

vestigations, and the use made of them in the argument. Interesting and appropriate quotations are inserted from numerous authors of fame and notoriety, as from Plato, Decarates, Lebenitz, and Spencer, down to Toiston. But when, after reading right through the book, one asks when the control of the contro

"A forth clearly the state of t

inheritance is very slightly efficient

The following paragraph will serve as an example of what is least good in the author's style and method.— "Why then should not the representation of man, by hereditary tendency, excite in man himself a peculiar pleasure, and an inclination no longer of tlight, but to approach, speak, be helped, to put others in his place?
When a child falls under the wheels of a carriage, we precipitate ourselves to its rescue by an almost instinctive inovement, just as we should start aside from a precipice The image of others is thus substituted for the image of ourselves. In the scales of the inner balance, I, thou, are constantly interchanged. This delicate mechanism is partly produced by heredity Man is thus doinesticated, made gentler, and more civilized, now he is partially savage, partially civilized or civilizable. The result of education through the ages is thus fixed in heredity itself, and this is one of the proofs of the power possessed by education, if not always for the present, at least for the future "

Life is short, there is much to learn, and economy of time is important. It is questionable whether it is worth the while of a person who has some acquaintance with the subject of this book to spend half a working day in reading it, for he might not find it as nourishing as he would wish. Still it is not tulkley that those to whom the subject is unfamiliar would gain instruction from the book and would consider it throughout to be interesting.

The Soul of Man an Investigation of the Facts of Physiological and Experimental Psychology By Dr Paul Carus (London, Edward Arnold)

It is in vain that a puzzled reader seeks to discover, the unof this book. It is entitled "The Soul of Man," but no explanation is given as to what is meant by the title, and at the end of forty-sar rambling and discursive chapters on things in general, the reader finds himself no wiser. It is called "an Investigation of the Facts of Physiological and Experimental Fsychology," but there as anatomy, of embryology, of neorology, &c., are set forth, such in the form in which they can be found in elementary text-books on the subjects, but the facts this presented are not investigated, they are presented in now hight, no new conclusions are drawn from them, and the object of their presentation does not appear. Here the prefer he chains originally, he held for which instance, that consciousness (which he calls a concentrated or intensified feeling—an additional element that some-

times is, and sometimes is not, attached to mental operations) is "produced" in the corpus stratum. It does not appear, however, that this hypothesis leads anything, or has any appreciable bearing on the "problem anything, or has any appreciable bearing on the "problem thinks, too, that man has two souls, a central soul and a peripheral soul; and it is thus that he explanas the familiar fact that certain purposive actions are unattended with consciousness, but we cannot say that this explanasciable in the supplication of the supplication of

The Recent Earthquakes in Italy

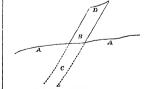

WITH reference to the letter which appears in your issue of big 33 (p. 27), on the earthquake, having occurred it Ventuus on June 7, and on the same day in Southern Australia, I would be supported by the same of the same of the same of Australia, I would warmly of a great circle which I call the "south-west coast of Australia great circle which I call the "south-west coast of Australia great circle which I call the "south-west coast of Australia great circle with a land to the about 370 of Catanaro, leaving Venurus about 65 miles to the north line great circle so one of maximum compression on the earth's surface—that is, it less for the most part on the occus surface—that is, it less for the most part on the occus surface—that is, it less for the most part on the occus surface—that is, it less for the most part on the occus surface—that is, it less for the most part on the occus surface—that is, it less for the most part on the occus surface—that is, it less for the most part on the occus surface.

It is also worth noting that, while you cate in the same is two shocks as having occurred in the Ardian Islands on June 24 (of these, Stromboli lies about 40 miles woulh of the direction of this great circle), there was recorded on that day, in the newspacers, an earthquade shock as having taken place on the 270 (midnight) at Christians, South Carolina, which lies about in question at this point, and therefore approximatively in the wintil,

Royal College of Science for Ireland, Stephen's Green, Dublin, July 24.

The Great Comet of 1882.

It your tout of May 38 (p. 81) is a communication about the contest of 1882 as seen in the act of passing close to the sun. As attention has thus been called to that count. I desure to report a remarkable penalinarity of the tail vs. whereved by myself. October 3, 1882, about daybreak. It was my first view of this glorous contest. Other persons on the east sales of the installs had seen contest. Other persons on the east sales of the installs had seen contest. Other persons on the east sales of the installs had seen contest of the penalinary of the tail, which was cut off tharply at an oblique angle, on an incurred then. The following representation is correct

from one in my note-book made at the time. AA represents the eastern ridge of the Kahakuloa canyon on the north end of Mans, where I was sleeping. B is the brilliant end of the vast tail like a scimutar blade, fully as bright as the moon. C is

copied from my note-book. It was evidently meant to indicate the continuation of the init towards the nucleus, as seen on minal edge of the tail, as sharp as the outer limb of the moon, and of fullest strength of lustre. Altogether it formed a rather papilling apparation Clouds soon obscured it. No farther yiew was obtained for two or three days, when the end of the tail had

was obtained for two or three days, when the end of the tau nau assumed the usual musty, indefinite outline The conclusion forced upon my mind was that the comer, having parted with its fall in its rapid turn at the per wall of water that heads a freshet in a stream. Another re-semblance suggested was that of the solid looking outline of an

up-rolling cumulus cloud

I will add hereto a statement made to me at the time by the Rev. Iliram Bingham, a distinguished pioneer missionary to the Gilbert Islands He saw the comet about a week earlier than myself, from Kancohe, on the east side of Oahu Both he and myeri, from kaneone, on the case sate of value 1 hours of and his wife observed ceaves of frishmats (colour) summing outcomed along the hrilliant tail. Mr. Bingham is a highly cultivated person, and having commanded the missionary ship for part of two years, is accustomed to lunar and stellar observation. I was led at the time to believe that there was no optical illusion in what he saw SPRENO E BISHOP

Copenoda as an Article of Food

PROF HERDMAN's practical demonstration at the North Cape confirms a theory I have long held, that the Copepoda, which abound in every ocean, sea, and lake, might and advantageously made available for human food

It is well known that the species Calanus finnarchicus, so abundant in our northern seas, forms the chief food of the Greenland whale our northern seas, forms the chief food of the Greenland whale to four wom immediate coasts about an in his and other equally four wom immediate to said should be sufficient to the control of Man, each pull of the tow net contained thousands of Man, each pull of the tow net contained thousands of mother and larger species of Coppoint, Ammodieve aparterisms, and Dr. John Murray has found that a still larger-species, Euchard and Dr. John Murray has found that a still larger-species, Euchard A number of finely methed trunks, used off the west coast of Ireland, would, I am convinced, furnats excellent food for starring multitudes in time of freed.

A propos of the distribution of Copepoda, my attention was called a few days ngo by the Mayor of Bootle to the filter-beds of the town salt water baths, which he said were swarming with Entomostraca The water is supplied direct from the river, of Inte (bown sate was the property of Coppeda an encommon quantities, the balk of them heing European alterants, a species only once before taken in Britan, and then in near proximity to Bootle Probably other filter beds are equally prolife, and may prove valuable hanting grounds, the Coppeda undoubtedly acting as exavengers in keeping the water pure from patrickets.

Liverpool, July 24.

Meteorological Phenomenon

I HAVE received in a letter from a friend residing in Bornston, Shropshire, the following account of a remarkably interesting meteorological phenomenon, which is well worth putting on

record — a cursous sight from this house yesterday [July 26] It was a dead caim, but in a field just below the garden, with only one hedge between us and it, the hay was whirled up high into the sky, a column connecting above and below, and in the course of the evening we found great patches of hay raining the course of the evening we found great patches. down all over the surrounding meadows and our garden. It kept falling quite four hours after the affair There was not a breath of air stirring as far as we could see, except in that one

Refraction through a Prism.

In such elementary text-books on geometrical optics as I have consulted it has always seemed to me that the writers have found a difficulty in presenting a precise direct proof of the theorem that when a ray is turned out of its course by direct

passage through a prism, its deviation is least when its path is symmetrical with regard to the prism.

May 1 ask you to consuler the simple proof which I inclose,

May I ask you to consider the simple proof which I inclose, and may I leave it to your judgment whether it is worth while that it should be presented to the notice of teachers in the pages of NATURE? My knowledge of text-books I cannot suppose to be exhaustive, and the arrangement of the proof which I inclose

TOHN H KIRKBY. Radley College, Abangdon, June 11

of course may not be any novelty.

Menmum Deviation.

The problem is to find two rays which, passing directly through a prism near together, have their directions changed by the prism to the same amount—for in the limit, these, when brought into coincidence by change of position of the prism, will mark the course of that ray which suffers minimum deviation (experiment may be appealed to, to show that it is minimum

and not maximum) Let ABCD be the course of a ray of hight through the prism whose vertex is V. At B make the VBC' = 4 VCB, then if the ray BC' is continued out of the VBC = 4 VCB, then if the ray BC is continued out of the prism on hoth sides, it is evident that its completion DC'BA' meets and leaves the faces of the prism at exactly the same angles as the original ray ABCD, only in the opposite direction. Thus the two rays A BCD, ABC D' suffer equal deviation, and because the Δ×VBC, VCB are similar,

and when the rays are so close as to practically render C, C' co-incident, we have $VB^2 = VC^3$, or VB = VC when the devia-tion is a minimum, $i \in t$ the deviation is a minimum when the course of the ray makes equal angles with the sides of the

[Oxford men will remember that more than twenty years ago Prof Clifton gave a somewhat similar proof as follows —
Since the paths ABC1) and D'C'BN are similar, if one is a
path of minimum deviation the other must have the same property also Hence, since light can always travel in the reverse direction along a path, the paths

ABCD and NBC'D

are both paths of minimum deviation

But the existence of two such minima is contrary to experi-ment. Hence the paths must be identical, which can only be the case of the angle VBC = VBC' = VCB - ED.]

Further Notes on the Anatomy of the Heloderma.

SINCE I published in NATURE (vol. alin. p. 514), "The Poison Apparatus of the Heloderma," there has appeared from the pen of Mr Boulenger another notable contribution to the pen of Mr. Boulenger another notable confribution to the anatomy of that genus of repities, entitled "Notice on the Osteology of Melode ms. horrsdam and M. anpfertum, with the Vertebree of the Lacritin, "If 2.5..., January 2.0.. 1891. That paper is especially useful, insamuch as it critically compares the vertebral columns of the two speces of Lazards under consistence of the Compare of the Compares the C he assigned to them in 1884, in feel to pass some observations. In concluding this notice I am led to pass some observations. In concluding this notice I am led to pass some observations are considered to the passer upon my memor on the anatomy of II superium when apparent in the Free of the Zool Soo of London in 1890. His criticism of my description of the alias of II superium is well as the contract of the criticism in the criticism of my description of the alias of II superium is well and the my description of the my direct of the context opening of the criticism is not of the criticism in the context opening of the criticism is not of the criticism in the criticism of the criticism is not only as the criticism is not only as the criticism is not of the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the criticism is not only as the criticism in the criticism in the presentation in the presentation plane, when the skell is perfect. THE DISCOVERY OF THE STANDARDS OF 1758.

THE discovery by the Clerk of the Journals of the House of Commons, referred to in NATURE last week (p. 280), of the original standards of length, which were in 1738 deposated in the custody of the Clerk of the House, has attracted some attention to the history of these Parlamentary standards. As some misapprehension as to the effect of such discovery appears to have arisen, and as it is to eminent men of science that we mainly indebted for our standards of length, the readers.

The standards of length above referred to were made under the directions of a Committee of the House of Commons, of which Lord Carysfort was Chairma, appointed on May 26, 1758, "to inquire into the original standards of weights and measures in this kingdom." The Committee reported that in 1742 several members of the Royal Society were at great pains in taking an exact measure of the ancent Exchequet standards of length of

Henry VII. and Queen Elizabeth), then condemned by the Committee as being coarsely made and "bad standards" that such measure was made by "very curious instruments prepared by the late ingenious Mr. Graham", and that the Royal Society had lent to the Committee a brass rod made pursuant to these experiments, which rod had been com-pared by Mr Harris, of the Royal Mint, with the Exchequer standards Mr Harris advised the Committee that the Royal Society's standard was made so accurately, and by persons so skilful and exact, that he did not think it easy to obtain a better standard; and accordingly the Committee then had two rods made by Mr Bird, an optician, according to Mr Harris's proposal, which "rods" were laid before the House The rod marked "Standard Yard, 1758," was to be taken as the proper standard, it was stated by the Committee to be made of brass, to be about 38 or 39 inches in length and about one inch thick, near to each end of the rod a fine point and line being drawn on a gold stud, the distance between the points on the gold study the "true standard length of a yard, 36 inches The second rod was made in the same manner as the first rod, excepting that it had " two upright cheeks" instead of points or lines, so that any other yard rod might be measured by being placed between the cheeks Both these rods (together with three standard troy pounds

marked "T," with a crown and "G.2," and a set of troy

1758
standards from 2 pounds to 32 pounds, made and adjusted
by Mr Harris "with very curious and exact scales of his
at the Mint") were stated by the Committee to be then
deposited with the Clerk of the House of Commons

in 1838 the attention of the Government was directed to the necessity of determining a new standard weight and measure to replace the above standards of 1758, which were stated by the Chancellor of the Exchequer-in a letter to Mr. G. Airy, the Astronomer-Royal—to have been "destroyed by the burning of the Houses of Parliament," and a Commission was appointed to restore the standards. The Commission included F Baily, J E D Bethune, Davies Gibert, J S Lefevre, J W Lubbock, Geo Peacock, R Sheepshanks, J Herschel, and G B Airy Their report of 1841 gives a precise description of the condition of the standards at the Journal Office immediately after the fire. The Committee reported that the legal standard of one yard was " so far injured that it was impossible to ascertain from it with the most moderate accuracy the statutable length of one yard", and also that the "legal standard of one troy pound was missing" New Parliamentary standards of length and weight were accordingly made under the directions of the Committee, and were legalized by an Act of Parliament passed in 1855. These new Imperial standards are now deposited with the Board of Trade, but legal "Parliamentary copies" of them are stated to have been immured, in 1853, in the House of Commons, and further copies were then deposited at the Royal Mint, the Royal Observatory, and with the Royal Society These latter Parliamentary with the Royal Society These latter Parliamentary copies are legally required to be compared with each other once in every ten years, but those deposited at the House of Commons are excepted from any such comparison. It would appear, however, that the House of Commons standards are sometimes examined, as is shown by some printed correspondence on this subject which was laid before the House of Lords in 1872, in which year the standards were examined, and after their examination were again immured in a wall near the lower waiting hall of the House of Commons; a certificate of

the deposit of the standards being given as follows—
"It is hereby certified that this day, in the presence of
the undersigned, the oaken box containing the Parlamentary Copy No. 4 of the Imperial Standard Vard,
and the Imperial Copy No 4 of the Imperial Standard
Pound," . . has been "deposited within the wall on the right-hand side of the second landing of the public the right-hand side of the second landing of the public staticase leading from the lower waiting hall up to the Commons Committee Rooms, a brass plate having been fixed upon the wall bearing the following inscription in Elizabethan or church text—Within this wall are de-Elizabethan or church text —Within this wan are de-posted standards of the British Yard Messure and the British Pound Weight, 1853. The certificate is signed by G B Airy (Astronomer-Royal), John George Shaw Lefevre (Clerk of the Parliaments), W H Miller, C P. Fortescue (President of the Board of Tradel, H W. Chisholm, and H. J Chaney; and is dated March 7,

It hardly appears, therefore, that the old standards of 1758, which appear to have remained unnoticed for the past fifty years, are now of any importance for the purposes of measurement.

MAXWELL'S ELECTRO-MAGNETIC THEORIES

A N account of Maxwell's electric theories from the pen of Prof Poincaré could not but be full of interest. The volume before us is the first of two on the views and conclusions set forth in the " Electricity and Magnetism" regarding electro static and electro-magnetic action, and their verification by Hertz and others, and we must of course wait for the completion of the work before we can form any adequate idea of its scope and character. and fully understand the results of the critical analysis which it contains But in spite of the fact that the treatise is in the somewhat disadvantageous form of an edited course of lectures, it is a contribution of great value to the literature of the subject. Whether or not it is possible always to agree with the physical views expressed regarding matters which are not yet outside the region of speculation, it is impossible not to admire its style and methods. Here are to be found exemplified that order and harmony which render the work of the best French mathematical writers so exquisitely clear, and that artistic charm which is so seldom seen in the writings of scientific men of other nationalities It has been remarked by competent critics that Maxwell's work, though essentially that of an artist and man of genius, is obscured here and there by a certain vagueness and want of logical coherence and completeness, which has tried the patience and strength of many a devoted disciple This was of course to a great extent inevitable. He sought out new fields of speculation for himself, and his greatest and most successful generalizations were, one cannot help feeling, the results rather of unerring intuition than of any completely systematic process of reasoning. Those who follow in his foot-teps therefore are glad of the help of any friendly guide who is able by his experience and strength to point out the dangers and diminish the diffi-culties which attend their progress

In his introduction Prof Poincaré gives a critical

estimate of Maxwell's theories which strikes one at first

sight as somewhat inappreciative Thus he says —
"La première fois qu'un lecteur français ouvre le livre de Maxwell, un sentiment de malaise, et souvent même de défiance se mêle d'abord à son admiration. Ce n'est qu'après un commerce prolongé et au prix de beaucoup d'efforts, que ce sentiment se dissipe. Quelques esprits éminents le conservent même toujours. ouvrant Maxwell un Français s'attend à y trouver un ensemble théorique aussi logique et aussi précis que l'optique physique fondée sur l'hypothèse de l'éther, il se prépare ainsi une déception que je voudrais éviter au lecteur en l'avertissant tout de suite de ce qu'il doit chercher dans Maxwell et de ce qu'il n'y saurait trouver.

1 "Électronté et Optique " I. Les Théories de Maxwell et la Théé Électromagnétique de la Lumière. Par H. Poincaré, Membre de l'Insui (Paris Georges Carré, 1890)

%NO. 1135, VOL. 44]

"Maxwell ne donne pas une explication mécanique de l'électricité et du magnétisme : il se borne à démontrer

que cette explication est possible.

"Il montre également que les phénomènes optiques ne sont qu'un cas particulier des phénomènes électromag-nétiques De toute théorie de l'électricité on pourra donc déduire immédiatement une théorie de la lumière.

"La réciproque n'est malheureusement pas vraie, d'une explication complète de la lumière, il n'est pas toujours aisé de tirer une explication complète des phéno-

mènes électriques."

The author, however, shows throughout his exposition that he is not only impressed with the extraordinary importance of Maxwell's work, but also thoroughly appreciates and admires, if occasionally under protest and with longing after the more ancient classic models, its somewhat wild and native beauty

An important part of the introduction is an exposition of the theoretical basis of what Prof Poincaré rightly regards as the fundamental idea of Maxwell's treatment of electro magnetism- that is, the application of the general processes of dynamics to any system of current-carrying conductors No doubt almost all the work which had been done previously had been more or lessof this nature, but we refer here to the attempt which Maxwell made with very considerable success to correlate electro-magnetic phenomena by means of Lagrange's general dynamical equations

In the Lagrangian method the physical state of a system is defined by means of certain parameters q_1, q_2 system is defined by means of certain parameters g_{11} , g_{22} , g_{31} , g_{32} in number, and a dynamical explanation is obtained, or proved to be possible, when the values of these parameters are found in terms of, or proved to be related to the positions and motions of a system of con-

nected particles, either of ordinary matter, or of some

If $m_1, m_2, \dots m_p$ be the masses of these particles, x_i, y_i, z_i , the Cartesian co-ordinates of the particle of mass m_i , and if the system have potential energy V, a function of the 3p co-ordinates of type x_i , y_i , z_i , there are 3p equations of motion of the form

$$\begin{array}{c}
m_i x_i + dV/dx_i = 0 \\
& & & & & & \\
& & & & & & \\
\end{array}$$
(1)

The kinetic energy T is

$$\frac{1}{2}\Sigma m \left(x^2 + y^2 + z^2\right),$$

and the principle of conservation of energy gives T + V = constant

Now we know V, and can express the co-ordinates of each particle or molecule in terms of the n parameters gu, g,, q,... The celebrated Lagrangian equations in terms of the parameters can then be obtained by direct transformation of (1), and are of the type

$$\frac{d}{dt}\frac{\partial \mathbf{T}}{\partial q_k} - \frac{\partial \mathbf{r}}{\partial q_k} + \frac{\partial \mathbf{V}}{\partial q_k} = \mathbf{0}$$

Here T and V are homogeneous quadratic functions, the first of the quantities of type q, with coefficients which are functions of the parameters themselves, the latter of the parameters only

If we have reason to believe that the system we are

dealing with is a dynamical system, for which the values of T and V (or, more properly, those parts of the total kinetic and potential energies which are concerned in the special phenomenon treated), can be obtained by observation of parameters of type q, we can use these equations in our discussions of results, whether or not we can actually express the parameters in terms of co-ordinates of particles of the system The justification of this process is the agreement of the results with experiment.

If now we imagine a system of particles (whether of

actual or hypothetical matter) say ø in number, which has the required values of T and V, and which further gives the same relations of the parameters ø, we have obtained a dynamical explanation of the phenomenon Prof Poincard remarks with respect to this process that no dynamical solution of the problem obtained in this way can be unique, and that in fact it must be possible to obtain in this way an infinite number of different solutions, or to quote his own words:—
"If any phenomenon admiss of a complete mechanical "if any phenomenon admiss of a complete mechanical"

"If any phenomenon admits of a complete mechanical explanation it will admit of an infinite number of others which equally well account for all the results of expen-

mention and the second of the second of the second of physical inquiry. Theorem remonsterin with one another are elaborated by different persons, and explain the known facts owell that there is hardly anything left to decide which is right. For example, according to Fresnel the direction of vibration in a ray of plane polarized light is perpendicular to the plane of polarization, according to Neumann and Mucc ullagh it is in the plane of polarization. It can hardly be said that any perfectly absolute experimentum crusts has yet been found to decide between these two theories, although the other second of the vew of Fresnel.

It is, however, to be remembered that while we can and different mechanical theories to explain the facts, the theories are not necessarily distinct, the mechanism of the facts which must be performed by the actual mechanism whatever that may be always is, as the above cited case well illustrates, a unity connecting the different explanations and a consequent element of similarity among them, and each sutvitactory modes of deciding in what respects it is redundant or madeounted.

The difficulty then as to real mechanical explanations of phenomena does not present us from making progress in our knowledge of matter. The Lagrangian method, and this is its remarkable intent, enables us to use the parameters instead of the co ordinates of actual particles, and thereby to predict the extence of further properties and thereby to predict the ordinates of actual particles, and thereby to predict the further ordinates of actual particles, and thereby considerable of the constraint of the properties observed. In this way may be lightened the task, happing to the constraint of the properties of the particle of the properties of the properties of the particles of the properties of the particles of the properties of the particles of the particles of the properties of the properties of the properties of the properties of the particles of the properties of the particles of the particl

There seems, however, no doubt that Prof. Pomerar's correct in his view that the central idea of Maxwell's treatise is to prove the existence of a mechanical evplanation of electrical phenomena, not indeed actually inding it, but by showing that the Lagrangian method, which presupposes such an explanation, is applicable, and leads to consistent results

Coming now to the detailed exposition of Maxwell's theories, the first thing that calls for notice is the theory of electric displacement. This has always been a subject of considerable difficulty. What is electricity is it the placement of the considerable difficulty what is electricity is it the placement and representation of the considerable displacement and electric force remain simply analysis to the strain and stress in an elastic solid, and it can hardly be said that anyone has yet brought them out of the other displacement and electric force remain simply analysis to the strain and stress in Mo doubt the mechanical hardly be said that anyone has yet brought them out of the other displacement and electric force remain simply analysis of the other displacement and the strain of the other displacement and the strain of the other displacement and the other displacement and the strain of the other displacement and the strain of the stra

its on this account that Maxwell has abstained from giving such illustrations in his ireatise. On the other hand, some notion corresponding to that of electric displacement is necessary for any theory of electrical action regarded as propagated through a medium surrounding the electrified bodies, whose charges become thus the surface manifestation of the state of constraint set up in the dielectric by the electrification.

Prof Pomcaré distinguishes between two fluids—one which he calls electrizity, and the other the fluids statu-teur. Both fluids are incompressible, the latter fills all delectric space, the former is capable of being produced at or placed at any given place or on any given surface at or placed at any given place or on any given surface introduced, as, for example, when a change is pliced on the surface of a conductor, an equal quantity of the fluids fundateur is forced out across the boanding surface. When all the conductors of a system are in the neutral state, the fluids fundateurs is normal equilibrium, when, on the other hand, the conductors are electrified, the outpulbrium causes to be normal and the state becomes

There is some advantage in thus distinguishing between the fluid constituting the electrification and that filling the surrounding space, as it avoids some difficulties of explanation and treatment which arise when only one

On this result Frof Youncar' remarks that, although it agrees very well with the observed attractions and repulsions between electrified bodies, yet if these attractions and repulsions. The to be considered as due to the evistence of for that medium must be very different from those for fordurary substances. In electromotive force at a point correspond to the strain and electromotive force at a point correspond to the strain and stress in an elastic solid, but, for corresponds one different form of displacement and electromotive force at a point correspond to the strain and stress in an elastic solid, but, for corresponds one different form of displacement in the properties of the strain and stress in an elastic solid, but, for corresponds one different form of displacement or strain than any that have yet been imagined.

A difficulty here arises to which Poincaré attaches considerable importance. The potential energy in the medium is, if f_i , g_i , h be the component electric displacements, given by the equation

$$W = \int_{V}^{2\pi} (f^{2} + g^{2} + h^{2}) dv,$$

where dv is an element of volume and the integral is hypothesis as to the localization of the energy of the field, the amount contained in an element dv at which the displacements are f, g, h, is

$$K^{2\pi}(f^2 + g^2 + h^2)d\tau$$

or KF340/8w Consequently, if Fbe increased to F + dF, there will be an increase in the potential energy of amount 2KFdFdet/8m. If now the stresses act in the medium as ordinary stresses, they must produce corresponding strains in each element of volume. Hence if the element dv be a rectangular parallelepped of edges δ_1 , δ_2 , δ_2 when the field is free from electric stress, these dimensions will become, when an electromotive force F is produced at the element, respectively δ_1 ($1 + \epsilon_1$), δ_2 ($1 + \epsilon_2$), δ_3 ($1 + \epsilon_3$) fielder, if when F

is increased to F + dF, ϵ_1 , ϵ_2 , ϵ_3 become ϵ_1 + $d\epsilon_1$, ϵ_2 + $d\epsilon_3$, ϵ_3 + $d\epsilon_4$, the work done by the stresses will, neglecting small quantities of the second order, be

$$KF^{2}_{-8}dv(de_{1}-de_{2}-de_{3});$$

and if the increase of potential energy in the element take place in consequence of the work done against the stresses we get the equation

$$\frac{F^2}{8\pi}dv(de_1-de_2-de_3)=\frac{2FdF}{8\pi}dv,$$

-

298

$$de_1 - de_2 - de_3 = \frac{2dF}{F}$$
,

which gives by integration

$$e_1-e_2-e_3=2 \log F + \text{const.}$$

This result is inadmissible, since when F is zero, we must have $e_1 = e_2 = e_3 = e_3$ while if this equation holds either e_2 or e_3 is infinite

A solution of the difficulty is simply that the energy is not really potential but kinetic. It is certainly not easy to see why the electro-magnetic energy should be regarded as kinetic and the electro-static as potential, and it seems more natural to conclude, as all progress in knowledge of matter seems to indicate, that the properties of the medium are wholly due to motion

After a short sketch of purely magnetic theory, Ponnard proceeds to what must be regarded as the most important part of his account of Marwell's work—the theory of electro-magnetism. His investigation of the theory of electro-magnetism. His investigation of the from that usually given. Maxwell takes as his starting point here the equivalence of a current-carrying circuit of small dimensions and a magnet. Ponicaré bases his method directly on the following there results of experimental dimensions and a magnet conduction of experimental control of the properties of

With the assumption that the components of the force acting on a magnetic pole are obtained by partial differentiation of a function which depends only on the relative positions of the pole and the circuit, the usual theorems are obtained in the following elegant manner First of all it is shown that the potential of a closed plane circuit at any point in its plane is zero. This is first proved for a circuit symmetrical about a line on its own plane and a point on the axis of symmetry. Then by using the first fundamental proposition to introduce across the circuit straight conductors each carrying two equal and opposite currents equal to the current in the circuit, a circuit of any form is divided into narrow portions each bounded at the ends by elements of the circuit, and at its sides by radial lines passing through the point in question By using then the second proposition to replace each end-element of the circuit by a circular arc passing through the centre of the element and described from the given point as centre, each strip is turned into a complete circuit, symmetrical about a line through the given point. Since, then, the theorem is true for every such circuit, it is true for the whole given circuit which they build up. Next it is easily shown that when a circuit is situated on the surface of a cone but does not surround the axis—that is, is such that a generating line meets the circuit in an even number of points—the potential of the circuit at the vertex of the cone is zero. For, by means of conductors introduced along generating lines, and carrying equal and

opposite currents as before, it is possible with the aid of the second result stated above to replace the circuit by a number of narrow plane circuits each carrying the given current, and symmetrical about a generating line of the cone. Hence each element produces zero potential at the vertex, and therefore so also does the given circuit.

[JULY 20, 1801

vertex, and therefore so also does the given circuit.

One, and hassing through the axis, produce equal and opposite potentials at the vertex, if the currents are equal and flow in opposite directions round the cone. For by means of hypothetical conductors introduced as before along the generating lines, and the second fundable and the sense of the sense

Considering now any closed circuit, we can draw a cone from any chosen point as vertex, so that the generators pass through the circuit. Then this cone can be divided into an infinite number of infinitely small superposable cones of equal solid angle, each having a current flowing round it in the same direction as that round the given circuit, and the total potential at the common vertex is the sum of the equal potential is produced by three small circuits—that is, the potential is the circuit.

The equations connecting the components u_i, v_j, w_j of currents with the components of magnetic force and magnetic induction, the relations connecting the magnetic force and magnetic miduction, those connecting the magnetic force with the vector potential (which Foincaré calls the moment identermagnetique), and the value of the components of the latter quantity for a linear circuit with their application to the proof of Neumann's expression for the "electrodynamic potential" (the mutual intrinsic corresponding expressions for the "electrodynamic potentials" (electrokinetic energies) of the circuits themselves, are dealt with in the next two chapters

In chapter we we come to the most important part of the book, the theory of induction, and the treatment of this part of the subject is instructive. It is a result of the subject is instructive. It is a result of experiment that if the currents γ_1 , γ_2 in two fixed circumstructive. It is a result of experiment that if the currents γ_1 , γ_2 in two fixed circumstructives forces of $Ab\gamma_0 dt + Bb\gamma_0 dt$, $Bb\gamma_0 dt$, $Ab\gamma_0 dt$,

$$T = \frac{1}{2}(L_1\gamma_1^2 + 2M\gamma_1\gamma_2 + L_1\gamma_2^2),$$

 $\partial T = \frac{1}{2}(\gamma_1^2 dL_1 + 2\gamma_1\gamma_2 dM + \gamma_2^2 dL_2).$

so that the former work is

Thus the work dW done in virtue of the changes of the currents is the difference between this and the excess of

the energy given out by the batteries over that spent in heat. Thus

 $dW = E_1 v_1 dt + E_2 v_1 dt - R_2 v_2 dt - R_3 v_3 dt - \partial T;$

and this is the work done in virtue of changes of the and this is the WORK done in virtue of changes of the currents. This quantity must be a perfect differential, since its integral vanishes for a closed cycle of changes. The condution which must hold for this enables the values of A, B, C to be identified with -Li, -M, -L₂.

Maxwell's introduction of Lagrange's dynamical method into electro-magnetism is, as has been already stated, regarded by Poincaré as of great importance, and as he says "nous touchons ici à la vraie pensée de Maxwell."
After finding by this method the inductive electromotive forces, and the electro-magnetic forces, he proceeds to discuss Maxwell's theorems of the electro-magnetic field, and their crowning generalization, the electro-magnetic theory of light Except here and there, the treatment differs only in points of detail from that of Maxwell.

With regard to the equations of currents.

$$u = CP + \frac{K}{4\pi} \frac{\partial P}{\partial t}$$
,
&c. &c.

a difficulty is pointed out as to the specific inductive stance the first term must preponderate, and so K must be small, whereas K is generally regarded as very great in the case of a conductor It is worth noticing that this is really only a conventional means of explaining the impossibility of charging a condenser the space between the plates of which is filled with conducting substance, the true explanation is, no doubt, very different

The discussion of the experimental verifications of the electro-magnetic theory of light contains references to several lately-established experimental facts (apart from Hertz's experiments, which are reserved for special treatment) which bear on the theory For example, it has been shown by Curie that dielectrics, when tabulated in the order of increasing conductivity, are on the whole arranged (as obviously they should be) in the order of diminishing diatherinancy. Further, ebonite, which is opaque to light, is very permeable to dark radiations of longer period, which agrees with its high transparency to electrical waves

Again, it is remarked that the results of the electromagnetic theory with regard to reflections from the surface of glass and of metals lend a general support to the theory, while the disagreement in the values of the numerical constants as regards the want of magnetic permeability is referred to the frequency of the vibrations and the fact that the magnetization of the medium is not instantaneously produced

A marked feature of M Poincare's treatise is the chapter on rotatory polarization, in which he discusses the phenomena of rotation of the plane of polarized light by the action of a magnetic field. Although the essential difference between this effect and the apparently similar action of quartz, sugar solutions, &c, is pointed out, the author does not appear to lay stress on it as throwing light on the difference between their causes For example, after giving Airy's differential equations, for the propagation of the two rectangular component displacements, ξ , η , of a circularly polarized wave travelling along the axis of x, in the form

$$\begin{split} &\rho \frac{\partial^{4} \xi}{\partial \tilde{t}^{2}} = \frac{\partial^{2} \xi}{\partial z^{2}} + a \frac{\partial^{2} \eta}{\partial z^{2} \partial \tilde{t}^{2}}, \\ &\rho \frac{\partial^{2} \eta}{\partial \tilde{t}^{2}} = \frac{\partial^{2} \eta}{\partial z^{2}} - a \frac{\partial^{3} \xi}{\partial z^{2} \partial \tilde{t}^{2}}. \end{split}$$

NO. 1135, VOL. 44

can be obtained, which agrees with experiment, and after comparing the results of these equations with those of

other proposed equations, he says .-"Mais si le concordance de la formule avec l'expérience justific l'intioduction des derivées + 2 1/02201, - 21E/02101 dans les secondes membres des équations du mouvement d'une molécule d'éther, aucune considération théorique ne préside au choix de ces dérivées à l'exclusion des autres ; on ne possédait donc pas encore de théorie de la polarisation rotatoire magnétique"

This certainly seems rather too strong a statement in the face of Thomson's dynamical theory outlined in his "Electrostatics and Magnetism," and further claborated in Maxwell's treatise

Thomson's views on this subject are of the most fundamental importance, as they point to motion of, or in, the medium occupying the magnetic field as the cause of the magneto-optic effect discovered by Faraday, and to a certain structure of the substance as producing the phenomena shown by quartr, syrup, &c One of the most interesting passages of his lectures on molecular dynamics, delivered at Baltimore in 1885, is that in which he accounts for the observed results by the presence of rotating particles, "gyrostatic molecules," in the medium

It is obviously suggested by the gyrostatic investigation that it ought to be possible to explain the magneto-optic rotation in the electro-magnetic theory of light as a consequence of the presence of small magnets embedded in the vibrating medium with their axes in the direction of the ray, and therefore producing a component of magnetization in that direction. It is stated by M. Poincaré that a theory of this kind has been proposed by M. Potier, and published in the Compter Rendus The theory itself is not given, but the differential equations obtained are quoted, and are of the required form, and lead to the known experimental result 1

Maxwell's molecular vortices theory is, however, given, and certain difficulties which it involves discussed. The theoretical results of Hall's experiment are also given in theoretical results of trains experiment are also given in this connection, and Kerr's experiment proving the pro-duction of elliptic polarization by the reflection of plan-polarized light from the pole of a magnet is cited, but without any statement of the theory of the effect which has been worked out, principally by Fitzgerald. With regard to the explanation of the Hall effect by strain of the conducting film produced by the magnetic field, it has always seemed to me that it ought to be possible with proper appliances to decide the question, by experi-menting with a sufficiently powerful and uniform magnetic field

The work, it ought to be stated, concludes with an interesting chapter by the editor, M. Blondin, on experimental verifications of the theories of Maxwell This comprises the chief determinations of specific inductive capacity, Kerr's classical researches, and lastly, the interesting investigation inade by M. Rontgen of the electro-magnetic action of currents of displacement Of Prof. l'oincaré's second treatise on the experiments

of Hertz, &c. I hope shortly to give an account as a sequel to the present article A. GRAY

THE ORIGIN OF THE FLORA OF GREENLAND

LIOW the present flora of Greenland originated, is a question of great interest to British botanists and geologists, for the answer will probably help to solve the difficult problem, What was the origin of the recent flora of Britain? The flora of Greenland is so poor in species and has been so well studied that its relationship to the floras of Europe and America ought not to admit of much

from which a formula for the rotation of the plane of polarization of plane-polarized light in a magnetic field account of the present of the plane of polarization of plane-polarized light in a magnetic field account of the present of the plane of the

debate; yet we find that an active discussion is now going on among Scandinavian botanists as to its eastern or western affinities Sir J D Hooker, in his "Outlines of the Distribution of Arctic Plants." made a careful analysis of the species found in Greenland, and came to the conclusion that the relationship was more European than American, and this view seems to have been generally adopted by botanists. In a recent official report, contained in the valuable series of memoirs published by the Commission for the Exploration of Greenland, Prof. E Warming, however, has tried to show that the flora is American, and as this author has had access to fuller materials than were formerly available, his opinion will carry considerable weight Prof. A G Nathorst, a botanist especially competent to speak on questions relating to the botany of the Arctic regions and on the relation of the recent Arctic flora to the Glacial epoch, objects altogether to Prof Walming's conclusions, and, although dealing with the same materials, maintains attough desing win the same materials, maintains the accuracy of the generally accepted view as to the European relationship of the vegetation. It has certaily examines the flora in a way that has never been done before, and points to its dependence on bygone conditions. To certain of 1 Prof Nathorst's observations and conclusions I should like to draw attention

The principal result arrived at by Prof Warming was that the boundary between the American and the European provinces is formed by the Denmark Strait (the strait between Greenland and America), and not by Davis Strait as botanists have generally thought This conclusion Prof Nathorst critically examines, and so many curious and suggestive facts relating to geographical distribution come out in this examination that I may be unation to the out in this examination that 1 may be excused for referring to ceitain of them somewhat in detail. The flowering plants of Greenland include 386 species, none of which are confined to that country. Leaving out of security control to the country. eaving out of account circumpolar forms, Prof Warming finds in the list 36 characteristic western against 42 eastern species, but suggests that when the flora of Aictic America is better known the balance will probably be in favour of the western forms Prof Warming, however, includes among the eastern plants only those now living in Europe, the Asiatic-American species being classed as western on the ground that they must have entered Greenland from the west rather than from the east -a somewhat unsafe line of reasoning when we take into account former changes of climate and the local extinction of

many plants*
Prof Nathorst analyzes the list differently, and gives most suggestive tables and a map of the local distribution of the eastern and western plants in Greenland From these we find that the coast nearest to Iceland contains European forms a lone, the southern externity contains European forms and insports, while the part of the west European forms and insports, while the part of the west European forms in an insports, while the part of the west European forms in an insport, while the part of the west European forms and the part of the west European forms and the part of the west European forms and the part of the most of the form of Greenland is not entirely cut off by the Demmark Stratt, but extends eastward as far as Iceland

Prof. Warming considers that the nucleus of the present infor of Greenland represents part of the original fora, which was able to live through the Glacial epoch on the non-glaciated areas; but Prof. Nathors points out that the few non-glaciated mountain-tops must have been far too ligh for any phanerogams to cust on them, and all the lowlands were then covered with ice and snow. We must therefore consider that both eastern and western elements of the present flora of Greenland entered the country in post-glacial times. The tables of distribution

show at what points a large number of the plants entered,—they came from the nearest land, whether European or American. Whether in post-glacial times there was any complete land-connection between Greenhand and either North America or Iceland is very doubtful, but the straits collects in which was the sum of the strain of

Turning now to the British Islet, we know that a prolife temperate for a inhabited this country in pre-glacial times. We know also that this flora disappeared and was replaced by a thoroughly Arctic one, at least as far south as Norfolk, where its relics are found beneath the moraner. Then came a period when Britian north of the Thanes was covered with ree and snow, and only an in Greenland—rose above. When the ice iterated, the Artic phanerogams again spread over the country, for we find value plainary, S herbitac, S returlated, Retula mana, and I overleuring proximens in lacustrine deposits immediately above the boulder clay near Edinburgh; we have also a similar flora, with Sada polaria, S nyrvatites, and Jetula mona, in Stifflix, and even in Denonshire the state of the proper of the property of the country of the state of the property of the country of the closed with the present of the property of the country of the closed with the present of the property of the proposition of Greenland of Create India.

In Britain, however, we have now reached a later stage in the amelioration of the climate and re-settlement of the country, for the Arctic plants have either disappeared entirely or have retreated to our mountain-tops, and in their place on the lowlands we find a temperate flora now The British flora, like that of Greenland, varies according to the botanical character of the nearest land. though, as with Greenland, there is no reason, except the supposed impossibility of the migration of the animals and plants without a bridge, to imagine that during postglacial times there has been any direct connection with the Continent, save perhaps at the Straits of Dover The distribution of plants in Britain is so peculiar that I may be forgiven for pointing out to non-botanical readers that we have a southern flora opposite France, a Germanic flora on the east coast, a Lusitanian flora in the south-west, and on the extreme west there are two American plants unknown elscwhere in Luiope In the Britain of the present day I believe that we may study the re-peopling of a country over which everything has been exterminated and until we have fuller direct evidence of the stages of the process, we may safely accept Greenland and Britain as illustrating the way in which Nature works to fill gaps in the fauna and flora, whether these are caused by changes of climate, by volcanic agency, or the subinergence and reappearance of islands CLEMENT REID.

THE SUN'S CORONA

SOME little time ago Dr. Schaeberle, of the Lick Observatory, was good enough to send me the following letter.—

Allow me to call your special attention to a note of mine in the forthcoming number of the A. S.P. Publications, entitled "Some Physical Phenomens involved in the Mechanical Theory of the Cornes" I wish to say this, as far as the connection of this theory with the sur-spot period is concerned, there was not, at any time, any effort on my part to make an agreement with a transport of the part of the part of the properties of the and investible results of tracing certain observed phenomens to unexpected explanations. As you will see, the legical outcome

¹ Trans Lim Soc vol xxiii, pp 251-348 (1861), partly reprinted (with additions) in the "Maaual of the Natural History of Greenland,"

^{80 (1875)} Om Grønlands Vegetation Meddelelser om Grønland," Part 12 (1888) Ingler's botanisches Jahrbuch, 1831, p. 183

NO. 1135, VOL. 44]

of the whole matter is that, unconsciously, I have actually furnished important evidence in favour of your meteoric hypothesis.

Sincerely yours.

Sincerely yours,

I. M. Schaeberle.

Some time after the arrival of the latter I received the number of the Publications of the Astronomical Society of the Pacific which contained the arricle referred to the Pacific which contained the arricle referred to the state of the pacific pa

The point of newest interest, however, is that referred to in Dr Schaeberle's letter

Assuming eruptions most active in the sun-spot zones, and an initial velocity of 380 miles a second, he obtains the following results —

(1) All parts of a given unperturbed stream will be in a heliocentric latitude nearly equal to the latitude of the point of ejection

(2) For a constant ejective force the periodic time !
will be the same for all parts of the stream

(3) The chance of collision of a returning with an outgoing stream varies inversely as the square of the distance of the point of collision from the sun

(4) Near the sun, therefore, collisions must occur which tend to retard or stop the outgoing streams, resulting in a temporary increase in the heat of the combined colliding masses (causing a consequent increase in the brightness of the corona at such places, and at the same time rendering the coronal detail more conditived.) This heat will tend to be largely dissipated before such masses fall back into the sun, which they will then reach with comparatively small velocity and low temperature at the control of the comparatively small velocity and low temperature at the noise of impact perturbed returning streams could, of course, strike all parts of the sun's vurface. Unperturbed returning streams could, of course, strike all parts of the sun's vurface. Unperturbed returning streams will always fall within the limits of the sun-spot cones.

(3) So long as the incoming streams are very numerous, the outgoing ones will, in a great measure, be stopped, so that, after the internal f, there will be comparatively few returning streams a direct result of this state of things since there are now but few collisions, results in (1) as apparent diminution in the brightness of the corona, (2) more regular and sharply defined detail, and (3) in general a more uniformly illuminated solar surface might be expected, when there are but few or no returning streams expected, when there are but few or no returning streams of the surface of the surface

(6) If the ejective force is such as to make / about five years, a complex cycle of changes will take place in the time 21, and after the same manner as is observed in the sun-spot cycle. It is rather remarkable that the aphelion distance of the streams corresponding to this value of it is nearly the same as Jupiter's distance from the value of it is nearly the same as Jupiter's distance from the may have more to do with the regularity of the period than the assumed constant force of jection. The initial velocity required to just carry a particle from the sun to jupiter is but little less than a parabolic velocity. For an initial parabolic velocity, Suturn, alone considered, would, on the same lypothesis, cause a complete cycle of would, or the same lypothesis, cause a complete cycle of years, and Neptune in one hundred and those years, and Neptune in one hundred and the property of the comparatively insignificant planets inside of the

orbit of Jupiter would cause minor variations, corresponding to cycles, which, even for Mars, would be of less than two years' duration

(7) The chance of the earth passing through one of these outgoing streams, which have a mean latitude of 15°, 18 less than it is for an incoming perturbed stream

(8) A phenomenon similar to the observed zodiacal light would result from the projection of many such streams in space, and the observed extent of this light proves that the matter which causes this illumination extends to greater distances from the sun than the earth's distance.

It is evident from the foregoing that the complete statement which is to appear shortly will be looked forward to with interest

For myself, I am glad to think that the views I put forward in the concluding chapter of my "Chemistry of the Sin" "ull now be looked at from a new point of view. The Sil show what the "falls" which take the first place in my scheme, and the second in Dr. Schaeberle's, really are certainly I have seen no cause lately to alter the view I expressed in 1897, that the primary cause of solar disturnance is the desient of matter on the photosphery. Vis.

NOTES

ON Monday the Prince of Wales presented the Albert Medal of the Society of Arts to Mr W H Perkin, "for his discovery of the method of obtaining colouring matter from call tar, a discovery which led to the establishment of a new and import ant industry, and to the utilization of large quantities of a previously worthless material," and to via Frederick Abel, "in recognition of the manner in which he has promotel several important classes of the arts and manufacture of by the applica tion of clemical science, and e-pecially by his researches in the manufacture of non and steel, and so in advicedigment of the great services he has rendered to the viate in the provision of improved war material and as Chemist of the War Depart ment." The medal awarded to Mr. Perkin was for the year 1850, that to Sir Frederick Abel was for the years.

WE are glad to bear that in consequence of the deputation which waited upon Sir Michael Hicks Beach on June 5, the Board of Trade have registered the British Institute of Preventive Medicine as a limited liability company, with the omission of the word "himted."

It seems as if the introduction of large engineering views may soon produce a very marked effect upon the future of Egypt Mr Willcocks, one of the Inspectors of Irrigation, has communicated an interesting letter to the Times, from which we select the following remarks on the engineering importance of Dongola .- "The summer supply of the Nile is lamentably deficient for the existing cotton and sugar cane crops of Egypt, so that all extensions of these valuable crops are out of the question under existing conditions The Nile Valley in Nubia is emmently suited for storage of water, but up to the present all projects for storing the muddy flood waters of the Nile below the junctions of the Blue Nile and the Atbara have been condemned, as the construction of solid dams would have resulted in the silting up of the reservoirs themselves. This difficulty has disappeared now that it has been discovered that open dams can be constructed which will allow the muddy flood waters to flow through, and store the clear winter supply for use in summer The construction of these dams has been rendered possible by the great success of Stoney's patent roller-gates, which can be worked under heads of 70 feet of water on a scale sufficient to pass the full flood supply of the Nile. At any time now Egypt

can construct a reservoir in its own territory by building an open dam at the head of the Assouan Charact. If, however, Egryt were allowed to occupy the Nile Valley as far an Dongola, the reach of the rever above the Wally Halfa Catanet would provide the necessary testroolis, and the Phile immersion difficulty would be at an end. So far the summer supply needed for Egryt proper. If the Soudan stell' is to be developed, it will only be necessary to construct solid dams at the heads of the Hypon Falls and Fola Rapids, and thus secure the Victoria and Albert Nymara Lakes as magnificent reservoirs. These reservoirs would not only secure Egypt and the Soudan from drought, but would not only secure Egypt and the Soudan from drought, but would about. The With Opin dain, secure Egypt and the state of the stream, so that the viling up of the reservoir would be out of the ossetton, leaving alone their creat size."

WE very cordially congratulate Sir G B Airy (the ex-Astronomer Royal), on the completion of his nineticth year. A distinguished company assembled at the White House, Greenwich Park, on Saturday lest, in honour of the occasion.

PROF. ADALBERT KRUEGER, Director of the Observatory of Kiel, has been appointed Prof. Schonfeld's successor at Bonn

DR FELIX has been appointed professor in the University of Leipzig

THE Council of the Yorkshire College, Leeds, have appointed Mr V Perronet Sells, New College, Oxford, to be Extension Lecturer in Science

A PROJECT is in the six for the erection of an Observatory on Mont Blanc. M Janssun made an appeal list year for support in this undertaking, and on Monday at the Academy of Sciences he announced that his appeal had been heard. He has obtained the support of M Bischoffishim, Prince Roland Bonaparte, Baron Alfred de Rothschild, member of the Academy of Fine Arts, and M. Effel

THE annual meeting of the Institution of Mechanical Engineers was opened on Tuesday at Liverpool

SANITARY science has, during the last month, lost one of its pioneers, in the person of Dr John Sutherland, whose record of work in the domain of santtation since 1848 has been of a marvellous character. In 1848 he entered the public service under the first Board of Health, and continued to be employed under the Home and Foreign Offices till the year 1855 During this time he conducted several special inquiries-notably one into the cholera epidemic of 1848-49, which is even now frequently referred to 112 was the head of a commission sent to various foreign countries to inquire into the law and practice of burial. He represented the Foreign Office at the International Conference, held at Pans in 1851-52, for regulating quarantine law In 1855 he was engaged at the Home Office in bringing into operation the Act for abolishing intramural interments, a task which he had undertaken at the request of Mr Walpole He was also doing duty in the reorganized General Board of Health, under the presidency of Sir Benjamin Hall, when, at the request of Lord Palmerston and Lord Panmure, he became the head of the commission sent out to inquire into the sanitary condition of our troops engaged in the Crimean War He found in Miss Florence Nightingale a devoted coadjutor in regard to the hospitals. Dr Sutherland took an active part in the preparation of the report of the Royal Commission (of which he was a member) on the sanitary state of the Army, dated 1858, and also of the report of the Royal Commission on the sanitary state of the Army in India, dated May 19, 1863. Both of these were of vast importance to the welfare of our soldiers, and most of the recommendations con-

tained therein have been carried out. One of these was the appointment of the Barrack and Hospital Improvement Commission, with Mr Sidney Herbert, M P, as President, and Cantain (now Sir Douglas) Galton, Dr. Burrell, of the Army Medical Department, and Dr. Sutherland as members. By this committee every barrack and hospital in the United Kingdom was visited, and its sanitary condition reported upon Defects were brought to light and remedied, and the health of the troops consequently much improved Subsequently Dr. Sutherland and Captain Galton visited and made similar reports on the Mediterranean Stations, which at that time included the Ionian Islands All these reports were presented to Parliament, and a reference to them will show the vastness of the work undertaken In 1862 the Batrack and Hospital Improvement Commission was reconstituted, and all sanitary reports were submitted to the committee and reviewed by them, and suggestions for improving Indian stations prepared. This continued up to the time of Dr. Sutherland's retirement, on June 30, 1888 In 1865 he again visited Gibraltar and Malta, and made an independent and special report on the outbreak of epidemic cholera at those places In 1866, Dr Sutherland in communition with Mr R. S. Ellis, of the Indian Civil Service, Dr Joshua Paynter, of the Army Medical Department, and Major (now Lieutenant-General, (B) Fwart, R.E, visited Algeria, and reported on the causes of reduced mortality in the French army serving in that country, with a view to seeing what of the conditions in force there would be applicable to Her Majesty's troops serving in India and other warm climates. The value of the recommendations made by him and his colleagues will be better understood by a comparison between the vital statistics of the army prior to the time of the Crimcan War and those of the present date than in any other way

MR WILLOUGHBY SMITH, who had played an important part in connection with submarine telegraphy, died on July 17. He was born in 1828, and in 1848 entered the service of the Gutta-Percha Company, and superintended the manufacture and laying of the first submarine cable. The Times gives the following account of his subsequent career. In 1864 the Gutta Percha Company became merged in the Telegraph Construction and Maintenance Company, and Mr Smith remained with the company as chief electrician and manager of the gutta percha works until his retirement through failing health in 1887. In 1866 he was electrician-in-charge, being on board the Grea Eastern during the laving of the first successful Atlantic cable. and the recovery and completion of the cable that had been lost the year before Mr Smith was President of the Institution of Electrical Engineers in 1887, before which Society, as well as before the Royal Institution, he read many interesting and valuable papers Amongst these was one on his discovery of the effect of light on the electrical quality of selenium, and another on his researches in volta and magneto electric induction.

Mr DANIEL MACKINIONI, F.G.S., died at Birkenhead las week at an advanced age. He was the author of a work on "The Scenery and Geology of England and Wales," and his researches on certain traces of the glanal epoch were well known to geologists. In recognition of his services to geologists seence, the Geological Society presented him in 1886 with a great from the Lyell Fund.

MR EDWARD STANFORD has published a pamphlet on "The Spread of Indicens; its Supposed Relations to Atmospheric Conditions," by the Hon R. Russell. The following are some of the author's conclusions as to the conditions which give rise to influenza, and permit it to be spread. Influenza is a disease caseed by exceedingly minute merches, arming from extensive areas of must hor produce in and in Central Asia, China, or Sibarian. The minuteness of the microbes or their spores a showbuy their

easy transmissibility, and the large number of persons capable of being infected by a single case in a large room, most persons probably requiring many virulent organisms to be inhaled in a short time before the resistant power of the blood is overcome This microbe, like that of cholera, multiplies with great rapidity, and probably soon produces sufficient poison to terminate its career in the body, but not before multitudes of spores or microbes have been given off by the breath. Given the original conditions of rainfall, soil, and high temperature, the certain result is the development of inconceiva ble multitudes of microbes and spores, one species of these is capable of planting itself and living in the tissue and blood of man, of which the temperature is probably near that to which it has been accustomed under the summer sun in wet and drying ground The somewhat rare and occasional visitations of influenza may he due to at least two or three causes-first, the occurrence of nnusual rainfall and favourable summers , second, the prevalence of air-currents from the drying area towards inhabited places, third, adequate communication between these infected places and the towns of Russia, whence progress is rapid towards Western Europe The wind has no influence that can be verified in the transportation of influenza. As for the means of prevention, Mr Russell thinks that measures of disinfection and isolation of the earliest eases, and rules at ports and landing places similar to those employed against cholera, would probably prove of the greatest service Inland, every locality should isolate and disinfect its first cases

PROF. LANGLEY, the Director of the Smithsonan Institution, in own in this country J n-year of his recont researche, referred to in our last number, we learn that Mr. Maxim is boulding at "flying machane," with which a series of experiments is contemplated, it is now being constructed at Crayford, and is nearly ready for launching. It will be propelled by a light screw making 350 serviations a minute. The motive power (it is reported) is upplied by a perroleum condensing engine weighing eighteen hundred pounds, and capable of rasing a forty thousand pound load. The real suspending power will lie in an enormous keit measuring it to feet long and 40 feet wide

THE following passage occurs in the Report of the Medical Officer of Health of the parish of St George, Hanover Square, for the five weeks ending July 4, 1891 -"I have calculated the death-rate of the parish for the past month on the eensus population of 1881, and not on that of 1891, for the following reasons .- The census population of the parish in 1871 was \$9,758, and that in 1881 was \$9,573, I have no reason to believe that there was any serious inaccuracy in either of these enumerations, so that the population of the parish was practically stationary during the ten years from 1871 to 1881 The enumerated population in 1891 was only 78,362, showing as apparent decrease of 11,211 (or one-eighth of the population) since 1881 I know of no reason whatever for any such decrease, and do not believe it has taken place. The census was taken of the persons sleeping in the parish on the night of Sunday, April 5, a day which had two serious disadvantages, the first being that it was a Sunday, a day on which many people in this parish are out of town, and the second that it was the Sunday after Easter, and that large numbers of people had not returned to town from their Easter holidays. I therefore consider that the enumeration of the population of the parish this year is of no value for statistical purposes, and in estimating the birth-rates and death-rates, shall continue to use the census population of 1881, until a fresh and more correct enumeration shall have been made, which will, I hope, be in 1896" This is rather serious. What have our eensus authorities to say on the matter?

NO. 1135, VOL. 44]

An earthquake was experienced at Evansville, Indiana, on the 26th inst The shock was so great as to create a panic in several places of worship. Considerable damage was done to property. The direction of the oscillations was from north to south

THE weather prospects in the North-West Provinces seem to be improving Beneficial rains have commenced to fall, and a famine is therefore less probable than it was The distress among the ryots is, however, great, and the Government of India has voted a grant of \$\int 10.000 for their relief The follow ing telegram was read by Sir J. Gorst, on Tuesday night, in the House of Commons -" There is an improvement in agricultural prospects and development of monsoon season. There has been good general rainfall throughout the country, except in part of Madras, the Carnatic, and Upper Burmah, in consequence of which there is no present cause of anxiety in Northern India Strong monsoon blowing West Coast More rain imminent in Punjab and Rajpootana, where fodder famine has been arrested by rain Crop operations in Northern India generally progressing satisfactorily, and there is no present cause for anxiety in North-West Provinces and Oude "

Tits Technical Education Committee of the Kent County Council has placed £3000 at the disposal of the South-Eastern Counties Association for the Extension of University Teaching, for courses of lectures suited to agricultural and rural populations in small towns and villages throughout the country.

Tits Accademia delle Scenze dell'Issuituo di Bologno offens a godi uncidal of cool ine value (about 4,0), the Adim Prae, "to the author of a memor which, based on certain data of chematry, or physic, or applied mechanic, shall indicate new and really practical systems or new apparatus for prevention or extinction of fees." The memors may be manucerpin in Italian, and the statement of the statem

I is most recent addition to Prof Flower's excellent sense of specimens illustrative of sological structure placed in the eartance-hall of the Natural History Museum is a test of nine-end obsections prepared by Mr. O. Redwewd to I blustrate the visions on the deep plantar tendons of the bard's foot. With the help of these preparations, the student will have little diffi-culty in anderstanding the mysteries of the fleer foreign ballions and the fleers preforms displacement, page which two municles, as has been shown by Sundeval, Garrod, and Forbes, so much depends in the classification of birds.

It would seem that the present interest in agracultural instruction comes none too soon. The Aquicultural Gasatte of New South Wales gives an account of a new industry—the export of butter to this country, and adds, that the Minister of Mines and Agraculture has approved of the establishment of a travelling dairy to impair instruction to the settlers in relation

THE same number contains articles on the grasses and weeds of the colony, and notes on economic plasts and weeds, besides information of what some people consider as of a more "practical" character, touching profitable cows and pigs

THE uthration of waste products is the order of the day. An interesting article on this subject, in relation to breweries, in the Breweri Guardian, calls attention to the utilisation of the carbonic and gas produced in the fermentation of sugar "On an average, English beer may be considered to contain 5 per cent, of alcohol, and as, in the fermentation of sugar, the

weight of carbonic acid produced is almost the same as that of alcohol (the exact proportions being 48'9 of carbonic acid to 51'1 of alcohol), there must have been 500,000,000 pounds of carbonic acid produced in our breweries The specific gravity of carbonic acid is 0.1524, and therefore a simple calculation shows that the above weight is equal to 25,000,000,000 gallons -a volume it is almost impossible to realize, such a volume would require a space one mile square and forty yards high to contain it. It is now proposed to utilize the greater portion of this large quantity of carbonic acid. The process by which this is to be done has been tried for some little time past in St James's Gate (Guinness's) Brewery, Dublin , and Sir Charles A Cameron has reported very favourably on it. The following are the conclusions at which he arrives after a most careful examination of the process -(t) An immense quantity of carbonic acid is produced in breweries, and is at present wasted, (2) a large proportion of this gas could be condensed to liquid at a cost not exceeding he per pound, but probably less than ld per pound, (3) the process of liquefying the gas is successfully carried on at Guinness's Brewery, Dublin , (4) the liquefied gas prepared at Guinness's Brewery is perfectly free from any peculiarity of flavour or odour, (5) the carbonic acid produced at soda-water works costs about 4d per pound, (6) it is safer, and in every way more desirable, to use in beverages carbonic acid derived from a food substance, such as grain, than from mineral sources: (7) the uses of hourd carbonic acid are numerous. important, and increasing "

AMONG the plants shown at the meeting of the Royal Botanic Society on Saturday last was a museum specimen of one which had lately died in the Gardens-a victim to the late severe winter This was one of several specimens of the East Indian or white mangrove. Avicennia nivea, sent to the Gardens by the late Duke of Buckingham when Governor of Madras For some years past these plants had flourished amazingly, thanks to the near approximation to their natural condition attained by keeping them in a very wet state and watering only with seawater Under these circumstances they threw up from the roots a number of offsets, or upright adventitious roots, of from 10 inches to 12 inches high, and half an inch thick In a space of 2 feet square as many as eighty appeared, looking like so many rakes standing up out of the water, and keeping as near as possible the same height above the surface. The only explanation, so far, has been that offered by the Secretary, Mr. Sowerby. In its native state the trees form a fringe along the sea-shore and estuaries of great tropical rivers, lining the banks with a dense and impenetrable mass of vegetation, pushing itself further and further into the river or sea, and leaving behind the dry land it has reclaimed. In such a position these curious rootlets must be an immense advantage to the plant, enabling it to retain all the debris washed to the sides, and at the same time preventing the soil between the roots from being carried away by floods, &c The plants of this species now growing in the Gardens are the only ones alive in this country,

A MOST interesting report of a journey taken along the frontier of the British Protectorate of Nyassaland by Mr J. Buchanan, C M.G., Acting Consul at Nyassa, appears in the Kew Bulletin for July.

FROM the Meteorological Observations at Sydney for January 1891, just received, we learn that the temperature was 2° higher, the humidity 2 4 less, and the rainfall 0°87 inch greater than that of the same month on an average of the preceding thirty two years.

THE Indian Government has just issued a "Contents and Index of the first twenty volumes of the Records of the Goological Survey of India, 1868-87" Considering the important work done by this Survey, the index will be of great value to geologists. It consists of 188 pages

NO. 1135. VOL. 44]

THE pamphlet entitled "A Summary of the Darwinian Theory," which was noticed in a recent issue (1914, 6, p. 247), has been printed for private distribution. The author, Mr. Pascoc, will supply a copy to any person interested in the subject on application to him at 1 Burlington Road, W

A new and cheaper edition of the translation of vol. i, of Wesmanns' "Essays upon Heredity and Kindred Bologora Problems" is announced for immediate publication by the Clarendon Peres; and we understand that vol. u is in the price, and will consist of four additional essays, and a preface by Prof. Westmann.

Petermann's Mitteilungen for July contains an article on Zante, with an original map, based on the English Admiralty chart, by Prof Partsch

An official notice has been issued concerning the chariable foundation instituted by the Sitters Froetich at Venna for subsidiating persons distinguished in science, art, or literature. Persisons and donations are to be granted to duly approved applicants: Applications should be addiessed to the Trustees (das Caratonium), and transmitted to the President's office of the Common Connell of the City of Vienna (an dar Prandalbureau des Wiener Gennelentwishe Nues Kathasu) before August 13, 1891, through the I and K. Austro-Hungarian Embasy in London, 18 Befgaree Square, SW, where particulars of the terms and conditions of the foundation deeds, &u., can be obtained.

FURTHER details concerning the new volatile compound, iron carbonyl, Fe(CO), are published by Messrs Mond and Quincke in the current number of the Berschie. It appears that as early ns November last year they succeeded in volatilizing small quantities of iron in a stream of carbon monoxide, and recovering it again in the form of a metallic mirror by passing the gaseous product thro heated tube. The best results are given when the iron is obtained by reduction of ferrous oxalate in a stream of hydrogen at as low a temperature as possible, very little exceeding 400° C , and allowing to cool in the stream of hydrogen to 80°. When carbon monoxide is led over the finely divided iron thus obtained, the issuing vapours are found to colour a Bunsen burner pale yellow, and if they are passed through a glass tube heated to a temperature between 200 and 350', a mirror of metallic iron is deposited. If the tube is heated to a temperature superior to 350°, instead of a nurror a black flocculent deposit is obtained. containing carbon in addition to iron. The metallic mirror dissolves readily in dilute acids, and the solutions give all the reactions of iron A quantilative analysis was made of one such mirror, and yielded almost theoretical numbers for pure iron. The black flocculent deposit was found in two cases to contain 79 30 and 52 78 per cent of carbon respectively. The reaction, however, proceeds only very slowly To give some idea of this, Mesers Mond and Quincke state that after six weeks continued treatment of twelve grams of iron with carbon monoxide only about two grams had been volatilized. As the action becomes very slight indeed after treatment for some hours, the operation was interrupted at the end of every five or six hours, and the iron reheated to 400° in a stream of hydrogen, after which the reaction proceeded again as at first. It is calculated that the average amount volatilized was about two cubic centimetres per litre of carbon monoxide. This great dilution has of course rendered it very difficult to ascertain the composition and properties of the substance. Its composition has, however, been determined by absorbing the vapous obtained during eight to sixteen hours in mineral oil of boiling point 250°-300°, which after numerous experiments has been found to be the best solvent for it, and heating the solution thus obtained to 180°, when it becomes black owing to the separation of metallic iron, and carbon monoxide is evolved. Determinations of the amount of separated iron and

the volume of carbon monoxide obtained in five such experiments gave for the proportion of molecules of CO to one atom of iron the numbers 4 14, 4 03, 4 15, 4 26, and 4 04 respectively Hence there can be very little doubt that the compound is represented by the formula Fe(CO)4, analogous to the nickel compound obtained last year, Ni(CO)4. As regards the relation of the compound to the processes of iron and cementation steel manufacture, the authors are of opinion that, although they have been unable to prepare it at temperatures between 150° and 750°, still it is quite possible that it may be momentarily formed at such temperatures. but soon Immediately dissociated

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (Macacus cynomolgus) from India, presented by Mr G Stevenson Macfarlane, a White fronted Capuchin (Cebus albifions) from South America. presented by the Earl of Carnaryon, a Silver-backed Fox (Canis chama 8) from South Africa, presented by Mr Max Michaelis, a Ring-tailed Coats (Nasua rufa) from South America, presented by Mr. J. Smalman Smith, two Rough Foxes (Canss rudss) from British Guiana, presented by Mr. G H Hawtayne, C M Z S , two Pennsylvanian Buzzards (Buteo benneylvaniens) from North America, presented by Sir Walter Hely Hutchinson; a Barn Owl (Strix flammea), British, pre sented by Mr. E Hart, F Z S., a Tigrine Cat (Felis tigrina), two Spotted Cavies (Calogenys paca), a White-hpped Peccary (Dicotyle labiatus), a Red and Yellow Macaw (Ara chlor optera), a Blue and Yellow Macaw (Ara grarauna), two Orange-winged Aniazons (Chrysotic amazonica), two West Indian Rails (Acamides cayennensis), a Martinique Gallinule (Ionorms martinicus) from South America, a Golden Agoutt (Dasyprocta agutt), three Crested Curassow (Crav alector) from Guiana, a Hawkheaded Parrot (Direptyus accipitrius), a Common Trumpeter (Prophia crepitant) from Demerara, deposited, an Azara's Agoutt (Dasyprocta azara) from South Brazil, purchased

OUR ASTRONOMICAL COLUMN.

OBSERVATIONS OF SUN-SPOIS AND FACULE, -- Comptex rendul for July 13 contains the results of observation of sui-spots and faculte, made by M Marchand, at Lyons Observation, during the first six months of this year. The following table expresses, in millionths of the sun's visible hemsphere, the surface overered by spots and facult, during this period

1891		Surface covered	Surface cove
January		by spots	by faculæ
rebruary		385	12 5
reoruary		503	20 7
March		265	15 9
April		726	25'4
May		670	22't
June		968	29 7
1	Total	2517	126.2

These figures demonstrate the increase in solar activity which must have been noted by all observers
The total spotted area must have been noted by an observers the total spotted area of 3517 millionals is made up by 65 groups Duning the whole of 1890 the spotted area given by 43 groups was only 3760 millionths. Since the end of March not a single day has passed without a spot being seen on the sun. With regard to distribute the state of the sun with regard to distribute the state of the sun with the state of the sun with regard to distribute the sun with the sun w tion, 40 groups have appeared in the northern hemisphere as against 25 in the south. These occurred most frequently between the latitudes ± 20° and ± 30° At the same time 22 groups the latitudes ± 20° and ± 30° At the same time 22 groups have had latitudes between 10° and 20° (with four groups below

is a list action between to and 20 (with noir groups below 15%), thus indicating an approach to the equator.

The measures of faculte give similar results. The two zones from 20° to 30° are the richest, and those from 0° to 10° the poorest. The total numbers are sensibly the same in both poorest. The total numbers are sensitily the same in boun-hemispheres. There is, however, a slight supersority in relation number in the northern hemisphere, but less marked than during 1890. The total surface covered by facults in 1890 was 1937 millionths of the sun's visible disk, so that the figures now given indicate a considerable augmentation. It is also worthy of note that the results obtained for apots and faculæ show a certain parallelism, secondary minima in March and in May occurring each case

STARS HAVING PECULIAR SPECIES. -- In a communication to Astronomische Nuchrichten, No 3049, Prof. Pickering notes that a Group II star situated in Sagitarius (R. A. 19h 51 8m, that a Group II star situated in Sagittarius (R.A. 19h 518 m., Decl. - 42°7, 1900), having exhibited bright hydrogen lines in its photographic spectrum, was suspected of the variability of which this appearance is a characteristic. Measures of photo-graphs of the star taken on different dates proved that the apposition was a correct one, and indicated a variation between the magnitudes 9 1 and 13 1.

the magnitudes 9 1 and 13 1.

The photographic spectrum of the star S.D. - 12 1172 (R.A. 5h. 22 9m., Decl. - 12 46), mag 9 2, appears to be the same as that of a planetary nebula as regards the positions of lines, but it differs in the interesting fact that the H_B hydrogen line (F) is unusually strong in comparison with the nebula line at \$ 500.

is unusually strong in comparison with the nebula line at \$ 500. I was more stars having specia assinly consisting of bright lines there stars in Cypnus discovered West Carlotte and Cypnus discovered West Carlotte and Cypnus discovered West Carlotte and Carlotte and Carlotte and Fan Stars in the lossinon R A 13h 36 jm , Decl = 66° 55° (1900) The number of stars of the Wolf Rayet type is thus brought up to thirty-

THE INSTITUTION OF NAVAL ARCHITECTS

THE first London summer meeting of the Institution of Naval Architects was held on Thursday, Friday, and Saturday of last week During the thirty-one years that the Institution has existed, it has only held five summer meetings. The first of these was in Glasgow, and was highly successful, but it was not followed by another summer meeting until the year 1886, when the attractions of the Liverpool Exhibition were sufficient to cause the Council to arrange a second meeting for that year in the second city of the kingdoin. The Newcastle and Glasgow Exhibitions followed in the two succeeding years, and the members accordingly were summoned to the banks of the Tyne and Clyde All these meetings were successful in every respect, not only in adding to the membership of the Institution, but in the valuable papers contributed to the Transactions, and the interest of the various excursions. In the I ransactions, and the interest of the various excursions. In spite of this, no summer meeting was held either in 1889 or 1890, in which years there were but the single three days meeting in the spring. That has been conclusively proved not to be sufficient time for the conduct of the business of the not to be sufficient time for the conduct of the nusiness or true year, and at the last spring meeting it was amounced that in future two meetings would be held every year—the first to be the usual spring meeting, which always takes place in London, and the second to be held in the summer, either in London or clewhere. The success of the meeting just held strongly supports the widom of this decision

There was naturally not so long a list of papers on the pro-gramme as there is at the spring meeting, for allowance had to be made for the excursions. With the latter we are compelled to deal very briefly on account of pre-sure on our space, and we will therefore say a few words upon them at once, before pro-ceeding to notice the papers. On the first day, Thur-day, the 23rd inst, the afternoon was devoted to the Royal Naval 230 mis, the attention was devoted to the Royal Naval Ex-hibition, and in the evening there was a dinner, at which Lord Brassey presided, the absence of the President, Lord Ravens-worth, being eaused by a domestic sorrow. On the Friday afternoon the excursion was to the shippard of Samuela Brother, atternoon the excursion was to the shippart of Samuela around, at Poplar, and to the Thames Ironworks at Blackwall. The P and O Company also gave a luncheon, in the Albert Docks, on board the Carthage At Samuelas' the two second-class cruisers H.M. SS. Sappho and Scylla are in course of construction, and give quite a welcome air of busile and activity to the Poplar yard, not long since a scene of what many thought to be permanent stagnation These ships are 3400 tons each, and be permanent signation These ships are 3400 ions each, and opool indicated horse-power. A large amount of armour-plate bending and machinery is now going on in this yard, and the machine tools were examined with much interest by many of those members to whom such work was new. At the Thames Ironworks there are also two ships in progress for the Royal Navy. These are the cruisers Grafton and Theseus. The latter name brings up stirring memories of another noble ship built in years past at Blackwall. The new steel Theseus is,

however, a very different craft from Nelson's old flag-ship. She and her satter-vessel the Grejron are each of 7350 tons displacement, and have engines which will develop 12,000 indicated the state of the state of

those who winder to return to London by water were enabled to do to The three great engineering firms, Penns, Maudilays, and Humphrys, also threw open their works to the inspection of members during the meeting with the proceedings at the two morning sittings of Thursday and Friday, during which the two morning sittings of Thursday and Friday, during which six papers were read and discussed, of which the following is a -Ships of war, by Sir Nathaniel Barnaby, K C B.; on the alterations in the types and proportions of mercantile vessels, together with recent improvements in their construction and depth of loading, as affecting their safety at sea, by B. Martell, Chief Surveyor of Lloyd's Register of Shipping, centre and wing ballast tank suctions in double-bottom vessels, bentre and wing curisist tank sactions in double-outloin vessels, by G. R Brace; some notes on the history, progress, and recent practice in manne engineering, by A. J. Durston, Engineerin-Chief to the Royal Navy, progress in engineering in the mercantile marine, by A. F. Seaton, on the weak points of steamers carrying oil in bulk, and the type which expertence On the meeting being opened, Lord Ravensworth, the Press-On the meeting being opened, Lord Raviensworth, the Press oftent of the Institution, who occupied the chair, proceeded to desire the control of the control of the control of the real at the last meeting. The gold media is not given to members of Council, so that some of the papers send at the Brandy's paper brought forward some of the most values fea-tures in the history of war-ship design during the thirty-one sears which have elepted since the Insuitation was founded. An interesting fact noticed was that our earliest armour-clad, the Warrior, and our latest, the Kamillies, were of exactly the same regirence of the Warrary between the content of the warrary between the warrary betwee thick , her coal endurance is 5000 knots as against the Warrior 1210 knots, her weight of broadside is 5500 pounds, as against the Warrior's 1918 pounds. These figures well illustrate the progress made in the science of war ship construction, and the advance also extends to less desirable elements. for the cost of awahea axis extends to leas desirable elements, for the cost of the hull and enquires alone of the english first-class battle-ships and apacee, whilst the liVurror cost £35,000. It may be of interest to our readers it we add that the cost of a first-cash battle ship at the legimning of the century was about £70,000. The addi-tion of machinery and other improvements brought the cost of the 121 gun screw three-deckers, which followed the Crimean War, up to close upon a quarter of a million The armour alone of the Ramilius has cost exactly the same amount as the Natural of the Kannilitte has cost exactly the same amount as the Natural History Museum at South Kensington Bearing these facts in mind, it will be interesting to remember that Lord Brassey has laid down, in the programme of shipbailding he would propose for the next five years, the number of first class battle-ships as ten; in addition to an amounted coast defence vessels, six armoured rams, forty crusers of the first class, thirty look-out ships, and fifty torpedo gun vessels. class, thirty look-out shaps, and fifty torpedo gun veseds. Nothing is said about the smaller torpedo dar, albough a first-class (toppedo bast co-ts nearly as much as a forty-gan first-class (toppedo bast co-ts nearly as much as a forty-gan are, bowever, not so moderate as Lord Brassey; and Admiral Sor John Hay said, during the discussion on Sir Nathanide to the state of the said of the state of the said of the involved in the carrying out of such a programme as this, they are not so great, compared to the corresponding expenditure foreign Powers in terms of the value of the commerce which the ships produced would have to protect. Admiral Six Edward Free-mantle, Lord Brassey, Sir John Hay, Mr. Wigham Richardson, the Director of Naval Constitution (Mr. W. H. White), Sir

NATURE

horse-power per ton of machinery had also reached 7.5 The eapacity of boilers per indicated horse-power was 2.17 cubic feet, the heating surface per indicated horse-power 2.6 square tect, the heating surrace per indicated noise-power 2 square feet, the horse power per square foot of grate 9:41 units, and the coal consumption per indicated horse power per hour 2 811 pounds. Looking back over the twenty-two years that have clapsed since the Hercules was tried, and remembering the stringent and limiting conditions under which war ship engines were then designed, one cannot but be struck by the remarkably successful results attained with the engines of the Hercules No succession results attained with the engines of the December 100 doubt this was due to the extraordinary pains taken in the design and manufacture of the engines of Her Majesty ships inthose days. The introduction of more complex machine tools in the workshop has enabled much of this minute care and finish to be dispensed with, and the advances in metallurgical science have put has yet exceeded, or, we believe, ever will exceed, the beauty and accuracy of the noble examples of the mechanic's art constructed at the Greenwich shops under the direction of that prince of engineers, the late John Penn At the same time we gladly acknowledge that the general average of all engines has im-mensely advanced, and is still advancing, both in design, material, and finish. The whole of these three qualities are due to a wider and fifth I he whose of these three quanties are the to a whose spread of that knowledge of scientific principles upon which the mechanical arts are founded. The manual skill of the handicraftsmnn has not increased, on the contrary, it has deteriorated as inechanical contrivances have superseded the old hand opera-

From this digression we will return to the table in Mr Durston's paper, and take one more example This shall be the Purson's paper, and take one more example Internal ne the Repail Oal, a visiter of the Kamillier before mentioned, and one of the eight monster line-of hattle ships now in progress—the bugget war ships ever yet designed Laird Brothers, of Birkenhead, are the contractors for the Repail Oak She has the vertical triple compound engines and ordinary return tube boilers of the present day. The indicated horse power is put down at 13,000, but will doubless be much more, the steam pressure being 155 pounds per square meh, and the paton aprecé of 18 feet to the properties of the propert are made, a matter of conjecture, but there is every reason to anticipate it will approximate to that of the best performances recorded for Her Majesty's ships-namely, about 2 pounds of fuel recorded for Her Maşeniy's shaps—namely, about 2 pounds of feel per hour per mideate thore power developed with natural draught In taking this figure, however, we are somewhat unfair to be earlier 600% ergente on forced draught, a condition under which the fuel consumption would be much higher. What may be the fuel consumption of Her Majesty's ships under forced draught we have no means of knowing. It should be remembered that, to the Royal Navy, the steam generated in the main holters is used for the many auxiliary engines also, but the indicated horse-power of the main engines only is taken. This manifestly puts the engines of Her. Majesty's ships at a considerable disadvantage in the matter of fuel economy when comparison is made with mercantile engines If we had to summarize the lessons taught mercantile engines If we nad to summarize the lessons taught by Mr. Durston's tables in few words, we should say the steppingby Mr. Durston statues in tew words, we should say the stepping-stones to advance in marine engineering have been multi-tube builers, compound surface condensing engines, and forced draught The latter is still in that state of popular disfavour which seems to be the natural condition of all innovations on established practice, but it will yet make its mark, and lead engine-designers to higher results, whilst it will drive them to more perfect work

to higher results, whilst it will drive them to more perfect work.

Mr Seaton is well known as one of our best marine engineers, and is, moreover, a whiled writer, with a special talent for communicating his ideas through the medium of the pen That is well proved by he contributions both in the shape of memoirs to technical Societies and also by his well-known work memoirs to technical Societies and also by his well-known work on the marine engine. Unfortunately for the literary side of his on the marine engine, the continuated properties of the contract of the contra

¹ The indicated horse power of the Santegnes, the big Italian war-vessel, is stumated to be a zooo. This is the lurgest power yet designed for any ship. There are four sets of engines, two for each propeller.

NO. 1135, VOL. 44]

anxious to fulfil his promse to contribute to the proceedings, and has evidently done the best time would allow. His paper is a good illustration that "there is always plenty of room at the top," good illustration that "there is always plenty of room at the top," in the engineering, as in all other professions; but it does not call for any extended notice here. The same thing may be said of Mr. Eldridge's paper, which dealt mustuley with technical details It is, however, a distinctly valuable contribution to the Tensacions of the Institution, and may be studied with advantage by all navul architects who may have to design steamers for covering periodium in bulk—results that are fast growing in the contribution of the covering that the contribution is the contribution of the covering periodium in bulk—results that are data growing in importance and numbers

The meeting terminated with the usual votes of thanks.

SEVENTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY

THE arrangements for this Congress—which will be opened by the Preadent, HRH the Prince of Wales, on Monday, August 10, at the first general meeting at St Jaine's Hall, when short addresses will be given by some eminent foreign

hygienists—are now in a very complete state

We may mention that the previous Congresses were held in
Brussels, Paris, Turin, Geneva, The Hague, and Vienna, at the last of which it was resolved, on the invitation of the Sanitary Institute and the Society of Medical Officers of Health, that the next Congress of the series should be held in London in the

present year

Besides the Permanent International Committee, to which a number of additional members have been attached for the pur pose of this Congress, the executive consists of an Organizing Committee, with Sir Douglas Galton as Chairman, a Reception Committee, with Sir Spencer Wells as Chairman, and Mr Malcolm Morris as Honorary Secretary, and a Finance Com-mittee, with Surgeon-General Cornish as Chairman, and Dr Moline as Secretary

There is also a numerous Indian Committee, with Mr. 5. Digby as Honorary Secretary, and an Eduing Committee.

Prof. Corfield, whose address at The mittee, with Mr S. Digby as Honorary Secretary, and an Edung Committee. Prof Corficld, whose address at The Haque Congress in 1884 was the origin of the present one (see NATURE, vol. xlim p 511) is the Honorary Foreign Secretary of the Congress, and 1r G V Poore the Honorary Secretary General

The Congress is divided into nine Sections under Hygiene, and one under Demography, which includes Industrial Hygiene, and deals with the life conditions of communities from statistical points of view. The Hygiene, Sections will meet in Burlington House and in the University of London They arc as follows -

(1) Preventive Medicine K C.S I. President, Sir Joseph Favrer,

K.C.S.I. (2) Bacternology Precedent, Ser Joseph Lister, Barr. (3) Bacternology Precedent, Ser Joseph Lister, Barr. (4) The Relations of the Desire of Chimala to those of March 1997 and the Chimala of the Chimala of the London School Board (5) Chemistry and Physics, in Relation to Hygiene Pre-

sident, Sir Henry Roscoe, M P

(6) Architecture in Relation to Hygiene. President, Sir Arthur W. Blomfield

(7) Engineering in Relation to Hygiene President, Sir John Coode, K C M G (8) Naval and Military Hygiene President, Lord Wantage,

(8) Naval and Military Hygiene President, Lord Walliage, K.C.B., V.C. (9) State Hygiene President, Lord Basing. The Demographic Division will meet in the theatre of the Royal School of Mines in Jermyn Street, under the presidency of Mr. Francis Galton

A large number of papers are promi ed, some on subjects selected by the officers of the Sections, and some on other subselected by the officers of the 'sections, and some on other sub-jects; indeed, there is such a profusion of papers that it seems very doubtful whether it will be possible to deal with them all during the four days available for the purpose, especially as we are liformed that most if not all of the Sections will only sit

are informed that most in man in the decomposition of the from 10 a m. to 2 p m. In the from 10 a m. to 2 p m. In A was number of public hocker in this country. Delegates have been appointed by the Gorenstein of all the European and several other countries, and all the years foreign Universities, cities, public inclusions, and all of years foreign Universities, cities, public inclusions, and all controllers. There are also a mamber of delegates from India and the colonies.

An Honorary Foreign Council, including the names of most of the best known foreign hygienists, has been appointed, and also an Honorary Council of the British Empire, with representatives from India and the colonies.

A Bacteriological Museum and Laboratory will be a special feature in connection with the work of the second Section; and an exhibition of drawings of sanitary construction, in connection with the work of the sixth Section, will be arranged in the Library of the University of London under the direction of Mr. Thomas W. Cutler.

As is usual in gatherings of this kind, a considerable number As is usual in gatherings of this kind, a considerable number of entertainments, excursions, &c., have been arranged for, including an entertainment at the Guidhall, conversationes at the Royal Colleges of Physicians and of Surgeons, and a dinner and file at the Crystal Palace.

A Ladies' Committee, under the presidency of Mrs. Priestley,

A Laber Committee, under the presidency of Mrs. Prietaley, has also been formed for the upropose of holding receptions and of organizing vivils to various places of interest for the lenders who may take this opportunity of visting London. He had to be the papers to be read, and the list of excursions, entertainments, e.c., for each day, and beades this, Public Health, the journal of the Society of Medical Officers of Health (under the editorial positions) of the society of Medical Officers of Health (under the editorial positions) of the society of Medical Officers of Health (under the editorial positions) of the society of Medical Officers of Health (under the editorial positions) of the society of Medical Officers of Health (under the editorial positions) of the society of Medical Officers of Health (under the editorial positions) of the society o

papers in each section A volume of abstracts of papers will also be issued, and a special hand book, for London is being prepared by Messry Cassell and Co in French and English, this will contain several maps and plans, and will be mainly devoted to those matters which have a special innerest for members of a

those matters which have a specific to the Congress of Hygiene and Demography
After the Congress a volume of Transactions will be published, to a copy of which each member will be entitled I subscription is \(\int \), and the offices are at 20 Hanover Square.

THE ORIGIN OF CERTAIN MARBLES!

A MONGST the interesting collection of rocks brought home by Prof Haddon from Torres Straits are some flagments of wind-hlown coral sand rock from Thursday Island have a deceptively colitic appearance, and the majority of the have a deceptively colutic appearance, and the majority of the grains being of a red colour give a prevailing warm tim to the grains being of a red colour give a prevailing warm tim to the dark green, worn, and rounded crystals of augite, which are scattered irregularly inrough it. The appearance of this hand-some rock is sufficiently siriking, but it gains greatly in interest from its suggestive re-emiliance to the fanous Tiree marble, from its suggestive re-emiliance to the fanous Tiree marble, wherein likewise green grains of pyroxene are set in a flesh-coloured matrix of altered limestone. The comparison is confirmed and enhanced by an examination of thin slices, in the recent limestone the calcareous grains are found, as so commonly happens with these coral-sand rocks, to consist of rounded fraghappens with those coral-sand rocks, to comsist of rounled frag-ments of calcareous Alga, and worn tests of various species of Foraminifera, mingled with these are more or last rounded crystal, not only of green august, but into of olivine, felspar, and a findy crystalline glassy basalt, in the Tirce marble the green at the control of the control of the control of the control of the sand of the control of the control of the control of the control they show no tendency to pass, crystals of felspar are also pre-sent—some faulty fiesh, other, and these are the manuty. they show no tendency to pass, crystals or tespar are ano pre-sent—some fauly fiesh, others, and these are the majority, corroded and almost entirely replaced by calcite, only the thin outer skin of the felypar preserving a fresh appearance; in some few case, fragments of felspar partially generated by salte are met with The calcareous matrix is finely granular, possibly dolomitic, but bloched and apotted by badly defined larger tousmitte, not noticed and spotted by budy denied larger crystalline individuals of calcite, the outlines of which are some-times obscurely rounded, so that although no trace of organic structure can now be recognized, yet on the whole the appearances structure can now be recognized, yet on ne whole one appearance are such as might be expected to be presented by a coral-sand rock, which had suffered metamorphic changes Macculloch, in his detailed account of this rock, refers to its occurrence as an analysis of the control of the control

and detailed account of this rock, refers to its occurrence as an arregular mass, completely surrounded by gness; another white limestone occurs in the island, similarly disposed. It is interesting to speculate on the final result of pressure metamorphism, acting on volcanic uslands surrounded by their reefs. Thus, were the ancient granter masses of Queensland and New Guinea to approach one another, moving towards the line

A Suggestion by Profs Sollas and Cole

NO. 1135, VOL. 44]

of weakness which now forms Torres Straits, we may conceive of weakness which now horms forme Stratis, we may conceive that basic schules in great variety would arise from the rolling out of the cores and superficial deposits of the intervening volumes, while the associated coral reefs would be converted into tregular masses of structureless limestone, and becoming movied in the surrounding sentiats would be irregularly dispersed through them, so as to occur in unexpected and anomalous

positions. In conclusion we would call attention to an important paper, read in 1876, by Mr. W. I. Green, Minister of Foreign Affairs to the King of the Sandwich Islands (footnote, Journ. Roy. Geol Soc. Ireland, vol. iv. p. 140, 1877). Inter alia, he

says —
"The Hawaiian Islands are more or less surrounded by coral reefs. the island of Hawaii less so than the other, for one reason, reets, the maint of riswan ress so that the outer, not one specially the laws has kept pouring into the sea along most parts of the coast during past eenturies, and has not given the coral an opportunity to form to so large an extent as in the other islands. Now it is a fact that wherever the lava runs into the sea, or

Now it is a fact that wherever the lava runs into the sea, or wherever the waves have an opportunity of breaking against [ii], a large quantity of olivine sand is formed. The felipar, the other material of which this lava is mainly composed, gets ground up to powder and disappears—indeed, it is almost always in the content of the cont in the minutest grains to begin with, whilst the olivine, a much heavier mineral, and in grains from the size of a hean to a pea downwards, forms the main component of the sand of the sea-shore wherever the sea meets the lava, or else the olivine-sand gets more or less mixed up with the coral-sand, where the two classes of tock are in close proximity. A great deal of the olivine-sand is of the finest possible quality, indeed, it is often so fine that although a much beavier mineral than carbonate of lime, it will often, where both are washed by the waves, settle on the top of the coral sand, and I have often scraped the almost pure fine olivine sand from the top of a cornl sand beach mixture of the two sands is common over the group, extending 400 miles from Hawaii to Bird Island "Again, "there severy grade of mixture from all coral to all olivine Very often the olivine sand rock will be found to run in streaks amongst the coral sand rock, so that in the course of time, when the coral sand rock comes to be metamorphosed into a limestone or a marble, the olivine sand rock would probably suffer the change which that mineral is well known to experience—namely. into sernentine

These views will certainly commend themselves to many of hose who have come to regard Lozoon as a mineral structure With the presumption in its calcareous composition of an organic origin, there has always existed a suspicion that some such ex-planation as this might eventually be found. It is interesting to note that the streakiness which Mr. Green expressly mentions as characterizing the interlainment of the olivine and coral sand, is so frequently an accompaniment of "Eozoonal" and serpentinous limestone

IS THE MARINER'S COMPASS A CHINESE

A WRITER in the North China Herald of Shanghai devotes a learned article to detailing and discussing the facts regarding the claim of the Chinese to have invented the mariner's compass They did not learn the properties of the magnetized needle from any other country. They found it out for themselves, though it is impossible to point to the man by name who first observed that a magnetized needle points north and south. He suggests that it came about in this way. The Chinese have in their country boundless tracts of ironstone, and among these no small portion is magnetic. Every woman needs n needle, and iron early took the place of the old stone needles, and were commonly used before the time of Ch'in Shih-huang—that is, commonly used to enter the time of Chin Shurahang—ind a, more than twenty-one centuries ago. Whenever a needle hap-pened to be made of magnetic iron, it might reveal its quality by falling into a cup of water, when it happened to be attached to a splinter of wood, for example It came in some such way to a splinter of wood, for example It came in some sach way to be known commonly that certain needles had this quality. The great producing centre for magnetic iron in Tsachou, in Southern Chihit. That city was very early called the City of Mercy, and the magnetic stone produced there came to be known as the stone of Tsachou, and so Tsachou, and so Tsachou, the conditions are for a magnet Later, the Chip the City as the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted of calling in the "City of the Magnet," mitted the calling the mitted of calling in the "City of the Magnet," mitted the calling the calling the mitted that the calling the ca Mercy." The polarity of the magnetic needle would become known to the Chinece of that city and its neighbourhood first. The first who noticed the polarity would be some intelligent person who communicated the fact as an unaccountable penaltarity in an age when omens and portents were diligently sought for in every natural object and phenomenon.

seught for in every natural object and phenometon.

The earliest author who mentions the "isouth-pointing needle" lived in the fourth century is a There can be so that the property of the control of th

Royal Society, July 2007. The Market Lird McLaren, Vice Prevident, in the clair—Mr. John Auther need a page on the solid and liquid particles in clouds (see p. 279, July 23).—Prof Tatt communicated a pager by Prof Chrysial on a demonstration of Lagrange's rule for the solution of the linear partial differential equation, with some historical remarks on defective demonstraons hitherto current Prof Chrystal's proof is purely analytical Prof Tait remarked that, on quaternionic principles, the problem may be regarded as follows. Let the equation be

Pp + Qq = R

where P, Q, and R, are given functions of x, ν , and z, and p, q, represent respectively the quantities dz/dx, dz/dy. By the in troduction of a new variable, u, this may be put into the form

$$P\frac{du}{dx} + Q\frac{du}{dy} + R\frac{du}{ds} = 0.$$

But du/dx, du/dy, du/ds, are proportional to the direction cosines of the normal to the surface u=c, and therefore P, Q, R are proportional to the direction cosines of a tangent line to Hence we deduce, as the equations of a curve which hes wholly on the surface.

$$\frac{dy}{dt} = \frac{dy}{dt} = \frac{dz}{R}$$

The integrals of these equations are known to have the form v = a, $w = \beta$, where a and β are arbitrary constants. The intersections of these surfaces fill space with a set of lines, and the problem is to find a single general set of surfaces upon which the proofem is to find a single general set of surfaces upon written these lines will lie. Their equation is v = f(v), where f is an interest of the surface of the sur secordance with the direct observations of Drs. Ramsay and Voung. THURSDAY, AUGUST 6, 1891.

A PHYSICIST ON COLOUR-VISION.

Colour-Measurement and Mixture By Captain Abney (London. The Society for the Promotion of Christian Knowledge, 1891)

HIS interesting little book extends over only 200 pages, but is full of careful and important observa-It is, in fact, a summary of the results arrived at by the author during his careful and laborious investigation of the properties of the spectrum. It forms one of the "Romance of Science" series published by the SPCK., a series intended " to show that science has for the masses as great an interest as, and more edification than, the romances of the day" Now, though the earlier portion of this book could be understood by anyone, we venture to think that the second half is for the most part so technical that the full meaning and value could only be appreciated by those who are more or less conversant with the methods of experimenting on colour. To those who are familiar to even a slight extent with the technicalities of colour experiments, the characteristic of the book is its extreme lucidity. We are carried on from point to point, until, when we look back on the closed book, we find we have travelled over the greater number of the problems of colour-vision almost without effort. It is a book which will not appeal to the masses, but should be read by every physiologist and physicist interested in

There is yet another reason for the interest which attaches to this work, necessitating a faller notice than if it were simply a popular disguisition on colour. It is the record of a careful series of experiments by an eminent physicist, firmly convinced of the truth of the Young-Helmholtz theory of colour vision. The voluminous work of Hering and his pupils is not once mentioned through-out the whole book, although Kong's later publications receive due notice. In fact, if space permitted, we cannot imagine a book more calculated to form the basis of a fruitful discussion on the ments of the rival theories than that now before us. For both the problems of colourvision, and their solution according to the Young-Helmholtz theory, are definitely and clearly stated.

The book opens with a description of the methods used to obtain a spectrum, and a consideration of its properties with especial reference to the ultra-red and ultra-violet rays. The apparatus used by the author to investigate the three fundamental properties of colour—hue, lummosity, and purity—are described in detail. Absorption and interference are then touched upon in their relation to colour, and experiments are given to show that the colour of a body is due to its refusal to transmit or reflect certain rays of the spectrum. This is followed by an interesting chapter on scattered light, with especial reference to atmospheric effects, and a pretty lecture-room experiment is described to show that the change in the colour of the sun when on the horizon is produced by small particles in the air.

The author then passes on to consider the second property of colour—luminosity; and the luminosity of the apectral colours is measured as follows. The light from a

certain portion of the spectrum passes through a slit which cuts off the remainder of the spectrum. A portion of the same white beam which was decomposed by the prisms is reflected on to the same screen as the monochromatic beam, and an upright rod is interposed. This rod throws two shadows, whose intensity is compared after the manner of a photometer The luminosity of the whole reflected beam is greater than that of the coloured beam, and a rotating diaphragm, with variable sectors, is therefore interposed in its course. By altering the size of the sectors, the intensity of the white light is diminished, until the luminosity of the shadow it casts is equal to that cast by the monochromatic beam. The luminosity is then read off in terms of the segment of the circular diaphragm which remains open when the luminosity of the two shadows is equalized. The luminosity of all the principal points in the spectrum is measured on this plan Subsequently the luminosity of a combination of red and green is shown to be could to the sum of the luminosities of the saine red and green determined Three colours, A, B, and C, are chosen, separately which, when combined, make white of a certain intensity, W; and the author shows that if the luminosity of the combined light A + B be subtracted from the luminosity of the white light. W. the remainder exactly equals the luminosity of the third factor, C

A curve of luminosity can be constructed in this manner for the whole spectrum, and its maximum is found to he on the yellow side of the D line. A similar luminosity curve is given for an observer who was what is ordinarily called red-blind. On this curve the red end of the spectrum is shottened, and the maximum luminosity falls nearer the green than on the curve constructed for a person with normal colour-vision. These facts are capitated as follows. To the red-blind observer red is invisible, and therefore the luminosity of red is abolished; the luminosity of yellow, which is composed of red and green, is also duminished, and thus the maximum of the curve moves towards the green.

This question of luminosity is intimately associated with the theory of the value of white in the system of colour. The author discusses later on in the book the abolition of colour by white light, and examines the extent to which white light can be added to a colour without being perceived. He finds that both depend on the luminosity of the colour, and formulates the law that "the extinction of every colour is effected by white light that is 75 times brighter than the colour." Again, he finds that a large proportion of white light can be mixed with yellow without being perceived, whilst a very small proportion of white added to blue is at once apparent

An attempt is made to explain these facts on the Young-Helmbott theory; but the work done by Hillebrand! under Henng's gudance, makes the explanation offered very improbable. Hillebrand used an apparatus in which one half of the field could be illuminated by a monochromatic spectral colour, whilst the other half was illuminated by white light. The observer shelded one eye from the light for a considerable time, so that it was ultimately brought into a condition of complete rest. Now if he looked at a field field with monochromatic

^{4 &}quot;Ueber der specifische Helligkeit der Farben," Seleb d h Akad d Wissenschaff, in Ween, February 1889

light of moderate intensity with the rested eye, it appeared to him colourless; and by suitable adjustment he could make an absolute match between the half of the field illuminated by monochromatic light and the other half illuminated by white light from the same source. Thus, as the whole spectrum appeared colourless, he was able to construct a curve of luminosity for the spectrum by matching it with the white light in the other half of the field. The maximum of this curve lay in the green A glance with the unshaded eve at once brought the colour into view, although the field was unaltered. But as soon as the colour came into view, he noticed that the luminosity of the coloured half no longer matched that of the colourless half of the field If yellow or red were the colour chosen, the luminosity of the coloured half of the field appeared to exceed that of the colourless half, whilst if green or blue were selected the exact opposite was observed. Moreover, as soon as the colours of the spectrum were appreciated, the maximum luminosity shifted into the vellow, and the curve he then obtained closely resembled that constructed by Captain Abney and other observers. Thus we must conclude that every part of the spectrum is capable of exciting the sensation of white apart from its specific colour, and that the maximum sensation is produced by a certain point in the green As soon, however, as the colour becomes apparent, this sensation of white is either increased or decreased by the specific luminosity of the colour The luminosity of the spectrum, as determined by Captain Abney, is the algebraic sum of two factors. Firstly, the power which every part of the spectrum possesses of exciting the sensation of white; and secondly, the specific luminosity of the colour sensation itself, which is a positive quantity on the red and yellow side and a negative quantity in the blue

If this explanation for the difference in the two curves be correct, a person who was completely deficient in colour-sense would construct a luminosity curve for the spectrum differing considerably in the position of its maximum from that given by Captain Abney in his book. The curve obtained by Konig I from a man to whom vellow, blue, green, and red were invisible, to whom the whole spectrum appeared in varying shades of white. shows that this is the case The maximum luminosity lies in the green, over the line b A comparison of this curve with that given by Hillebrand for the normal eye at rest reveals their almost absolute identity. The existence of this form of colour blindness can only be explained with extreme difficulty on the Young-Helmholtz theory; whereas Hering's hypothesis, that white and black form a colour pair analogous to red and green, yellow and blue. not only renders the existence of such a condition probable, but also easily explains Hillebrand's results.

The author passes on to show that white can be produced from the mixture of three spectral colours, and ultimately defines a primary colour as one which cannot be formed by the mixture of any other colours. The three primary colours he selects are red, green, and

violet; for yellow is formed by a mixture of red and orgene, blue by a mixture of green and violet. But he he warms us from assuming that the three primary colours warms us from assuming that the three primary colours (p. 138). On p. 150, or red (between C and the lithtum line), violet (close to G), are selected as furnishing two primary sensations, whist "all three fundamental sensations" are excited by the end of the primary sensation was the way of the primary sensation will be settled by the way of the primary sensation was the primary sensation where the green is mixed with

Now, to say that ap-ctral green excites the sensations of red and voice seems to us radically faise. For when speaking of sensations we leave the realm of physics, and the sole test of the sensations sectied by a portion of the spectrum is the colour which we perceive when light from that part impages on the retina. No one who examines spectral green will say that it gives him the sensation of erd or voice, but rather that the greater part of spectral green appears to be mixed with either yellow or blue. Again, a primary sensation must be one which gives us the sensation of one colour only. Now every eye sees in voice both blue and red. Thus, whether voice be a primary colour from the physical point of view, physiologically speaking it is anything but a primary sensation.

Though violet fails to answer the test of a primary in colour sensation, a point can be found both in the yellow and the blue of the spectrum, from which the sensation of one colour only is obtained. But throughout the book we find repeated mention of the formation of yellow by the mixture of spectral red and spectral green. How can this be reconciled with the acceptance of yellow as a numary sensation?

To most eyes, the red of the spectrum yields to a greater or less extent the secondary sensation of yellow. Take such a red, and gradually add minute quantities of spectral blue The yellow will gradually disappear, and a red will be produced, which yields the sensation of red only, untinged with either vellow or blue. Take a spectral green, which is also slightly yellow, and treat it in the same way. If we now mix the absolutely pure red with the absolutely pure green, white is produced, not vellow And now we can understand why spectral red and spectral green can be made to form yellow For both the red and the green, which, when mixed, form yellow, when separate give the secondary sensation of vellow in addition to that of their principal colour Thus, when mixed, the pure red annihilates the pure green, and yellow only remains. Measured by this standard, the primary colour sensations fall into two groups, in which each colour is complementary to the other Firstly, red and green, from which all secondary sensations of yellow and blue are absent, and secondly, yellow and blue, which do not give the secondary sensations of either red or green

Colour-bindness is brought in to support the Youngclimboit theory, but the author has obvoouly not had the opportunity of investigating many cases of this affection. He speaks of green-blindness, in which the sensations of red and violet are present, but not that of green, and of red-blindness, in which the sensations of green and violet are present, but not that of red; and gives measurements to show that in the latter class of cases the spectrum is shortened.

Die Grundempfindungen u ihre Intensitäts-Verbistung im Spectrum," Stith d k preuz Ahad d Wissenskhaft in Resin, zuzik, 1888 Hering has under shown, by investigating a similar case of total colour-bladonst, how closely the curve of humnosity agrees with that green by Hildbrand I be account of this interesting case has not yet beer

Now. Hering 1 has particularly investigated this portion of the subject, and explains the existence of two forms of colour-blindness as follows. He finds that persons with a normal colour-vision can be divided into two groups The one class perceive yellow, the other blue, with exceptional ease, probably owing to a difference in the pig-The difference mentation of the media of the eye between the two groups is best seen with spectral green; for a green can be found which appears at the same time yellow-green to the one, blue-green to the other To an observer with strong yellow vision, almost the whole of spectral red appears to be tinged with yellow, whilst a member of the second group, whose strong sense of blue prevents his seeing the yellow, pronounces the greater part to be pure red. Thus, the pure red and the pure blue are radically different colours for the two groups. Now, it is found that the pure red and the pure green formed for an observer with a strong sense of yellow appear grey to one who is what is called green-blind . whilst, on the other hand, the pure red or the pure green of the observer with a strong blue sense appears colourless to one who is red-blind A red which is invisible to one who is "red-blind" is evidently coloured to a patient who is green blind, and he speaks of the colour he sees as red But if a minute proportion of blue is added, the red gradually becomes purer until it becomes free from vellow to those of us who have a strong yellow sense As the red becomes purer, our green-blind patient complains that the "red" is fading, and when finally the red is quite pure he matches the colour he sees with a grey, and says that the colour has gone Thus, there is no fundamental difference between the red- and the greenblind Neither group can perceive red or green only difference between them is one which we find amongst normal-sighted persons-namely, a different visual acuity for yellow and blue The "red" of the green-blind is in reality the secondary sensation of yellow yielded by almost all the reds in nature, differing from the ordinary yellow in its limited power of exciting white This peculiar yellow he has learnt to associate with what others around him call red, and he only betrays his affliction when all yellow is climinated from the colour he calls red Thus, a consideration of colour-blindness again leads us to throw red and green, blue and yellow, together into two groups as primary colour sensations

Simultaneous contrast is touched on very superficially, and successive contrast is scarely mentioned, yet the author again grasps at the three-colour theory to explain the few phenomena he mentions. Yet it is notorious that the Young-Helmholtz theory fails to afford any adequate explanation of the phenomena of contrast. It was by an ingenious contrast experiment that Hering produced such a striking confirmation of his views before the Physiological Congress at Basle, and placed the three-colour theory in a dilemma from which its ablest exponents have not yet succeeded in extracting.

In conclusion, the book before us is an admirable summary of a valuable series of experiments. We can scarcely imagine that it will appeal to the public in

general But it should be read by those who are interested in the phenomenon of colour-vision, and the fact that the author frankly accepts the three colour theory and ignores the work of Hering does not, in our opinion, detract from its value. For the book thus becomes an admrable statement of the strongest portion of the physical theory of colour by one of the ablest of English hysticitis

POSITIVE SCIENCE AND THE SPHINX

Riddles of the Sphinx A Study in the Philosophy of Evolution By a Troglodyte. (London, Swan Sonnenschein, 1891)

THESE be old old nddles that the Sphinx propounds I and the Tropledye attempts to guess, in the volume before us, none other, indeed, than the What, Whence, and Whither of man and of the world There have been other guesses in the past, there will be other guesses while time last, each guesser thinks his own guess nearer the true answer than any other, his neighbours mostly sinke, unless his guess chances to be something like their own, and the Sphinx looks on with stony stare, imperturbable, giving no hints.

So soon as man, as man, looked out upon the world, and began dimly to realize the first personal pronoun, the nascent reason, or, if the phrase be preferred, intellectual faculty, demanded, for the first time in the history of the development of consciousness, an explanation Man, then as now the chief centre of interest to man must thenceforward not only live and act, but must seek to explain his life, and his activity Yesterday the tribechief went forth a living man, feared by all . to-day his body is brought back, helpless, lifeless, and a hog spurns it with his shout How account for this? How explain this change? Something there was about the man vesterday which made him totally different from the mere mass of clay that to-day already needs hustling out of sight That something, call it soul, spirit, energy, life, what you will, has departed Whither has it gone?

This question, eminently natural, almost inevitable, opened the way for reason's first blunder to enter and to become a fruitful mother of children. Reason, in the exercise of the new-born analytic faculty, distinguished between the mere body and the informing something through which it was a living body, between the material substance and the spirit-energy which was associated with that substance during life. But reason also jumped to the conclusion that what were distinguishable in thought were also capable of separate existence in fact The matter remains in the corpse, but the something, the spirit-energy, has escaped, to lead a distinct and independent existence. In justification of this conclusion the phenomena of dreams were no doubt adduced as evidence. While the chief's body was lying stark and stiff, his true self, his spirit-energy, appeared by night to more than one of his chosen followers Thus the dream seemed to support the false conclusion of the nascent reason, which had not yet learnt to distinguish without dividing.

It has cost positive science much labour, and not a few hard blows, to establish, by detailed work in physical science, biology, neurology, and psychology, the ille-

[&]quot;Zur Erklörung d Ferbenblindheit" (Prag. 1880), "Ueber Individualle Vorschiedenbeiten des Farbenannes" (Prag. 1880) Ergebruchten Vorschung z. dagnose d Farbenblandheit, "Ueber d. Erklörung d. periphären Farbenblindheit," "Enseinige Storungen d. Farbenauenes," Arktir f. Orkhälmeiter, axxiv

gitimacy of this conclusion. Now we distinguish further. but no longer divide. We distinguish between the material substance of the body and the energy of molecular motion during life; and, further, between the molecular motion of the grey matter of the cerebral hemispheres and the concomitant manifestation of consciousness. But although consciousness is distinguishable from molecular energy (and the distinction is absolute), it is not, so far as positive science can say, divisible therefrom. No physicist holds that the special modes of energy-we iftean the particular groupings and interactions of energy -which characterize the functioning of a man's brain, escape from the molecules at death, and henceforward persist divorced from matter. We cannot, however, add that no psychologist holds an analogous doctrine concerning consciousness But we contend that no psychologist is justified on positive grounds in holding such a view That something called soul or spirit escapes from a man's body at death, and henceforward persists, divorced alike from matter and energy, is a view to which positive science as such gives no support. It is held by those who hold it on quite other grounds. The conclusion to which positive science points (and we include among positive sciences psychology, which deals with consciousness as existent) is that consciousness, though distinguishable from energy, is known only in association with certain forms of energy in organic tissues

But this is a conclasion which is ignored by the Troglodyte. He professes to give us a "philosophy of evolution" which he himself describes as "the first perhaps which accepts without reserve the data of modern science." His theory of a Transcendental Ego, his suggestion that "matter is an admirably calculated machinery for regulating, limiting, and restraining the consciousness which it encaces", his conception of a graduated unmortulity, from that of an aniocha up to that of man, his attempted rehabilitation of the view that force-atoms are monads "endowed with something like intelligence, and thus enabled to keep their positions with respect to one another", all this, and much besides, seems to us completely off the lines of modern scientific davance

But it may be said that such conceptions, though unnecessary for positive science, may be nocessary for a philosophy which endeavous to go beyond and get behind science. In reply to this we can only say that we regard such conceptions as not only unnecessary to the positive science, but unwarrantable intrusions into her domain. They form part of a different scheme of thought. The muddling together of positive and metaphysical conceptions is provocative of nothing but confusion and had temper.

The introductory chapters of his first book, in which he author attempts to hound on positive science from agnosticism, through universal scepticism, to a gloomy pessimams, seem to us laboured and inconclusive, though there are incidental positions here and elsewhere with which we arean complete accord. With dogmatic Agnosticism and the Cult of the Unknowable (capital letters indispensable) we have but little sympathy. But this is no necessary part of the attitude of positive science, which seems to us briefly as follows in the first place its followers take their start from the measurable and verifiable base-line of perceptical expensione, from the ordinary

facts of daily observation: and they utterly refuse, at this stage of the inquiry, to listen to the metaphysicians who hoot from their cloud-land, "But you haven't vet proved the existence of matter, or explained how it is possible to perceive or know anything at all," Starting, then, from the base-line of perceptual experience, they analyze phenomena, digging down by wise abstraction and the ignoring of unessentials, to deeper and deeper concepts, until they arrive at those universal abstracts which cannot be got rid of in thought without reaching nonentity. Happy they who in this procedure escape the analyst's fallacy-the supposition that the results of abstraction have a fuller reality than the phenomena with which they started The analyst needs often to be reminded that the perceptual rose, with its delicate scent, its rich colour, its soft petals, is certainly not less real than the vibrating molecules which remain to his thought when, as physicist, he has stripped it of all its own peculiar charms.

Thus positive science in its deepest analysis brings us down to matter, and energy, and consciousness. If a number of metaphysical questions are intruded at all sorts of stages during this process, the result will be such confusion as the Troglodyte unconsciously exemplifies in his chapter on scepticism, a chapter in which some stress is laid on, and some capital made out of, the false psychological conclusion that conceptions cannot be derived from experience. Should the author ever come to grasp that the law of psychogenesis is one and indivisible, and sweeps through perceptual and conceptual processes alike, he will have to rewrite much of the "Riddles of the Sphinx" But, as he himself tells us, "the minds of most men are fortresses impenetrable to the most obvious fact, unless it can open up a correspondence with some of the prejudices within "

When positive science has dug down to basal conceptions, then, and not till then, in logical order (but, of course, far earlier in historical order) arises the question, "But how does it all come about? What is the origin and meaning of it?" We quite agree with the Troglodyte that this question must arise in the mind of every man in so far as he is a thinking man. The question, "How does it all come about?" however, presents two faces It may mean, "How can we explain the fact of knowing?" And the solution of this problem is, we agree with Mr Shadworth Hodgson in maintaining, the true business of philosophy But even supposing that philosophy explains in some sense the process of knowing, there still remains the question in its further aspect, "But how does it all come about?" To this question, positive science as such answers, or should answer, humbly, and with no parade of capital letters, "I do not know"

And is that the end of the matter? So far as positive science at present goes, Yes But man, the questioner, still remains, and Reason, true to her first impulse, still demands an explanation. Of the explanation afforded by revelation this is not the place to speak. But, quite apart from the fact of revelation, the explanation said to be revealed still stands as a product of the human mind. And he is a bold man, if not a foolish, who, having regard to the past history of human thought on the question, lightly sets aside the conception of a Caussa causturem to whom we may attribute "problectally all the higher attributes of man; not because personality, wisdom, love (the symbols we employ), can truly describe or define that which passes man's comprehension, but because being man we can no other. Man alone in the organic world is capable of ideals, and for generations the name of God has stood for man's central ideal of power and perfection And it seems to us that the sum and substance of positive criticism as applied to man's conceptions of that which admittedly lies beyond the reach of positive science comes to this. "You must frankly acknowledge and confess that such conceptions are symbolic and ideal." But if symbolic and ideal we must expect the symbolism to be variable in different ages, among different peoples, and even in different individuals. Hence (apart from revelation) the only indefensible attitude is that of inelastic dogmatism, positive or negative

In conclusion, we may say that the "Riddles of the Sphint" are in this work treated with considerable, though frequently misquided, power. The conception of evolution as a tendency towards an ideal of perfect individuals in a perfect society is good, and is in parts well worked out. That many will be found to acquiesce in the author's solutions of the old problems of hie we think exceedingly doubful. Not do we think that the solutions will prove of lasting value. It is futile to attempt to preserve the new wine of positive science in the old bottles of presistentic metaphysics. Fin new wine must be preserved in new bottles. In other words, a new interlapies insust be and is being elaborated, in special relation to the newer aspects of scientific thought.

ANALYTICAL METHODS OF AGRICULTURAL CHEMISTS

Proceedings of the Association of Official Agricultural Chemists, 1890 (Washington United States Department of Agriculture)

THIS is a Report of the Seventh Annual Convention of the Association, under the Presidentship of Mr M A Scovell, and with M1 H W Wiley as Secretary The objects of the Association are to secure uniformity and accuracy of methods, results, and modes of statements of analyses of manures, soils, cattle foods, dairy products, and other materials connected with agricultural industry, and to afford opportunity for the discussion of matters of interest to agricultural chemists. In the words of a past President, it aims at laying "a foundation so solid, that every Court in this land must respect its conclusions, and every analytical chemist, whether he lives in this country of elsewhere, must be forced either to practice or admit the advantages and correctness of our system of analyses" A study of the programme and of the proceedings shows that the objects have been most carefully and conscientiously kept in view, and that all the working members have been most thoroughly imbued with the spirit of the Association

The reports submitted for the consideration of the meetings, all drawn up by experts, and incorporating the work of many members, were as follows: on the determination of nitrogen; on analysis of dairy products; on analysis of potash; on analysis of cattle foods; on analysis of

sugar; on analysis of phosphoric acid; on analysis of fermented liquors, and a report of a Committee on foods and freding-stuffs

As an example, for the report on the determination of nitrogen in manures, three samples, containing nitrogen in different states of combination, were prepared, and sent to the members for analysis by various official methods. Twenty-two reported the results obtained by Kieldahl's method on one sample, the same number the results of Kieldahl's method modified for nitrates on two samples, and a less number gave results by the Ruffle method, the soda-hme method, and Dumas's method on one or more of the samples The whole of the results are collated, with the remarks of the analysts thereon. so that data are obtained for testing the accuracy of the methods under various conditions, and climinating personal factors Various suggestions for the improvement or simplification of the processes are made and discussed, and some of them recommended for systematic trial during next year Similar good work is done for the other Committees

The remarks of the Committee on ways and means for securing more thorough chemical study of foods and feeding-stuffs, are particularly worthy of attention, pointing out, as they do, the deficiencies in present methods of analysis, and the absolute necessity of more exact methods and more accurate study of the proximate principles contained in foods, and of their physiological value. As a contribution towards this knowledge. Mr W L Stone sends a paper on the occurrences and estimation of the pentaglucoses in feeding-stuffs, in which he shows that bodies yielding furfurol, and therefore presumably pentaglucoses, are present in grass, straw, linseed meal, and a great many other feeding-stuffs Among the points which are noticed, and which should be known to all analysts, is the fict that cotton-seed meal, often used in mixed manures in the Southern States, is completely soluble in nitric acid with a little hydrochloric acid, but that the solution does not yield all its phosphoric acid to aminonium molybdate.

Should such a Itill as that introduced by Mr. Channing, for the better prevention of the adulteration of inanires and feeding-stuffs in this country, ever become law—and the Government has promised to take up the matter—the formation of such an Association of Official Agricultural and Analytical Chemists in this country would be almost a necessity, and it is seems that the Institute of Chemistry is the proper body to arrange the organization of such an Association.

GEOLOGICAL RAMBLES ROUND ABOUT LONDON

Hand-book of the London Geological Field Class By Prof. H. G. Seeley, F.R S. (London. G Philip and Son, 1891.)

THIS little book is a record of excursions similar in some respects to those collected in the volume of Geological Excursions which was noticed in these columns on June 18 (p. 149). But there are points of difference. This hand-book deals with a more limited area, being practically restricted to the south-east of England; it has purpose more definitely cloudational. The la'ere may

be described in a few sentences extracted from the preface -

"This Society exists to teach the elements of Physical liminary study from books . . The field work has been led up to by short courses of winter lectures given in London, designed to connect together the observations to be made in the succeeding summer, and to connect the geology of the district to be examined with that of other areas

The excursions are described in the notes written by atudents in the field; the lectures are reported (from shorthand notes) by Mr. White, one of the class. As regards the former, Prof Seeley states that "students have been free to report what they saw and what they heard, and they have severally written in their own ways both as to length and language used." The lectures also "were not constructed with a view to being reported, nor were the reports written out with a view to being printed." Prof. Seeley has, however, " read the proof to remove serious inaccuracies" The lectures need no apology, for they are excellent examples of that clear and suggestive method of teaching of which Prof. Seeley is a master The reports of the excursions also acquire a certain freshness as recording the impressions of novices, and may on that account be even more helpful to beginners than if they had been written by more experienced observers. One or two maccuracies, however, appear to have escaped the Professor's watchful eye Is not the statement on p. 18, relating to the presence of Paludina and Unio in such Wealden Limestones as the Petworth Marble, a little misleading? for it implies that the latter genus is common in these deposits, which, we believe, is not the case. A sentence on p 20 suggests that "enormous pressure" is requisite to convert a sandstone into a quartzite. Very probably this would be the result, but there are not a few quartzites which show no signs of having been specially subjected to pressure. Also, it is hardly correct to call Lydian stone an altered sandstone. Again, more than once it is intimated that gness and crystalline schists occur in Belgium. This, if the terms be used in their ordinary sense, is incorrect; and even the perphyroids and amphibolites, and the abnormal rocks of the Bastogne district, the vague descriptions of which may have given rise to this misconception, are of extremely limited extent But these are very trifling blemishes, which can be readily removed in a second edition. The book will be of great use to all students. living in or about London, in helping them to use their eyes, and most of all because, to quote Prof. Seeley's words, "It here and there touches upon problems which are not usually presented to beginners." But, as he rightly urges, these problems-namely, the application of stratigraphy to the elucidation of the physical geology of past epochs "should never be absent from the mind of anyone who considers geological facts in the field " T. G B.

OUR BOOK SHELF

Katalog der Bibliothek der Deutschen Seewarte zu

NO. 1136, VOL. 44]

Hamburg, describing the building, its equipment of instruments, and the important work which is carried on there chiefly in the interests of the German Imperial and mercantile navies

As this institution is possessed of a library containing some 10,660 works, it has for some time past been a matter of urgent necessity that an accurate and wellpublished The required book was completed last year. and is now available.

This Catalogue shows that the library contains a large proportion of works either directly of a naval character or bearing upon naval matters, whilst several other branches of science are fairly represented.

As might be expected, meteorology holds the first place of importance, and amongst the 2760 works on this subject are a large proportion of Dove's writings. Indeed, it seems worthy of note that Dove's library, which occupied him many years in collecting, may now be found at the German Naval Observatory Turning to the division of the Catalogue on physics, 1617 works will be found; on magnetism and electricity, 974, whilst other subjects, such as navigation, hydrography, and construction of ships are well cared for

Although the books and papers mentioned in this Catalogue are generally printed in the language adopted by their authors, a translation into German of several works of interest is also placed side by side with the original

In conclusion it may be remarked that although there is nothing specially new in the arrangement of this book. it is well worthy of the time and energy which have evidently been spent in bringing the work to its present

Scientific Results of the Second Yarkand Mission, based when the Collections and Notes of the late Ferdinand Staticzels, 1th D—Coleoptera By H W. Bates, F.R.S. J Baseon, and F. Bates. Pp. 1-79 and 2 Plates (Calcutta: Published by order of the Government of India, 1850)

THIS, the twelfth part issued, all but one of which deal arms, me wentin part issued, all but one of which deal with zoology, contains an enumeration of 207 species of Coleoptera. These species belong to the following families: -Cicindelider (4), Carabidae (60), Longicomia (5), Phytophaga (25), Halpidae (1), Dytiscide (8), Gynnide (1), Hydrophilder (3), Staphylinidae (9), Scarabidae (38), Staphylinidae (38), Scarabidae (38), Staphylinidae (38), Scarabidae (38), Staphylinidae (38), Scarabidae (38), Staphylinidae (38), Scarabidae (38) bæidæ (38), Cetoniidæ (3), and Heteromera (50). Diagnoses or descriptions of all the new genera and species were published more than ten years ago, and the only additional information contained in this part is a list of species, in addition to, in some cases, fuller descriptions of the novelties. In the portions contributed by Mr H W Bates and Dr. Baly, both of whom, however, give some particulars regarding geo-graphical distribution, the references to the published diagnoses are given; but in Dr Sharp's and Mr. F. Bates's contributions, many of the genera and species are mentioned as new, though diagnoses of the whole of them of the Asiatic Society of Bengal, xivit Part 2 (1878), the latter in Cistula Entomologica, 11, (February 1879). The two plates include 44 figures - Carabidæ (17), Longicorma (5), and Heteromera (22) On the cover, and also on p. 37, the name "Hydrophilide" is misprinted "Hydro-ptilide" The Hydrophilide do not belong to the order Coleoptera at all, but to the Neuroptera! It is to be regretted that a delay, the cause of which is not ex-plained, of more than ten years, has occurred in the publication of the "Part" dealing with the Coleoptera, as Katatog der Bibioteks der Duttschen Seemerte zu Hamburg, (Hamburg, 1890) – Hamburg, 1800 – Ha NATURE

yet been published, and even a fragment like the present, containing a his of the species of a neighbouring reason, is a welcome addition to our knowledge. Four other "Parts" have been issued on the Insecta-the "Neuro-ptera" and "Hymenoptera" (both in 1878), and the "Lepidoptera" and "Rhynchota" (both in 1879), the last Part of the whole series being the "Araneidea" (1880).

Popular Astronomy By Sir George B Airy, K C B Seventh Edition. Revised by H H Turner, M A, B Sc (London Macmillan and Co, 1891)

ALTHOUGH our astronomical knowledge has been enormously extended since the lectures forming the basis of this well-known book were delivered (1848), Mr. Turner has not found it necessary to make any very considerable revision, for the reason that the advances have been chiefly on the chemical and physical sides Still, in the lapse of time, methods of observation have been unproved, and accounts of these find a place in Mr Turner's notes. Among these are short descriptions of the chronograph and the new "electrical controls" for the drivingclocks of equatorials One of the most noteworthy points brought out in the new edition, however, is the modern estimate of the value of observations of the transit of Venus as a means of determining the solar parallax. It was formerly supposed that this would be one of the best methods, but the difficulties encountered in 1874 and 1882 prevented observations of the necessary degree of accuracy; and now most astronomers are of opinion that this method can never give more than an approximation to the truth. Numerous minor additions have also been judiciously made

LETTERS TO THE EDITOR

[The Editor dost not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to convespond with the worster of, rejected manuscripts intended for this or any other part of NATURE No notice is taken of anonymous communications.

Force and Determinism

"THE relation between force, which is a mechanical thing, and will or life, or whatever it is, which is a psychological thing"—a relation which, as Dr Lodge rightly says, "demands investigation"—presents itself to some of us as follows

When a stimulus received by an organism gives rise to a response, however particular to the inhividual respondent, there are (1) a number of complex but determinate molecular changes in the organic issues, and (3), accompanying once of these changes, orrain psychological states. Are these psychological states produced by the molecular changes for are the so-lecular changes produced or in any way guided by the psychological changes produced or in any way guided by the psychological changes produced or in any way guided by the psychological changes produced or in any way guided by the psychological concirences. In other words, they are distinuiguabable (and the distinction is aboutle,) but not divamble.

duanction is absolute), but not divisible.

"The energy displayed by a gang of navies is not theirs, but their vicinals"; they simply direct it." In physiological language it is the outcome of the proper fractioning of their meaning of their propers. In the outcome of the proper fractioning of their meaning of their propers of the propers of the propers of the outcome outcome of the outcome outcome of the outcome outc

Now to say that mind, or will, or consciousness directs the organic energy along a definite path we regard as moureed, because it ignores a distinction which we hold to be whild and valuable, and conducive to clear thinking on these difficult subjects. But we have no such objection to the statement that

the energy is guided by molecular forces which have for their subjective aspect certain states of consciousness. To unscientific folk this may sound mere quibbling; but to physicists, who have done so much to teach us the vital importance of accurate language for clear thinking, we look for support in drawing this distinction, unless the distinction can be shown to be either myall of unless.

The datunction between force, energy, and the physical sense (what I have elsewhere spoken of as kensar) on the one hand, and thought, consacousnes, and the psychoial sense (what I have elsewhere spoken of as smallener) on the other hand, we have elsewhere spoken of as smallener) on the other hand, we have elsewhere spoken of as medicaries) on the hand, we have elsewhere spoken of the other hand, we have elsewhere the hand of the hand

Now, looked at from above, the wriging or supposed to reprevan the development, from winth, for wor and under store, of that complete form of kineses which we cull nearness. From this point of view, all is force and energy or kineses, and cun become nothing clie. Looked at from below, we have the development of connectioners. From what? We must not say jumping across the line, or, in other words, ignoring the disniction. From what, then? From those lower forms of "something which-is notypi-connecistories but which may-determ metakiness."

I have elsewhere endeavoured to show that this view is not open to the objection that, were the kinetic sequence in a continuous and determinate one, consciousness is merely a lypoulous, and that an annoneuson. Diversin might have written product, and that an annoneuson. Diversin might have written consciousness, though it is distinguishable from, it is according to enhypothesis, no less inseparable from, certain complex modes of the kinetic process. As the world it constituted, such of the kinetic process. As the world it constituted, such of the kinetic process. As the world it constituted, such of the kinetic process. As the world it constituted, such of the kinetic process. As the world it constituted, such of the kinetic process. As the world it constituted, such of the kinetic process. As the world it constituted, such of the kinetic process in the world in the kinetic process. The world is the kinetic process. The world is the kinetic process and the world in the world of living beings of the world of living being of the w

not be the same kineses but something allogether different. In other words, it is with cert am molecular transactions which have the or a constitute of the constitute of the

Law afraid that, as Prof. Lodge has accepted my "middle principals" accessly, he has failed to appreciate its point. For, if that paragraph is correct, the Professor's ascetton, "Force is certainly necessary to direct the motion of matter," is only a truum, similar to the important geometrical theorem, "In any right angled triangle, one angle is equal to 90". On the other hand, Dr. Croil's assertion, to the effect that guidance is effected the service of the professor of the pr

must have some independent definition of "force," and a issould very much like to know what that wewers "the cause in my last paragraph." Fred. Lloyd Morgan implies in his last letter that, in the case of the san altering the direction of motion of the earth, no energy is expended. This is, of course, only spgrounnetly true; and eren in the case of his twithing his stick round his finger and thumb, as the stick is elastic, its forces of contents. It was also that the stick is elastic, its forces of contents are considered in the stick is the stick is the stick is expensed by the stick is the stick is the stick is the stick is expensed by the stick is the stick is the stick is the stick is expensed by the stick is the stick is the stick is the stick is used to the stick is used to the stick is not all the stick is the stick

a string into action, it would be necessary to wait till two particles were moving on paths with a common normal—an occur-rence which must be infinitely rare. When Prof. Lodge says "an infinite mass can absorb any amount of momentum, with-out receiving a trace of energy, &c.," he forgets that the term "infinite" is only relative, "an infinite mass" being one whose "infinite" is only relative, "an infinite mass" being one whose change of velocity (or kinetic energy) consequent on a given change of momentum is negligible for the furfour in hand. It would not, I imagine, suit Prof. Lodge's purpose to suppose psychic forces might do a little work, so long as it was only a

payenic onces man the cold paradox, "What would happen if an irresultile force were brought to bear against an immov-EDWARD T. DIXON.

12 Barkston Mansions, South Kensington, July 24.

THE discussion on this topic has gained in clearness by Prof. Lodge's conceding that "the same question—What determines the direction of the transfer of energy?—may doubtless be asked in connection with inanimate activity,... but in neither case do I know the answer."

Perhaps some more precision may be attained by expressing the question in other words.

The principle of conservation of energy reigns over the

quantitative relations of all processes in nature, but it does not give any explanation of the qualitative changes of those processes. These changes and their conditions must in every case be found out by special experience. But, nevertheless, they are, in every accessible case, found to be subjected to fixed laws A given substance undergoes evaporation or chemical transformation-dependent on or necessarily bound up with changes of heat late energy of molecular motion, or into chemical energy, or wise verifical and a distinct degree of temperature, or under distinct conditions of electrical action. Inaphicable as these transformations of quality or form of energy remain for as, there is nothing undetermined in them, nother have we any right to such a supposition for the qualitative changes going on

right to such a supposition for the qualitative changes going on in plants and animals—their quantitative relations being like-wise governed by the principle of conservation of energy But there is another phase of the question Some unknown material changes in the brain are connected with phenomena of consciousness. Nothing can be more fallacious than to consider consciousness. Nothing can be more infracious than to consider consciousness as a form of energy, and to suppose it in a relation of equivalence to such forms. How it is, that what to our physical conception, or outer sense, are processes in the brain (which, as such, may be more clearly understood in future), are, (winch, as such, may be more clearly undicastood in future), are, at the anne time, to our psychood sonception, or inner sense, phenomena of consciounness, or acts of will, is a question beyond the domain of physical senerce, and capable of elisudation only by transcendental philosophy Whoever wishes for mote high there, must study the "Kritt der reane Peruntifi," especially the chapters "Von den Paralogismen" and "Die Autonomier." Antinomien,

Schopenhauer, and others after him, have considered our Schopenhauer, and others are filling have Considered that power of will, or our conscious directing of motion, as the key for all qualitative processes in nature, these being considered as, in their essence, acts of will. But this is cutting the knot by means of a metaphysical assumption

D. WETLERHAN, Freiburg, Badenia, July 27.

In reading over the remarks of Dr. Lodge and Prof Morgan upon Dr. Croll's views as to the direction of force, it appears to me that both have missed the point. Dr. Croll did not mean that a force at right angles to mother the two work, but simply more than a force Dr. Lodge says it is, although the exhowledges that the second force does no work. Further, Dr. Croll says, with regard to the find force, that is direction is crolled to the crolled specific the force of the crolledge states the second force does no work. Further, Dr. Croll says, with regard to the find force, that its direction is a first than the crodial paint before we get to a second force or to a right angle. I, fulfy acknowledge the importance of Dr. Lodge's pranciple, but it is not unply the indorsement of Prof Morgan thinks Dr. Croll's view no assumes a feet.

Prof Morgan thinks Dr. Croll's view no argument in favour theism. It does not prove that mind can or does affect of theism. matter Perhaps it does not directly prove this, but, within its range, it seems to me an effective reply to mechanical atheism. We see direction, and if this does not come from force it must come from some other source. We know of no other source but mind. To talk of mind affecting matter denies the essence of mind by which it is distinct from matter, and makes it a mechanical ab extra But try to banish it and it will come in

mechanical ab extra But try to bannan it and it was come in somewhere. "Tamen usque recurrer"

Dr. Croll's position seems to me to affect the first law of motion Uniform motion in a straight line is in no way comnected essentially with force, if his view is correct

Dr Lodge's principle appears to affect the second law of motion, and also the doctrine of impact and transference of force.

Further, it affects gravity. Gravity is always at right angles to the first law of motion, and therefore gravity is not a force; for that can not be a force which never exercises force.

Technical Education for Farmers, Farriers, and Engine-Drivers

KNOWING that you take very great interest in the various questions relating to technical education, I may give you a few particulars of an experiment which the Devon County Agriparticulars of an experiment which the Devon County Agri-cultural Society recently muled at its Exmouth meeting. Being desirous of giving farmer-, farmers, and those generally interested in the welfare of horses, some information on the scientific prin-ciples which underthe proper performance of the duties of the farmer, and the correct form and mote of attachment of horses' shoes, and also of giving farmers and engine-drivers some practical and scientific instructions on the working and care of practical and scientific instancious of the working and calculations are steam-engines, the boxiety approached the County Council with a view to a grant in nid of their object. The proposal was very a view to a grant in mot of their origins. The proposal was very warmly taken up by Mr. Lethbridge and office gentlemen who are well known for their active inferest in education and other matters important to the welfare of the county, and a grant was obtained

The Society secured the services of Prof F Smith, head of the Army Veterinary School, Aldershot, and of Mr. W. Worby the Army Veternary School, Adderstoit, and of air w. wordy Beaumont, and by these gentlemen lectures were given on each of the three days of the Society's meeting at Exmouth The weather was very unfavourable on two days, but notwithstanding this the attendance at the lectures was large, and on the second and third days was larger than was expected, and was fully up to the accommodation provided. The audiences were remarkably attentive and appreciative, and in every respect the experiment proved successful. Many who were sceptical before the lectures of their value to working men, became convinced that not only is it possible to give working men information which is useful in is it possible to give working men information which is useful in an iniportant degree in their daily work, but that the inen are themselves quick to appreciate its value. I may mention that on one of the days nearly two hundled shoeing smiths and a large number of farmers attended the horse shoeing lectures, and on one day seventy-eight engine drivers entered for the lecture on the steam-engine, and there were also in attendance a

Totacs, July 20 John JOHN L. WINTER.

THE ERUPTION OF VESUVIUS OF JUNE 7.

THE suggestion that I published in several newspapers has been fully confirmed-namely, that the second alternative type of eruptive character would be pursued by the volcano Now for a period of over a month lava has continued to dribble forth, activity has returned to the central vent, and no great changes have occurred

The throat of the volcano commenced to be cleared on June 9, the vapour forcing its way up from the crater bottom through the choke of loose materials, and rose above as a column carrying with it much dust; at the same time the powerful vapour blast issuing from the upper extremity of the lateral rift, of which mention is made in my first letter, soon stopped Each day I was kept informed of the state of the volcano by the kindness of Messrs Ferber and Treiber, the director and engineer respectively of the Vesuvian Railway
On June 15 I considered it right to again visit the

mountain, and had the good fortune to be accompanied by Messra. H. Elliot, A. Green, Landen, Newstead, and Treiber, several of whom are excellent photographers, so that with two of my own cameras we were able to make an extensive pictorial record of some very unique

At the point of issue of the lava, at the junction of the foot of the great Vesivian cone and the Airio del Cavallo, the first lava had cooled sufficiently to walk over it, but beneath our feet could stull be seen in a few holes the dowing lava. At the foot of the great cone, and of the great cone, and of the erupture ent, as if this had continued so far, were a series of driblet cone fumaroles. We counted seven complete and well-formed casamples, besides numerous aborture ones. Most were giving out intensely heated beneath, and which soon carbonized a piece of wood placed in it. Around the lips of the upper opening, hematite with fused chlorides of potash, soda, iron, if

of scoria from the vapour that otherwise would escape after its exit Leucite I have also demonstrated to be formed while the magma is simmering under low pressure with free escape for vapour in the upper part of the volcanic chimney 1.

At the summatof the great cone the crumbling in of the edges was constantly going on, but the upper extremity of the lateral rift at the fost of the cone of eruption and at the summit of the great Vesuvian cone had nearly cassed to give forth vapour. Along the line of rent on the mountain side no financiole or other signs of activity were visible except quite at the foot, where those commence of which have souked.

Up till June 20 there was a struggle to clear the upper part of the volcanic chimney of the impeding materials, which were constantly being added to by the slips from the cratter's edge, but on that evening a dull red glow was visible in the cratter bottom, showing that a fairly clear passage had been temporarily made for the continuous escape of vapour, and also that the lava was at no very

copper, &c., were being condensed from the vapour, and trickling down the outer surface of the fumarole, consolidated as curious vari-coloured stalactites of very deliquescent nature.

The lava had first flowed towards the escarpment of Monte Somma in a fan-like manner, so that the eastern extremity reached that great natural section just beneath the Punta del Nasone. Still following the natural inclination of the ground, it turned to the west, and on june 15 was opposite dyke 16 (as marked on my large geological map just published, and on the dykes themselves), advancing at a very slow rate.

The lava is a virrous and coarse-grained rock, especially in regard to the included leucite crystals, whils it is surface is, with one exceptional tongue, of the corded or "pahoehoe" type. This is due to the magma being one that has been simmering since January in the chimney of the volcano, so that most of its dissolved H₂O has been boiled off, and so allowing it to cool without the formation

great depth from the summit of the volcano. This of course indicates that the lateral opening was in-sufficient to drain off much of the larva which occupies the chimney above the level of the lateral outlet. Had such executation really taken place, the eruption would amount of lava above the rap, but more from frothing up of that below that level in consequence of the relief of pressure that in that case would occur of (course, during all these days the ejection of dust with the smoke occurred, guying the latter that peculiar dark grey colour occurred, upon the latter that the case or city could place, so as to partly block the outlet, and it was not till our next visit that it again clearly, and it was not till our next visit that it again clearly.

On June 30 I again visited the crater, in company of my friend Mr A. Green All the summit of the great cone

"See H J J L "Geol M Somma and Vesuvius," Q J G S, vol xl and "Relationship of the Structure of Ign our Kecks to the Conditions of their Formation," Second Proceed R Publin Soc, vol v, N S was covered by a thick coating of dust and sand, upon the surface of which were the usual white and yellowishgreen chloride crusts seen on such occasions, so rich in coper as to plate with that metal the iron nails of our boots. The crater had considerably enlarged, the edges were in the compared to the compared that, with a slight push by a stick, it was possible to detach large masses of the materials which form the sides of the crater in the recent cone of eruption. So danger-cons were the edges, that it was but in two places that my experience indicated as being safe to approach and look over, and that even with several precautions; so that the here but a few hours after our departure, is not to be wondered at.

On looking down some 45 to 50 m beneath us, we could see the glow from a mouth some 2 or 3 m. in diameter. The walls of the crater were concave, so that athough overhanging at the top, yet a plumble included the crater bottom was roughly plain, due to the combination of a talus all round, and an attempt at a cone encurling the main vent. It will be thus seen that the crater cavity was of the form of a convex-sided cylinder, or more simply was of the form of a convex-sided cylinder, or more simply

barrel-shaped, with its upper diameter some 50 to 55 m.
With much difficulty we made our way around to the north side of the cone of eruption, which had now lost its usual loose scoria surface, which was buried beneath a thick coat of sand and dust, covered with a thin saline crust on its surface The upper limit of the radial rift, which we were prevented from examining three weeks previously, on account of its giving out so much vapour as to constitute the temporary escape aperture of the volcano, had now become quiescent, so that we could fully examine it. Only a current of hot air was now issuing from it, but I was able to collect some fine masses of crystallized molysue and kremersite from its edges. Its average breadth was about 0 50 m, where it traversed old compict lava, but of course it disappeared as soon as it reached the looser materials. The real azimuth of its orientation, which we could now determine with greater accuracy than when we were walking over hot rock and enveloped in hot irritating vapours, proves to be, as it radiates away from the axis of Vesuvius, about 15° west of north. It curves then a little to the north, and near the foot of the great cone it again assumes nearly the same azimuth as at starting, an arrangement which is quite evident when the Vesuvian cone is regarded from the Punta del Nasone From that, the highest point of Somma, the lower extremity of the rift lies a little to the right or west, and faces that part of the Somma ridge which corresponds to the upper extremity of the Vallone Cancherone

In the forenoon of June 30 much dust had fallen at the lower railway station, of which we collected some bagsful. It is the usual fine sandy material of these eruptions, and consists of the pulverized materials of the cone of eruption.

Having passed the night at the lower railway station, the next day we crossed the Artin, ascended to the western extremity of the ridge of Somma, and followed it along so as to get a general burd's-eye trew of the whole scene of the eruption, and take photographs of the more important points. As one stands on the Purta del Nissone and embraces that magnificent view of Vesuvius and the Artin old Cavallo, one sees at their feet the new to the control of the ridge we found a thin coating of the ridge we found a thin coating of fine red dust which had reached thus far from the crater. Much of the Artino was also covered by the same material. Scaling the chiff face just beyond the Cognillo

di Ottajano to the Atrio del Cavallo, we again visited the lower point of the outburst. Most of the beautiful fumaroles were in a state of ruin, and lined by good-sized crystals of hematice and mixed chloride criests. Here the lava was quite solid, though at one point was a hole, some 50 m. from the base of the great cone, where we could see the molten rock flowing lazily along about a metre beneath our feet. The lava at the end of the flow was making considerable progress to the westwards, and stood outboatt divke 13.

and stood opposite dyke 13
Since then, few changes have taken place in the mountain: the crater still gets larger, dust is thrown out, and the lava descends. These phenomena are capable of continuing for months if the drainage opening does not

As the eruption progresses, I will send you further details.

H J JOHNSTON-LAVIS.

THE PRODUCTION OF MUSICAL NOTES FROM NON-MUSICAL SANDS

THAT I have succeeded in producing musical notes from sand that was never before musical, and am also able toproduce similar results from certain mute or "killed" musical sands which have been temporarily deprived of their musical properties, has already been announced in the Chemical Wexty (vol. buy No. 1620).

It is not necessary now to gwe the details of the miserous experiments which led up to this discovery; it will be, perhaps, sufficient for present purpose, it will be, perhaps, sufficient for present purpose, which is propounded a theory to account for the cause of musical sounds issuing from certain sands. After giving avrous reasons for my conclusions, I said—"I to occurred to me, then, that the music from sand was simply the operation of the prefectly default and the proposed of the perfectly default given from the proposed of the pr

Having described numerous experiments, and drawn attention to the hopeful results obtained from the "millet-seed" sand, my paper concluded with the following.—
"From what I have now told you, I think we may conclude that music may be produced from sand if (i) the grains are rounded, polished, and free from fine fragments; (2) if they have a sufficient amount of 'play' to grains are perfectly clean, and (d) if they possess a certain degree of uniformity in size, and are within a certain range of size."

On June 20 last I visited Studiand Bay for the purpose of carrying out some new experiments. I found that the musical patch emitted tones louder and more pronounced than I had ever heard them there before. The best resulting the properties of the sand; sounds produced in this way were heard unmistakably for a considerable distance. The patch wareaged 7/2 yards in width, and ran parallel with the trend of the shore for some hundreds of yards. The trend of the shore for some hundreds of yards. The notes of a high purch; that on the land find evan coatte, and emitted notes of a lower pitch. The rod drawn across the patch gave, therefore, a great variety of pitch. Many other interesting facts cannot now be referred to, but it is important to state that some of referred to, but it is important to state that some of some patch. The rod drawn of the patch of

1 Read before the Bournemouth Society of Natural Science

notes of a low pitch, but the fine was mite. This was, so far as I know, the first time that the Studland

sand had been musical of the patch.

According to my theory, if the number of grains with polished surfaces could be increased in this fine sand, the number of vibrations would increase also, and so intensify the note, and cause it to become audible, this could only be done, however, by introducing a certain percentage of grains fulfilling the required conditions. To obtain such grains and to introduce them gradually until the necessary number should have been added. would have been a tedious process; and it occurred to me then that the same result might be obtained if the sand were struck in a vessel with a hard and polished interior I placed, therefore, this fine sand in a teacup, and on striking it, found that it emitted a high, shrill note (A in altissimo), which was far more intense than that given when it formed a part of the patch.

When polished grains of sand are in contact with the sides and bottom of a glazed porcelain vessel, it is obvious that there are numerous points of contact between two polished surfaces-the sand grains and the vessel-and that on striking the surface of the sand, the friction necessary to produce the vibrations of a musical note is

induced between these points

This I proved by placing the same sand in various vessels with rough interiors, and by lining these glazed or polished vessels with silk, &c, but in no case would this sand emit notes unless the grains were in direct contact with the glazed or polished surfaces This pecuharity is not in any way dependent upon the sonorous properties of the vessel used, for it may be "deadened" with impunity, and the note will remain unaltered

The results of numerous experiments show that musical sand of the Eigg type—ie sand possessing in great per-fection the physical conditions necessary for the produc-tion of music—will be musical in receptacles of whatever composition or form, though in some of these it emits notes "under protest" only 1

Those sands which are of the Studland Bay typehaving the necessary physical conditions less perfectly developed, and are usually mute except in situ-will emit music only in vessels possessing hard and glazed interiors. and, as a rule, of a certain form, while some of the more "sulky" types of sand not only need a vessel of hard and glazed interior, and definite form, but also require a box, or small pedestal of wood (which I call a "coaxer"), on which this vessel must stand before the notes emitted become audible A "sulky" sand was rendered far more musical by being sifted, washed, and boiled, giving out, after this treatment, notes without the aid of the coaxer."

After discovering what could be done with such simple apparatus, it occurred to me to try, under similar conditions, some of my abandoned sands-those unmusical sands that had been, during a period of four or five years,

treated unsuccessfully for music

One sand (an iron-sand composed of more or less polished grains, quartz, and much dust formed of denser minerals) gave a very hopeful "swish" (explained in my paper of 1888) in a certain porcelain vessel, and from this-by (1) sifting in sieves, to eliminate the fine material, and to insure uniformity in size of grain; (2) rolling down an inclined plane of frosted glass, to separate the rounded grains from the angular quartz, and (3) boiling in dilute hydrochloric acid, to cleanse the surfaces—I succeeded in producing a sand that, in certain glazed vessels, emits musical notes as clear as those emitted from any of my

NO. 1136, VOL. 44]

musical sands but that of Eigg This sand gives Fin allussimo, but it very soon becomes "killed" because of the fine dust and loss of polish that is the inevitable result of the attrition of the grains. There remains but one thing to be done, and that is to produce a sand which, like that of Eigg, will be musical in almost any receptacle, and I have reason now to think that this will not be very difficult

It has not been possible here to record more than the merest outline of what has been done, or to give instances of the interesting capriciousness of these sands: it should be understood, however, that no ordinary beach or cliff sand has the slightest inclination to "sing" under any of the "coaxing" methods at present known to me

CECIL CARUS-WILSON.

NOTES

SIR MICHAEL HICKS BEACH, who previously gave a negative answer to the request made by the Executive Committee of the British Institute of Preventive Medicine, having reconsidered his decision, has now granted the required license to register the Institution as a Limited Liability Company, with the omission of the word "Limited" The license, however, is not to be construed as expressing approval by the President of the Board of Trade of experiments on animals, or in any way affecting the exercise by the Secretary of State of his discretionary powers to grant a vivisection license to the proposed Institute The articles of association have been signed, and the Institute is now duly registered. The following gentlemen have already expressed their willingness to serve on the Council Sir Joseph I ister, Chairman, Sir Charles A. Cameron, Mr. Watson Cheyne, Prof Michael Foster, Prof Greenfield, Prof. Victor Horsley, Sir William Robeits, Sir Henry Roscoe, Prof. Roy, Prof. Burdon-Sanderson, Dr. Pve-Smith Dr. Armand Ruffer, of 19 Iddesleigh Mansions, Westminster, SW, will act as honorary secretary until the first meeting of the Council.

THE graduation ceremony at the close of the summer session of the University of Edinburgh was held on Monday. Principal Sir William Muir, Vice-Chancellor, presided. Prof Kirkpatrick presented for the honorary degree of Doctor of Laws Colonel Sir Colin Campbell Scott Monerieff, K. C.M.G., C.S. I. R E., remarking that, through his work as chief officer of the irrigation works of the Nile, it could be said that Sir Colin had created a greater and an infinitely freer, happier, and more prosperous Egypt than it was before As a gallant officer, a distinguished man of science, a statesman of high merit, and, above all, as a benefactor of his fellow-creatures, Sir Colin was pre emmently worthy of the highest of their academic honours. The honorary degree of Doctor of Law was then conferred in abuntal on Prof. Simon Newcomb, Washington

SIR JOSEPH FAYRER has been elected a Corresponding Mcmber of the Royal Italian Society of Hygiene Sir Joseph has also been promoted from the grade of Foreign Corresponding Member to that of Foreign Associate of the French Academy of Madicine

PROF. DU BOIS REYMOND, the distinguished physiologist of Berlin, has been awarded the Gold Medal for Science.

MR. J. E KEELER has been elected Professor of Astrophysics in the Western University of Pennsylvania, and Director of the Allegheny Observatory Mr F W Very is associated with him as Adjunct Professor of Astronomy. It is expected that the Observatory will continue its researches on important problems in the domain of asiro-physics.

IT is stated that Slam, following the example of Japan, is commencing to Europeanize her institutions. The founding of

[&]quot;When muscal rand, count "under protes" they give out high, shrift become in a thinbleful of the Eigs and. "Small quantities east not easily a pick high pick high protest and are quickly "whilet" by constant strings. By an-the harder muscals present abrade the softer as they rub bayerber, and this forms a fine date.

a University has been decided upon, and Prof. Hasse, of Konigsberg (Germany), has accepted the appointment to the Chair of Physics.

THE last number of the Rendsconts of the Reale Accademia del Lincel contains an account of the annual meeting held on June 9, at which the King of Italy was present. After the opening speech of the President, Brioschi, one of the chief features was an admirable address by Prof. Measedagkin on the Homeric urangloocy, with speech reference to precession.

La Revue Scientifique of the 1st instant contains the address by M. Villemin, the Piesident of the Tuberculosis Congress, It deals with recent researches. The results of the first Congress are also detailed by M. Petit, the General Secretary.

A FIRAL meeting of the Committee of the Virchow Testimonal Fund took place on Joly (5, 5r James Fage, Bar 1, F.R.S.) in the chair. The Treasurer gave an account of the moneys received, which amounted to about 4.75 ft was resolved to send this sum to the General Treasurer of the Fund, and to preem For Virchow on the occasion of the hardsday with an illuminated sideres, conveying to him the congentualtions of the Committee and subscriber. This the Honosary Secretaines, Dr. Semon and Mr. Hotsley, were directed personally to transmit to Berlin on the occasion of the Celebration

This Essex County Council has appointed an Organizing Jonn Committee, constaint of air members of their own body and six members of the Two my body and six members of the Essex Field Liab, to form a centre for employing lectures and teaches; both apparatus and maternals), conducting examinations, and affording help and guidance to local bodies, in connection with the recent grants towards technical instruction. A grant of 2900 has been made for these purposes. The members of the Committee are (representing the County Council) Mr. is. N Buxton, Mr. F. A Fitch, Mr. B. Whittingham, (for the Fixes Feeld Crub) Prof. Londger, Mr. F. Chancellor, Frof. R Meldola, F.R. S., Sur Henry F. Roscow, M.P., F.R.S., Mr. F. W Kudler, and Mr. J. C. Shentione. The Organizing Secretary to the Committee is Mr. W. Cole, 35 New Broad Street, L.C.

THE idea of "a British Museum of Portraits," to be executed by photography, was conceived as long ago as 1864 by Mr. James Glausher, F R 5, and brought before a meeting of the Council of the Amateur Photographic Association, of which the Prince of Wales is the President The suggestion was cordially approved by the meeting, and photographs were taken in carte de visite size and deposited at the South Kensington Museum, At first, however, only fading silver prints were made, and these were so unsatisfactory that for some years the undertaking was held in abeyance By the discovery and perfection of the process of permanent carbon printing, an opportunity has at length been afforded of resuming the prosecution of the work under infinitely more favourable conditions, and, as a result, a collection of excellent portraits is now being made by the Amateur Photographic Association Already there are nearly 200 large permanent carbon portraits deposited in the Art Department at the South Kensington Muscum, and about as many more are ready to be sent. These latter were on exhibition at a private view on Saturday last at 58 Pall Mall, S W., the studio of Mr Arthur J. Melhuish (Photographer Royal) They embrace some photographs of men of distinction in science, and are excellent both as likenesses and as specimens of photographic art The conditions under which they are taken are, in fact, sufficiently exacting to insure the production of a faithful portrait, inasmuch as every portrait must be approved by the sitter and by the Standing Committee previous to its being placed in the South Kensington Museum. The undertaking is on a non-commercial basis, the photographs being taken for the purposes of this collection only, and not for publication, and no expense of any kind being meurred by the sitter. The invitations to sitters are usued under the authority of the Council.

That Trustees of the Indian Museum, Calentis, have just sende the second and concluding portion of a Casicogue of the specimens of Mammals contained in that Institution. The first volume of the Catalogue, complete by Dr. John Anderson, the late Supernstendent, was published in 1881. The present volume, which commences with the Rodentis, has been prepared by Mr. W. I. Scaler, the present Deputy-Superintendent. The total number of specimens of Mammals contained in the Indian Museum, as is shown in the Catalogue, w 4872. These are referred to 500 species, of which, 276 are found within the limits of the Indian Empire, and the remainder are from either the Catalogue, and the Catalogue of the Catalogue will be of much use to students of the cours of Mammals.

FOR the first time for many years the Journal fur Ornithologia has actually appeared within the month imprinted on the cover bearing the date of publication. English ornithologists have this year received in July the Heft bearing the date 'Iuli, 1801' Gott see dank. The articles published in the present year appear also to be of a higher class than many of those formerly round in the Journal, and some very important papers by Dr Reichenow, Dr A. B Meyer, Herren Schalow, Hartert, &c . have been published. The chief interest centres round the collections which that greatest of modern naturalist explorers, Emin Pacha, has sent to Beslin, and the birds obtained by him during his journey from Bagamoyo to Lake Tanganyika are fully described by Dr. Reichenow The novelties are not many, but are sufficient to show that there is much to be done in German hast Africa before our knowledge of its ornithology approaches completion English naturalists will await with engerness the 70 slogical work of our Consul in Mazambique, Mr H II Johnston, C B, for the whole of the district in his sphere of influence is practically unexplored as far as natural history is concerned, and at present our knowledge is almost a blank To Mr Johnston and his companions, therefore, English zoologists are now looking for information which shall connect the work of Bohm and Emin with that of Kirk and Livingstone

IN a recent paper to the Soutif des Ingénieura Civils, M. Habitumans stave, that in London the cost of the electric "bone hour" in 0.375 france, that is three times the cost of gas I to Perrais its 0.90 france, and at Saunt Beneue, the towas where, results it to 90 france, and at Saunt Beneue, the towas where, sauce June 1 law, it is cheaper in France, it is still 0.54 france, and o 10 frances for a comamption over 20 horse-power. Such difference, he point out, do not are from difference in cost of ordinates of the first part of

IT is stated that a memorial is about to be presented to the United States Congress asking for the creation of a Government Department of Public Health, with a Cabinet officer at its head, to be known as the Medical Secretary of Public Health

The Danah Academy of Scences has recently offered the following among other prise — A gold medil, worth about £17, for an exposition of the theory of electric whrations in immed and resting boldes in general, with a special application to simple forms of perfect conductors, so that for these cases, the mathematical problem may be explained, and if possible solved. A prize of about £2z, for an investigation showing in the case of our four principal cereals, the nature, and as far as possible the proportional quantities, of the chief carbohydrates for different stages of ripeness. Memoirs to be accompanied with preparations. A prize of about (27 for a complete account, accompanied with preparations, of the Phytoplacidia found in Denmark, and a monographic exposition of the species of the genus Phytoptus (in its old and wider sense), which inhabit the various galls, found on a particular plant, with the view especially of showing whether several usually different galls of the same plant species arise from the same Phytoplus in different phases of its development. In choosing a plant, preference should be given for one in which these galls have an economic value, as is the case, eg, with some occurring on the beech Further, the Academy desires an exposition, as complete as possible, of the development of a particular species of Phytoplus. The date for the first is October 31, 1892 , for the two others October 31, 1893 Memoirs may be written in Danish, Swedish, English, German, French, or Latin

The furtheh Jahonowsky Gesellichaft, recognizing the fact that the determination of the secular perturbations of the orbits of the interior planets, in the form in which they have been felt by Le Verrier, are not satisfactors, and that probably the anomaly in the motion of the perhelion of Mercury is to be explained by the fact that the differential equations have been treated interzally, offers a prize of 1000 marks for a new determination of the exist of Mercury, Venns, the Earth, and Mars, in which the terms of a higher order are taken into account Competition, are to send in the results of their interactions before November 1894, observing the usual rules to secure the annoyment of their papers.

THE Educational Times states that the Supreme Council of Hygenes of Austra has been engaged in discussing the advantages of erect as compared with slanting writing, and the official Report of Drs von Resis and Lorens points strongly in favour of the former. They point out that the direction of the written characters has a marked influence on the position of the body. In "straight" writing the scholar faces his work, and is spared the twist of the body and neck, which is a laway observable in those who write slantines, and one common cause of spinal curvature is this obstanted. The erect method is, therefore, expressly recommended for use in schools, in preference to the ordinary sloping lines.

WE have received the eighteenth Annual Report of the Geological and Natural History Survey of Minnesota I: consists of a summary statement for 1889, report of field observations made in 1888 and 1889, by N If Winnchell, American opinion on the older rocks, by A Winnchell, additions to the library of the Survey since 1884, and a list of publications of the Survey.

L'Électurit points out that the new electric photosphore, which consuss of a small glow lamp at the end of an elastic tube used for throwing a strong light for surgical purposes into the mosth, ear, &c., was really suggested by the action of the water jet in the luminous fountians now so common, and that these really owe their origin to a laboratory experiment by M. Becquerel in 1896.

HERK KENYZ, we learn from a German source, has been making inquiry into the digestibility of different kinds of cheese. The most easily digested, he found, were Cheshire and Roquefor; while others are ranked as follows, in ascending order of difficult digestion. "Emmenthal, Goognousle, Neuchkiel, Ramadour, Rotenburg, Mann, fromage de Brie, and (most indigestible of all) Swiss cheese.

In recent numbers of the American Journal of Science (February 1891) and Ciel et Terre (July 1 and 16, 1891) attention is drawn to the remarkable conclusions arrived at by Dr.

Brutker in his work entitled "Klimaschwankungen"—the most complete work extent upon the question of the variation for climate—in which he shows that the climate has not undergone any continuous waration from the easiest hatonic time, but that it oscillates, and presents alternately periods of heat and odd, and of dryness and humstlity, the period being about 35 years, which, it will be observed, as multiple of the period of frequency of varianging the control of the period of sequency of varianging the tits of years. When the period of frequency to variate the control of the period o

PART 34 of Cassell's "New Popular Educator" has just been issued, and contains articles on applied mechanics, algebra, botany, electricity, and comparative anatomy

MR G. C. HOFFMANN, of the Geological and Natural History Survey of Canada, has made a microscopical and chemical examination of a peculiar form of metallic iron found on St. Joseph Island, Lake Iluron It appeared in the form of spherules disseminated through a thin deposit of dark reddishbrown limonite which coated certain faces of some surface specimens of quartz. These metallic looking spherules were found to consist of nuclei of silicon conted with a humus like substance, which in turn was overlain by a metallic layer containing all the elements most frequently met with in meteoric But the small proportion of nickel present to 11 per cent), and the relatively large amount of phosphorus (1 o7 per cent), as also the fact that the subcrules contain nuclei appuently of a concrete character, leads Mr. Hoffmann to suggest the possibility of a terrestrial source for the material, upon the assumption that it has resulted from the reduction of an iron salt by organic matter. The paper, which is accompanied by four coloured plates, appears in the Transactions of the Royal Society of Canada, 1890

life preliminary results of some investigations upon the growth of the face are stated by Prof G M West in Science for July 3. The values obtained in the case of measurements of the female face point to the existence of three distinct periods of growth, the first ending at about the seventh year, and the third beginning at about the age of fifteen. The abrupt transition from one period to the next is indicated by the very slow growth of some children until the ages of eight or fourteen, when a rapid development often occurs. From the fifth to the tenth year the average growth appears to be about 65 mm During the next four years it is 6 2 mm, and from this time little advance is made, the maximum of 128 mm being reached at about the age of twenty I he male fact is larger than the female face at all ages Its growth is also more rapid, and continues later in life. The measurements have been on 2500 persons, including both sexes

PROF TITO MARIINI, of Venice, contributes to the issue of the Rivista Scientifico Industriale for the end of June, the results of some experiments on the crystallization of thin liquid films He finds that a strong solution of sodium sulphate, when cooled to near its saturation point, possesses a viscous character which enables it to form a thin film on a metallic ring, as in Mr Boys's experiments with soap bubbles On rapid evaporation such a film crystallizes to an extremely beautiful open jattice-work of minute crystals, which preserve their transparency for some time, and then effloresce and crumble to powder The experiments succeeded with rings up to thirty-six millimetres diameter Similar experiments with ainmonium chloride and sodium hyposulphite have hitherto proved unsuccessful. With a transparent film of liquid sulphur, however, even more beautiful results have been obtained. The author regards such experiments, besides being eminently suitable for lecture demonstration, as likely to throw light on the nature of molecular arrangement in relation to crystallization

THE same number of the Kiterica unmarates a somewhat important communication to the Naples Royal Academy of Physical and Mathematical Sciences, in which Prof Dino Publication and the situation of the American Communication of the Janac of oscillation of Foucault's pendulum in relation to the earth's rotation in lumificent. The author contends that the problem for latitudes between the pole and equator is more cannot be solved by the principle of inertia. He proposes an equation derived from the principle of composition of the rotational forces.

A METEROLOGICAL Journal in the Ressum language, the Meterological-keith, Witthin & Menesneger, has lately appeared under the competent editorship of Weelloof, Rykauschew, and Spender, ris general prias seems to be like that of the German Zentzhrift. The idea of statting it across at a meeting of the Russian Naturshits and Physicians at St. Peterships in the end of 1859. Four graphic tables are given in this journal, showing the course of the meteorological elements during 1859 at the agreedural experimental station of Sapolje, also measurements of ground temperature, &c.

THE Schlowe Scraty's Magnatus for July contains the first of series of articles on the Kew Museum by Mr. J. R. Jackson; others on the effects of neuronment on plants, and other increasing matter. Among the correspondence are complaints from Warnetchine that the Wild Birds Preservation Act is added letter there, as the "studentime," whoever they may be, take no trouble in the matter. On the other hand, the inhabitant of Schlanda set fully after to it.

THE last volume (axin, 6) of the Trudy of the Society of Manualists of Kann constains the second part of Mr. Korrchinsky valuable retearches into the nonthern limits of the black-earth seppe region of East Russis. In the first partipublished in 1885, the author gave the results of his explorations in the province of Kann. He now confirms his conclusions by further exploration in Samara, Simbirsk, Pern, and Ufa. He are given the northern limits of the black earth steppe vegetation, and shows that they depend neither upon climate nor upon the altitude, but chiefly upon the course of the river.

ACCORDING to La Nature, the telephonic service of Paris, rapidly developing of late, will soon include an immense central telephonic office in the Rue Gutenberg, capable of serving directly 30,000 subscribers, without connection with the other offices of the quarter The work is being actively pushed forward. Cables are being laid in the sewers, an enlargement of which, at certain points, is rendered necessary. There were 7800 subscribers in Paris last October Paris lias now telephonic communication with Brussels, Marseilles, Lyons (which also communicates with Marseilles), Lille, Havre, Rouen, and London. Twenty-eight towns in France have a telephonic system. There are two in Algeria, in Algeria and Oran. Lille and Roubaix, Lille and Dunkirk are connected by telephone and, ere long, connection will be formed between Lille, Valenciennes, Calais, and Fourmies, between Lyons and Saint Ettenne, between Dieppe and Rouen, between Marseilles and Nice

The climate of the Greek island. Cephalona has been lately described by Dr. Pattack (**Zermann*** Afril.**) We note the following features: At Argustol temperature reaches a maximum in July (2, 3 °C,) whereas Corfu and Pattant does so in August. With several days' calin and bright sumbine, in the buy, the air, laden with moisture, becomes unbearably hot and close Yet the nativer go but little to the wooded halls behind, where the temperature goes down sometimes to 15° 5°C. or lower. Males bing down asometimes to 15° 5°C. or lower. Males bing down asom qilghty, in summer, from covered puts in the

hills, for supply of restaurants, &c. As to rain, there is a sharp contrast between the wet winter-half and the dry summer-half of the year The annual rainfall (36 years) was about 35 inches. The autumn rains are ushered in by severe thunderstorms. November and December are the wettest months, but about Christmas there is usually a short time of fine weather. March is extremely variable, and often very cold With May begin the rainless months, and the drought is sometimes considerably over 100 days Five months have sometimes passed with but a few slight showers On this greatly depends the currant cultivation a brief downpour may spoil the crop Snow falls seldom in Argostoli, but often on the bills. Dew is plentiful in summer. but its salt precipitate is feared. Wind is greatest in winter, southerly winds prevailing, especially south-east A hot south wind (the lambalitta) blows, rarely, in early summer, and with evil effects to vegetation The fresh north-west wind (maestro) brings cumulus clouds on the hills

MR F HOWARD COILINS, the author of a useful epitome of Mr Herbert Spencer's system of philosophy, has written a pamphlet in which he discusses the causes of the diminution of the jaw in the civilized races. In opposition to the views of Weismann, he contends that the phenomenon is due to "disuse"; and the argument, as he presents it, deserves to be seriously considered. Some time ago Mr. Collins sent to NATURE a letter in which he gave some account of the ideas which he now expounds more fully. In the preface to his pamphlet he seems to imply that the letter was not inserted because, according to a belief said to be current among certain biologists, the editor of NATURE is "more willing to publish letters contending that acquired faculties are not inherited than those contending that they are " Mr Collins has too readily allowed himself to be influenced by the belief of "certain biologists" If he supposes that it is possible for the editor of NATURE to print all the letters sent to the paper for publication. he must have a very madequate conception of an editor's functions

To throw light on some physiological processes, Herr Hofmeister recently experimented (Archiv fur experim Pathol) on the swelling of plates of gelatine in various solutions ; the plates heing taken out from time to time, dried, and weighed salt solutions of various concentration, the gain of weight was large in the first days, then gradually fell off, as in former experiments with pure water. The effect varied with the nature of the salt, and even with solutions holding the same number of molecules in 1000 parts water, the swelling varied as much as five fold. This difference, it is pointed out, is related to attraction of the salt for water, the greater the attraction, the more difficult the entrance of water into the plate. But that this is not the only factor is proved by the swelling in pure water being always much less than that in the solutions. Experimenting with ordinary salt, the gain of weight proved to consist both of water and salt, both dependent (but differently) on concentration With increase of the latter, the gain of water rises to a maximum (about 13 per cent.), then declines ; but the gam of salt goes on always increasing proportionally to the con-The remarkable property salts have of increasing the gain of water beyond what occurs in pure water is also shown by indifferent organic substances, as cane-sugar and alcohol. Experiments were further made on swelling of gela tine plates in methyl-violet solutions, and with the result that the concentration of the solution in the plates was always much greater (over 30 times) than that in the solution presented. The colouring-matter is taken up in relatively much greater quantity than the water Further, gelatine takes up somewhat more colouring-matter relatively from a dilute than from a concentrated solution. The forces concerned in these phenomena, and which are neither purely mechanical nor ehemical. Herr Hof meister brings into analogy with those occurring in absorption of gases by liquids, the reciprocal solution of liquids, adsorption of gases on solid bodies, &c

THE Photographic News quotes the following from the Scientific American, December 0, 1848 :- "New Electrical Light -The inventors of a new electrical light, exhibited at the Western Literary Institution, Leicester Square, London, on its recent reopening under the new auspices, expect, it is said, to apply it generally to shop and street illumination, and they state that, while the conveying will cost no more than gas, the expense of illumination will be one-twelfth the price of the latter light The current of electricity, in passing through the two pieces of chargoal which form the poles of the circuit, and are excluded from all access of air, gives, in this case, it is said, an intense and beautiful white light, with the effect of daylight, to a much greater extent than the lime does, and having this advantage, that it is sustained and continuous. If Messrs, State and Petrie can thus produce a steady and sustained light they have accomplished what has hitherto been the sole preventive to the substitution of galvanism for gas The Mechanics' Magazine states that this one light completely eclipsed ten gas lights and an oxyhydrogen The gas companies had better look out. The dissatisfaction of the public with their mismanagement may have begotten a rival destined to eclipse many more than merely ten of their gas lights."

WITH the view of certifying to the efficiency of teachers of public elementary schools to give instruction in woodwork in accordance with the provisions of the Code (1890), the City and Guilds of London Institute is prepared to issue certificates to qualified teachers of public elementary schools on the following conditions -The candidates will be required to give evidence of having regularly attended during each of two sessions, a course of at least twenty practical wood-working lessons in a school or class certified by, and under an instructor approved by, the Institute The candidates will further be required to pass an examination at the end of each year's course, to be conducted liv examiners appointed by the Institute, and to pay a fee of five shillings for each examination. For the first year, candidates who have attended an advanced course of instruction will be exceptionally admitted to the second year's examination without having passed the first, and will be eligible for the teacher's certificate. The examination fee for such candidates will be ten shillings. The written examination will include questions founded on such subjects as the following :- Woods. -Places from which some of the commoner woods are obtained. Their characteristic properties and uses. The general structure of cone bearing and leafy timber trees. The meaning of seasoning timber. Effects of thrinkage and warping. Identification of specimens of wood The questions will be limited to oak, ash, elm, beech, mahogany, sycamore, basswood, white deal (spruce), red pine (Scotch fir), yellow pine.

Das Watter for July reports a curious case of globular lightning which occurred at Berga, near Schlieben, in Germany, between 3 and 4 o'clock on the morning of July 1. The lightning entered the chimney and split into two parts, one portion ran along the rafters of the roof, and the other entered a bed-room occupied by a man with his wife and three children The man, who was up, on account of the violence of the storm, saw the ball jump on to the bedstead, which it broke, and from there it slowly travelled to the opposite side of the room, and disappeared, with a loud crash, through the wall. None of the occupants were injured, further than being deafened for a short

THE additions to the Zoological Society's Gardens during the THE additions to the Zoological Society's Gardens during the Advances in Knowledge and Teaching due to Experimental past week include a Banded Ichnoumon (Herrester fascialus) Method.—These changes have occurred both in the profession NO. 1136, VOL. 44]

from West Africa, presented by Dr. Arthur Williams; a Black Stork (Ciconia nigra), European, presented by Lord Lilford, F Z S.; two Nilotic Crocodiles (Crocodilus vulgarii) from Africa, presented by Dr. Lester; two Black Storks (Ciconia mgra), European, two King Parrakeets (Aprosmictus scapulatus) from New South Wales, purchased, a Laughing Kingfisher (Dacelo gigantea) from Australia, deposited.

OUR ASTRONOMICAL COLUMN.

RESEARCHES ON THE MEAN DENSITY OF THE EARTH -The Monthly Notices of the Royal Astronomical Society for June contain a brief account by Prof A Cornu of the experiments M Baille and himself have been making for some years to deter mine the mean density of the earth. The apparatus employed is fundamentally the same as that used by Cavendish. It consists of a horizontal aluminium rod, suspended by a torsion thread 4 metres long, carrying at each end a ball of copper, bismuth, iron, or platinum, and at its centre a vertical mirror reflecting the divisions on a millimetre scale 5 metres away Two globes of mercury are used to produce the torsion couple. The displacements of the seale-divisions are observed with a telescope, I wo globes placements of the seale-divisions are observed with a telescope, and indicate the angular displacements of the rod. The chief suprovements which have been made upon the appurises used to approximate the support of the control of th quickly filled with mercury has been advantageously substituted for the movable lead weights (3) The complete oscillation of the halance arm is registered on a chronograph by observing and recording the transits of the reflected scale divisions (4) The use of an annealed glass fibre to eliminate errors due to dis placements of the zero point (5) The screening from variations placements of the zero point (5) The screening from variations of electric potential by putting all parts of the apparatus in metallic connection with the earth (6) The copper case protecting the balance arm is a good conductor of heat, and of sufficient thickness to eliminate the disturbances due to variations in temperature. The authors hope soon to obtain an estimation of the prohable error of their measures, and to arrive at a definite result for the constant they are determining.

PARALLAY OF P URS 4 MAJORIS -- Vol xxxviii of the "Astronomical Observations of the University Observatory of Konigsberg" contains the heliometer observations of P Urse Konigsberg" contains the heliometer observations of P Ursæ Majoris (Arg. Octizen 11677) made by Dr. Julius Franz, from which he deduces the parallax o" 1002 ± 0" 0065, or approximately 0" 10 ± 0" 01

THE PROGRESS OF MEDICINE.

THE Bournemouth meeting of the British Medical Association has been a great saccess, and a great deal of useful work and discussion has been recorded. Among the addresses we may refer to the President's (Dr. J. R. Thomson), on the present position of medical officers of health, of Dr. Lauder Brunton, on twenty-five years of medical progress; of Dr. J Chiene, on rest as a therapeutic agent in surgery, and others on lunacy legislation, the uses and prospects of pathology, &c We make the following extracts from Dr. Brunton's address,

which presents us with a most admirable and masterly analysts of recent progress -

... Perhaps there is no period in the whole history of medicine in which such rapid changes have taken place as in the last five-and-twenty years. It is impossible to give anything like a complete account of these in the brief space of one hour, and I compute account or trees in the brief space of one hour, and I shall therefore retariet myself to a few of the more prominent points, and especially those that have come directly under my personal cognisance; for, like the man who made one-half of his fortness by attending to his own staffars and the other half by leaving other people's alone. I may probably unlike the time at my disposal best by speaking of what I know myself and leaving other things own.

itself and also to some extent—in this country at least—in the education and training of the men who enter it. We notice, education and training of the men who enter it. We notice, first, that a very great increase has occurred in the knowledge of the nature, causation, and treatment of diseases possessed the profession as a whole, but perhaps a still greater gain is the general adoption of the experimental method by which most of our recent knowledge has been acquired, and from which we may hope for even greater advantages in the future. In correspondence with the acquirement of knowledge, we notice also a spondence with the acquirement of knowledge, we notice also a great alteration in the teaching of medicine, and especially prominent is the tendency to make such teaching practical instead of theoretical by training men to place their dependence upon objective facts, and not to receive without experimental data the theories or speculations of any master, however great - he may be. .

Direction of Advance —The greatest advance made in the last twenty-five years has been in the direction of the accumulation, co ordination, and teaching of facts instead of theories, of the phenomena of Nature as opposed to the fancies of the human mind.

Co ordination of Facts -But the mere accumulation of facts is of little use unless they can be so arranged, compared, and grouped as to bring them into relationship with some general law, and this we find in the world's history has been done from

iaw, and this we find in the world's nistory has oeen cone from time to time by some master-more, but in its principles and practice, is really a subdivision of biology, and this, like all practice, is really a subdivision of biology, and this, like all other branches of knowledge, has been most profoundly modified by the general acceptance of Darwin's great thoughts—the doctring of evolution, the strungle for existence, and the survival Wherever we turn we find that Darwin's influence of the fittest has modified the direction of thought, and whether the study concerns the evolution of the elements, the evolution of the plane-ary systems, of living beings, of communities, of customs, of laws, ary systems, of living beings, of communities, of customs, of laws, of literature, science, or art, in every department of human know-ledge we find that men, consciously or unconsciously, are influenced by Darwin's work. It is with shame I confess that five and twenty years ago, although I had taken a University degree not only in years ago, although I had taken a University degree not only in medicine but in scence, and might therefore be supposed to be of his "Origin of Species," and I first heard its name in Vienna from the lips of an Austrana who was speaking of it in terms of the highest praise. "Visht is 17" I asked, and my question the highest praise "Visht is 17" I asked, and my question it causes myself now, when the possibility of sixth giperance seems to me, as it must to you, almost increable, and yet such was the fast. The publication of Dawran's "Origin of Species," in 1859, has done more to change the current of human thought than anything else for centuries, but while its influence is every-where felt, biology and all its subdivisions have been more especially affected

Changes in Medical Students - But great as the changes have been during the last five and twenty years in the profession itself, they are perhaps quite as great in the men who enter

Long ago the ductor's means of diagnosis consisted in inspecting the tongue, feeling the skin, counting the pulse, shaking the urine, and looking at the motions and the sputum. But now, in urne, and looking at the motions and the spatium. But now, in addition to a through training in ausualitation and percession, students have to learn the use of the laryngoscope, ophthalmoscope, and obscope, and obscope, and obscope, and obscope, and obscope, and the application of electricity. They have to acquire a knowledge of the chemistry of the urne and its alterations in disease, and, what takes still more tune, they have to learn the microscopical appearances, not only of the tissues and excretions in health, but their alterations in disease, and must be acquainted with the methods of staming so as to

and must be acquanted with the methods of staming so as to detect tuberle boalin and other disease germs. Dispariments of Greatest Advance—Fire and wenty years Dispariments of Greatest Advance—Fire and wenty years ago we knew only too well that typism was indections, and that premis and expupelss were likely to spread in a ward when these descens as we do now, not had we the same means at our disposal wherewith to combat them. The departments in which the greatest advances have been made within the last five-and-twenty years are in those of fevers and diseases of the nervous system. A new ers in the study of the latter was forestandowed by the appriments of French and Hitage in the busin of the collisions of the cortical centres, both motor and sensory, in the greatest advances have 6een mode within the last five-analy of the Spaniards of the Cordilleras. Their cupidity of the merions to entirely sense are in those of fevers and diseases of the nerrous to the control of the sense of the sens

that of man for experiments upon it to be of much practical use in the diagnosis of human ailments, while the likeness in the brain of the monkey to that of man at once allowed conclusions drawn from the experiments upon the former to be transferred upon the latter Vet if we try to describe in one word the dedrawn from the experiments upon the tormer to oe transærrea upon the latter. Yet if we try to describe in one word the de-partment in which medicane has made the greatest progress within the last quarter of a century, that word must be "fevers", for during this time we have learned to recognize fever by the use of the thermometer in a way we never did before, we have learned the dependence of the febrile process in the great majority of cases upon the presence of microbes in the organism, and we have become acquainted with an immente number of chemical substances which have the power both to

numer of chemical substances which have the power out of destroy the microbes and to regulate the febrile process.
**Introduction of the Thermonictes —It is true that the thermonecter was used by Danelssen, in leprosy, before the year 1848, and its more general use began with Wunderlich's observations nearly thirty years ago, but it is only within the last five-and twenty years that its use has become at all

Nature of Fever —The thermometer has not only enabled us to detect the onset and to watch the progress of fever, but in to detect the onset and to watch the progress of fever, but in conjunction with microscopical research, physiological experi-ment, and chemical analysis it has enabled us to gain a fulfer know that during it the organism is consuming raidyly, or, as Dr. Dorald MacAhster graphically says, it is like "a candle buring at both ends," and we have learned scientifically the reasons for the practical treatment, of which Graves was to proud that he witce as has own egipth, "It led fevers." We have learned also, to a great extent, the necessity for the elimina-tion of the waste products, or ashes as we may term them, which the excessive combustion produces, and thus we know why the surgeon is so anxious regarding the result of an operation when the kidneys of his patient are inadequate. For if any febrile attack following the operation should lead to increased demands upon these secreting powers, they might fail to meet it, and the retained exciets would potson

the patient
New Methods — The rapid increase in our knowledge has
been due not merely to the constant use of old methods, but seen oue not nerely to the constant use of oid methods, but to the introduction of new ones, and more especially to the general recognition of the fact that the same strategy which has other proved so successful in war is to be applied in attacking complex problems. They are to be separated as far a possible into their several components, and each of these is to be overinto their several components, and each of these is to be over-come in detail. As presented to us by observation at the bed-come in detail. As presented to us by observation at the bed-and we are only succeeding in doing it by examining the various factors one by one in the laboratory. The greatly in-creased powers of the microscope and the better methods of illumination have been of the greatest service, but their shifty illumination have been of the greatest service, but their shifty would be very much less than it is had it not been for the general introduction of the microtome and the invention of new inethods of staining When I was a student the microtome was only used for cutting sections of wood in the class of practical botany. About that time it was employed by Mr. Stirling, botany. About this time it was employed by Mr. Strings, Porf Cooder's seastant, in the preparation of sinnel insuer. For Cooder's essantant, the preparation of sinnel insuer. Rutherford The facility with which sections are made by it has nade microcopepair research much less teclious, and has embled trained histologists to do more work in a given time, which is the contract of the more than the contract of the more than the contract of the microbe which are so important in the crocognies most of the microbe which are so important in the causation of disease

Good Out of Evil.—It is very interesting to see how good may come out of evil, and a striking illustration of this is afforded by the history of medicine in the period we are now another by the interpol mental that we can trace a great part of our knowledge of disease germs and of the antiesptic remedies we use in treatment to the cupidity and stupidity of the Spannards of the Cordilleras. Their cupidity led them

would make his fortune. Amongst others, Perkins tried to do this, and, although he failed, yet in the attempt he discovered this, and, althougn ne tailed, yet in the attempt ne uncovered the anilin dyes, whose staining powers have not only helped us so much in ordinary histological research, but have made it possible to distinguish disease germs which without them would have been invisible. But the discovery of the anilin colours was only one outcome of the attempt to make quinine syntheticompounds has led to the production of salicylic acid and acetanisde, antipyrin, phenacetin, and all the other antipyretic remedies whose number is probably legton, and whose names already have become so numerous as to be troublesome. Here we see good has arisen out of evil, for if the pince of quinine had not been so high, the researches which have proved so useful

might not have been begun even yet

Small and Great, Foolish and Wise — In looking at another of the greatest advances which medicine has made-namely, the ledge of infective disease—we can see how enormous re nations may be consequent upon a research which many men would have termed useless or even frivolons. I can hardly fancy any better illustration of St. Paul's observation about the foolish things of this world confounding the wise than Pasteur's researches on tartaric acid, for what could seem Pasteur's researches on lartaric and, for what could seem more foolish to the so called practical man than the question, "Why does a crystal of tartaric and sometimes take one shape and sometimes another?" Wet from an attempt to answer this question has arrien the whole of Pasteur's work on fermentation in general, and on that of winc, beer, and vinegar in particular, whereby he has been able to save millions. to his country by accelerating the production of vinegar and pre-venting the souring of wine and heer. His observation that venting the votting of wine and heer. His observation that its rate and commitment turned the ray of polarization to the right, sometimes to the left, that, indeed, there were two could be combined to the control of the result dextro tartaric acid, and leaves the leevo-tartaric acid behind This led him to investigate such minute organisms, and, by simplifying the soil in which they grew, and separating the organisms one from another, he learned the conditions of their growth, and showed that most processes of fermentation were due to the presence of living organisms. It is true that while Pasteur was still a boy at school, Peyen and Persoz had shown that the liquefaction of starch and its conversion into sugar was due to diastase, and that Dumas in a report on a paper by Guérin-Varry had pointed out that, although unlike diastase, the active principle of the gastric juice had not been isolated, it was probably a ferment of a somewhat similar kind. Dumas classed yeast as a ferment along with diastase, and the fact that such a process as conversion of starch into sugar could be effected without a living organism naturally rendered it all the more difficult for Pasteur to prove his thesis that most fermentations were due to living organisms.

were due to living organisms.

**Chemical and Bislogical Freurs of Fermentation — The two
views of the action of ferments—namely, the chemical and the
biological—may, I think, fitly be likened to Pastur's two kinds
of tartanc acid, each by itself being lopsided and incomplete,
forming a symmetrical whole only when united. There can be
no doubt of the truth of the chemical view that dissistees not at no coup or the run of the enement view that masks is not a living organism and yet convents starch into sugar. There can through the run of organisms which cause fermentation are living bodies, and that without the presence of these living bodies alcoholic, acetic, and other forms of fermentation would not exist. Metrobet and Euspines. But recently we have come to gre-

cognize that these living organisms may produce their effect by manufacturing chemical ferments, and that these ferments may occasionally do the work, although the organisms which may occasionally do the work, atmough the organisms waiter form them may be absent. It is quite true that it is difficult —perhaps impossible—to get fermentation from the dead yeast plant, but we may find a parallel for this in the fact that the pancreas of the higher animals sometimes yields an active ferment and sometimes not. Nor need we wonder that active rements produced by microbes have but a slight action com-pared with those of the microbes themselves, if we remember how very little power of digestion a dead pig's stomach has as compared with the amount which can be digested not by the live animal itself only, but by the herds of swine consisting of its "fathers and mothers, its brothers and sisters, its cousins and during all the term of their natural lives , for in the process of fermentation microles are growing, fermenting, and process of fermentation microbes are growing, fermenting, and dying with great rapidity, and many generations occur in a fermenting fluid in the space of a few hours, so that the total effect they produce will be out of all proportion to any which can be got from the microbes themselves at a single instant.

Microbes and Disease -- From organisms as a cause of fer-mentation and of the diseases of wine and beer. Pasteur went on to investigate their action as causes of disease in living beings

on to investigate their action as causes of divease in living beings—first in the silkworm, near in the lover animals, and, lastly, in man. It established the dependence of the silkworm disease and of animars upon the presence of specific microthes which distributes the silkworm disease and restored the silk should be silkworm to read extension and restored the silk should be silkworm to read the silkworm of Distant Germi — Flux while this survestigation is interesting to us as illustrating the probable cause of the disappearance of typhus fever, to which I have already alluded, Patseirt's researches on anithrax are still more important as Pasteury researches on antirox are still more important as bearing upon the question of protective inoculation; for he bearing upon the question of protective inoculation; for he body and grown in flasks under varying conditions, some of which were favourable and others unfavorable to its growth High temperature enfeebled the wrus, so that it no longer killed an animal with the same certainty, and by involuting first with a weak virus and then with one successively stronger and stronger, he found that animals could be completely protected either fi inoculation by the strongest virus or by infection from other

animals suffering from the actus disease

Increase in Vivulence of Disease Germs —Another extraordinary fact which he made out was that the virus thus weakordinary fact which he made out was that the virus thus weak-ned, so that it will not kill a guinea-pig a jear old, and still less a sheep or ox, may again be rendered most potent by inoculting the property of the property of the property of the property of this older and stronger guines pig's, the strength of the disease garms, increasing with every inoculation, until finally sheep and cows may be killed by it. We can thus yee how an epidemic of disease beginning sporadically, and attacking weak individuals may gradually acquire such strength as to attack and carry of

the strongest

the strongest Pont Chilines: —Pasteur's plan of growing disease germs out-side the body in broth, although of the utmost value, did not allow a convenent esperation of different germs, but this can now readily be done by Koch's plan of sowing them, not in a bround medium, hat on solid gelatine spread on glass plates, so that the growth of the germs can be daily watched under the microscope, and inoculations made from single colonies on other plates until pure cultures have been obtained. By thus isolating piaces until pure cultures have been obtained. By thus solviting the different microbes, we learn their life history, the mode in which their growth is influenced by differences of soil, of temperature, of moissure, by the addition of various substances which either favour or retard their growth, and, last but not least the effect which pre-success the substances when the substances where the substances when the substances when the substances where the substance least, the effect which one microhe has upon another when they are grown together at the same time

Struggle for Existence amongst Microbes -For even among these minute organisms the struggle for existence and the survival of the fittest exists, like that which Darwin pointed out

so clearly in the case of higher plants and animals

Struggle for Existence between Microbes and the Organism — But it is not merely hetween different species of microbes or different cells in an organism that this struggle occurs. or otherent certs in an organism that this studge occurs. It takes place also between the disease germs and the cells of the organism which they invade, and the result of the struggle may be determined, not by some powerful sgency which weakens or destroys either the organism or the mi crobe, but by some little thing which simply inclines the scale in favour of one or the other. Thus, in the potato disease, the victory of the invading microbe and the destruc-tion of the potato, or the death of the microbe and the health of the tuber, may depend upon some condition of moisture or possibly of electrical change in the atmosphere which aids the growth of the microbe disproportionately to that of the potato.

These almospheric conditions need not necessarily be antagonistic suces amongoneric conditions nect not necessarily or amongonistic to the potato, they may even in themselves be advantageous to n, but if they help the microbe more than the plant, the microbe will gain the victory and the plant he destroyed Fight between Cells in Higher Organisms—The fight between

the organs which Æsop describes in his fables actually occurs between the cells in some vertebrate animals, and the schism predicted by St. Paul as the result of such a fight actually takes place For in the tadpole, at one stage of its existence some of the cells at the base of the tail begin to eat up others, with the result that schism occurs and the tail falls off

result that schism occurs and the tail sails of Phagey-toris.—This struggle for existence between the cells of an organism and microbes has been beautifully shown by Metschnikoff in the Dapline or water flea, where the process of the cells cating up the microbes or the microbes destroying of the cells eating up the microbes of the microbes destroying the cells can be actually observed under the microscope. This process of phagocytosis is now regarded by many as only a small part of the struggle between an organism and a microbe, but it is impossible to see one part of a microbe half diageted by the cell in which it is embedded, while the part outside remains unaltered, without believing that the process is one of great miprofuse. At the same time, it seems that the process of phagocytosis, where the microbe and the cells meet in close conflict, bears about the same relationship to the total struggle that a bayonet charge bears to a modern battle. The main part of the fight is really carried on at some distance by deadly weapons—by bullets in the case of the soldier, and by ferments, poisonous albumoses, and alkaloids on the part of the cells and the microbes. In some of Metschnikoffs observations we can almost see this process, for he has figured leucocytes dead, and apparently burst by the action of conidia, lying close to but yet outside them, as if these conidia, I ke the dragons of fable, had spit out some venom which had destroyed them

Venom of Murobes .- Within the last few years attention has been gradually becoming directed less to microscopical ex-amination of the microbes themselves and more to chemical investigation of the ferments and poisons which they produce; investigation of the ferments and possons which they produce; yet, strangely council, the very moment when chemistry is written to the contract of the contrac

microbes are nearly allied, chemically and physiologically, to those formed in the slimentary canal of the higher animals by digestive ferments, it is natural to suppose that microbes, like the higher animals, split up proteids, starches, and sugars by enzymes, which they secrete, and which in both cases may be enzymes, which they secrete, and which in both cases may be obtained apart from the living organisms which produce them, that, in fact, we should be able to isolate from microbes bothes which correspond to pepsin or tryptin, just as we can stolate these from the stometh or pancreas of an animal. In some, although not in all cases, this attempt has succeeded. *

Processor Allumous** — The allumous produced by microbes

resemble those formed during normal digestion in being poisonous when injected directly into the circulation, although they msy not be so greatly absorbed from the intestinal canal. One of the most remarkable discoveries in regard to albuminous bodies is the fact that some of them which are perfectly innocuous, and, indeed, probably advantageous to the organism in their own place, become most deadly poisons when they get out of own place, becules most deathy poisons when they get out of it. Thus, the thyroid and thymus glands, which are perfectly harmless and probably useful, were found by Wooldradge, when broken up in water, to yield a proteid which instantaneously coagulated the blood if injected into a vein, so that the animal died as if struck by lightning; while Schmidt Muhlheim, under Ludwig's direction, found that peptones had an exactly opposite effect, and prevented coagulation altogether

effect, and prevented congulation slogether.

Naturalization of Fluoreau Allementer—Perhaps the analogy is too vague, but we seem to find here sometiming very lake pratectar ive obtained furnation and con counting polarized light pratectar in the state of the state

"I Vide Brunton and Macfayden, Crooman Lectures on "Chemical Struc-ture and Physiological Action," British Medical Journal, June 15, 1889, p. 1376.

sither one or other alone might be a deadly poison. The albumoses formed by microbes appear frequently, if not alway, animals. Pasteur's treatment of hydrophoba is based on the idea that the spinal cord of rabid animals contains a virus, and that student—Koch's tuberculio—may be sumiar in this respect,

at antidote—Koch's tuberculin—may be similar in this respect, and may yet, by suitable discrazione, fulfil the hopes of its able and single numbed discovere—Perhaps a similar process of splitting up and recombination may explain the formation and disappearance of the ensymes, such as pepara not trypting by which digestion at carried on The pancers of a fasting animal will not digest albuminous bodies like fivine, while the pancers of an animal killed drum; full digestion will do or mother substance, which yields the digestive ferment, and, as Kuhne has shown, by treating it first with acid and then as Kilme has shows, by tresting it first with acid and then with alkali, it becomes active. Again, to reser to the analogy of Patters's tarrant acid, we seem to find that the inactive, and the process of the state of the process of the process of the process of dispetsion in life, and yields the lopsided and active panceaute ferment But, if this be so, what because the process of the process o destroy sugar.

destroy sugar.

Immunity —We must be very careful in our speculations, and test them by experiment, but such observations as these may tend to throw some light upon the nature of immunity may tend to throw some light upon the nature of immunity immunity is probably a very complex condition, and is not dependent allogether upon any single factor, but we can now understand that if a microbe has guined an entrance into an organism, and produces a proteid or an albumo-e postenous to the organism which it enterer, it may grow, three, and destroy that organism, while the injection of some other proteid which would neutrilize the posion might save the admini

seed which would neutralize the poison might save the animal while the mercobe would perilamkin has found that, while a mouse inoculated with anthrax will die within twenty-four hours, a rat resists the poison altogether; but if the mouse fire being inoculated with the disease has a few drops of rat's serum injected into it, instead of dying, as it would otherwise certainly do, it survives just like the rat, and from the spleen of the rat Hankin has isolated a proteid which has a

Similar protective action to that of the serum

Cure for Tubercle.—Working on similar lines, Bernheim and Cut for Island A. Working on similar lines, Bernheim and Lepine used the injection of goal's blood in phihiss so as to stop, if possible, the progress of tubercle, and Richet his used the serum of dog's blood, for the goat is quite immune, and the dog is to a great extent, though not entirely, immune from attacks of tuberculous. The injection of goal's blood in somewhat large quantities has been given up, while dog's and goat's serum in small quantities of 15 to 20 minus.

dog's and goat's scrum in small quantities of 15 to 20 minims at intervals of several days a still under trial

Action of Blister:—But if immunity can be insured by such alight changes in the organism as a few drops of serum from a rat will produce in the body of a mouse, it is natural to suppose that a similar change might possibly be effected by removing the albuminous substance from one part of the body, and introducing it, perhaps after it has undergone slight change, into another. As I have already mentioned, the change, into another. As I have already mentioned, the albumness of ordinary digention are positioned when they are injected into the circulation, and as are the proteed substances obtained from the thyroid and thymus glands. Why, then may not the seram of one's own blood, withdrawn from the vessels by a billier and reabsorbed again, not be as good as the serum obtained from the blood of an animal?

Bleeding .- It is quite possible, too, that the good effects of

Bliefang.—It is quite possible, too, that the good effects of beeding may be due to a maintar cush name holy is a most complex pucces of mechanism. We learn its action bit by its good to the complex pucces of mechanism. We learn its action bit by its good to good to good the little piece which attracts attention at the moment as all-important to the moment of the complex pucces of the piece which attracts attention at the moment as all-important to the complex pucces of the piece which attracts attention at the moment as all-important to the complex pucces. The piece which attracts attention at the moment only for the team tendency manifests steelf in the pursuit of knowledge of all kinds, yet its me medicine more specially that this tendency comes to

be a matter of life or death, for upon the medical view prevailing at the moment medical princice is agit to depend, and erroneous views may lead to the death of many patients. So ong as practice depends upon theories, unchecked by expericertain, and dangerous. One of the greatest guns of the last five-and-westly years is the general introducion of the experimental method, and the labolt which has been growing up method data. Specialtons such as those in which I have been indulging in regard to binsters and bilood-letting are useful as indicating lines of experimental research, but until data. Specialtons such as those in which I have been indulging in regard to binsters and bilood-letting are useful as indicating lines of experimental research, but until data. Specialtons such of the prefer the providege is almost sure to lead to one-sided practice, and thus, diverging further and further from the truth, each at last in flatheood and and further from the truth, each at last in flatheood and

"Metapota.—Perhaps no better example of this can be found than antaspice surgery, from the time of the good Samantan down to Ambrouse Paris and Str Joseph Lutter. The good Samantan bound up the wounds of the goot traveller, pour-based of the poot traveller, pour-based of the poot traveller, pour-based paris of the poot traveller, pour-based paris of the metapota paris, when his outments ran out, could not sleep for thinking of the muserable soldiers to whom they had not been brouse Pare, when his outments ran out, could not sleep for thinking of the muserable soldiers to whom they had not been than the properties of the properties. The properties of the properties of the properties of the properties of the properties. The properties of the

Distription — But it is not only in surgery that recognition of diseased germs as a source of danger to the organism has led to their destruction outside the body, and insured safety from their attack. This occur in all infective diseases, and this term now includes many which were no formerly regarded as such, for nather consumption not pneumonus was formerly to the safety of the safety of

and offly interest, on the second of second of the second of the causes of spidermic diseases, hey were utterly unable to combat them, and they either in lary slew defencelrs people for posoning the wells, as in the Middle Ages, or appointed days of fisting and prayer, as in our own times. But note an epidermic is known to depend upon the presence of a ceriain organism, precention can be taken for destroying the lessening the usetypibility of the organism to its ravges made the body by inoculation, or combating its effects by means of antipyratics. A knowledge of the life-history of merobes has embled us to sacertain the power of different substances, there to destroy them completely or to serve to restend their venue of the diseases which these microbes might otherwise

Gains by Experiment an dissimil.—It is said that our months are full of promuse, but our having are empty of results. The server to this is, that anyone who doubts the utility of experiments of the control of the con

helped towards its general acceptance in this country.

Future of **Paramenelogy*—Bits perhaps the most promising thing about pharmacology is that we are now just beginning thing about pharmacology is that we are now just beginning thing about pharmacology is that we are now just beginning as a state of the physiological action that we can, to a certain extent, predict the action of a drug from its chemical structure, and are able to produce new chemical compounds thaving a separative distribution of the production of the action of the production of the action of the print of giving to each one the precise action which would make it most suitable in any particular case, we may be able, from noticing one of its actions, to infer that it possesses others. We are, indeed, giving a knowledge of the action of drugs both of known and unknown chemical structure of the production of the production of the action of drugs both of known and unknown chemical structure.

THE INSTITUTION OF MECHANICAL

THE summer meeting of the Institution of Mechanical Engineers was held at Luverpool last week, commencing on Tuesday, the 28th uit, and concluding on Freday, the 18th uit, and concluding on Freday, the 18th uit, and concluding on Freday the 18th uit and the 18th uit of the 18th uit of the 18th uit of 18th The sittings were held in the concert-room of St. George's Hall, and the following list of papers was on the agenda: review of marine engineering during the past decade, by Alfred Blechynden, of Barrow-in-Furness, description of the ware Bleshynden, of Bairow-in-Furness, deserption of the ware-house and machinery for the storings and trained of gain at the house and machinery for the storings and trained of gain at the on the experimental engine and the alternative testing machine in the Walker Engineering Laboratories of University College, Liverpool, by Frof. H., 5 Hole Shaw, of Liverpool; on the Liverpool, by Frof. H., 5 Hole Shaw, of Liverpool; or the Manchester Ship Canal, by Jr. Leuder Williams. Engineer-in-Chief to the Canal Company. There was also a paper on the Liverpool water-worsh, but this was adjourned to the next

The Institution having been welcomed to Liverpool by the Mayor, Mt. J B Morgan, and the formal lastiness having been transacted, Mr. Blechynden's priper was read. Mr. Blechynden and the St. Detector, Bramwell. has taken up the work commenced by bu Frederick Bramwell at the Liverpool meeting of 1872, when the latter presented an historical paper giving a review of manne engineering up to that time. In 1881, the lastitution met at Newcasile, when Mr. F. time. In 1881, the festitation and at Newcoth, who Mr F C, Marshall, will known Tymesule organeer, real a paper which consisted of a retro-pect of the name years since Sis Prederick Brannelly's paper had been send. We now have Mr Blechyndan cariying on the work. These periodical is eval war are instactive. Here cannel the eageneet to take stock of the transpect of the stock of pressures averaged 77'45 pounds per square inch, the average piston speed was 467 feet per minute, and the heating surface per indicated horse-power was 3 99 square feet The consumption of coal per indicated horse-power was 1 828 pounds per hour As a contrast to this, Mr Blechynden tells us that at the present time the three stage expansion engine has become the rule, and the bottle pressure has been mersased to 160 pounds, and even as high as 200 pounds per square under Four-stage expansion engines of various forms have also been adopted. Forced draught has come to the front-stage expansion expansion been adopted. Forced draught has come to the front-stage of the found to time the three stage expansion engine has become the rule, that we do not always place full reliance in the details green with regard to fise economy in connection with mercastile with regard to fise economy in connection with mercastile the best performance of the engines, so that they are credited with a duty they cannot maniant commonuly throughout a voyage. Probably, however, the figures green by the author are accitated for comparative purposes, and they are not, as are accitated for comparative purposes, and they are not, as are to be true. We would here draw attention to the author's to be true. We would here draw attention to the author's expression "three-stage" and "for stage" compound engines. Engineers have been in the habit of referring to these types as a construction of the control of the Engineer have been in the habit of referring to these types is triple expansion and quadruple expansion engines. This no-cylinder compound, and even the simple non-compound engine expands the steam more than three or four times. Some engi-neers, recogning this, have used the terms "triple compound," or "quadr uple compound," but Mr. Blechynden's expression has

the merit of greater accuracy and simplicity. We hope that enthe merit of greater accuracy and simplicity. We hope that en-gineers, who are gut to be romewhat loose in the naming of objects, will adopt Mr. Blechynden's terms. Added to the paper are escalater seasons or the present day. A long discussion of followed the reading of this paper. It turned chiefly apon the question of forced draughly, corrugated flows, and the rules with regard to bolier testing which Mr. Sennett introduced when he was at the Admirally. With regard to the forced draughly question, the boiler testing with regard to the forced draught question, the very sensible opinion seemed to have been arrived at that forced draught, though a good thing in itself, may prove a great ill if overdone. It is in the Navy chiefly that forced draught though that a located draught that the second of the second o if overdone. It is in the Navy energy that forced draught has gained an evil reputation, and naval officers are largely to blame for this, although the engineers must take their share of the responsibility. When it was found how great an accession of power could be obtained by forcing combustion with a of power could be obtained by forcing combustion with a fan, naval officers thought they had a royal road to speed. Bollers which had been designed on principles that had grown up under a simple chimney draught rigitum, were triged by familiate to duties beyond their powers of endurance, and then, when tube plates buckled and tubes leaked, forced draught was said by gellant admirals to be "the invention of the Evil One." sad by gollant admirals to be "the invention of the Erd One."
the engineers, as we have said, were also to blaime. The
boiler liss always been the lahmad of the machinery
engine. As a consequence boiler construction has been a
matter of rule of themb, and, when the engineral railes upon
which it was based have no longer applied, the engineer has
matter of rule of themb, and, when the engineer list a
matter of rule of themb. The top of the the late of the
upon which to build new. The top pedo heat builders have no
trouble with forced draught, though they blow far harder than
torouble with forced draught, though they blow far harder than
good engineers—not mere blind followers of "practice"—
as was proved by the papier read alta tyrange on this valued

a remark on the subject which might have increased mere and
a remark on the subject which might have increased mere a remark on the subject which might have received more a remark on the sanged which might have received more attention. It has long been claimed by the makers of this type of furnace that additional heating surface, and that of a most valuable kind, was obtained by the corrugations. This Mr. Gray said was a fallacy, for the heat from the furnace proceeded viay said was a fallacy, for the heat from the furnace proceeded only in radial lines, and therefore no greater effective area of heating surface could be obtained than that due to a plain cylinder

Mi Shapton's paper was an interesting description of the hulding and machinery referred to in the title, by which giain is trunsposited and stored. The warehouse in question consists this fly of a wax cellular structure which might be described as a brick and mortar honeycomb, filled with grain be described as a price, and morrar noneycomo, mace wang grain plate of honey. There are 250 heagonal bins or sites, each measuring 12 fect across the angles and 80 feet deep. The storage capacity is 2,240,000 bushels. The grain is lifted from vessels by elevators, and carned to the top of the building, from seesch by elevators, and carned to the top of the building, from shonce sertical movement was published by gravity. Horizontal trace is carried on by commons moving licht or bands which trace is carried on by commons moving licht or bands which had been seen to the seed of the description of the seen of the description of the seed of the description of the seed of the description of the seed of the the story action was in the country, the bins are made wholly of wood, but this is subject to rot, and harbours weevils. Sheet-iron rusts and birck retains moisture, so that with brick the grain heats unless well looked after and ventilated. On the whole, however, brick has the preference in this country. Sir James nowever, price has the preservice in this country. Sir James Douglass made a suggestion which will, we should think, receive tation of the Eddystone Lighthouse at the Royal Naval Exhibition as a building not altogether dissimilar from a salo. It has very thin walls, which are constructed of espanded sheet steel, or the sheared lattice work, which forms the bond for a crust of Ports. sneared sature work, which comes the active and rigidity, and one which would not have the same defect as briokwork with regard to harbouring damp. The problem of ventilating grain is one of difficulty; and it may be said that it has not yet been solved. The most serious effort yet made was the building of a granary on the banks of the Thanes, known, we heliver, as the Patent vertilating Granary. This granary was referred to during the hydraulic department at Arnatrong's. The patent ventilating Granary arrangement consisted of a perforated their running down the centre of each bin. This was provided with a movable stop of page, and, by adjusting the height of the first he most part of the granary and the granary was pulled down after a time. It is easy to understand that move the granary was pulled down after a time. It is easy to understand that Granary has the granary was pulled down after a time. It is easy to understand that Gran mot hard times, into which he are would not penetrate me of difficulty; and it may be said that it has not yet been solved. form into hard lumps, into which the air would not penetrate

As a matter of fact it is found more advantageous to air the grain by giving it a constitutional over the carrying bands

Prof. Hele Shaw's paper on his experimental engine and

alternative centre testing machine was one of great interest. The engine in question, which is described as a marine engine, though it has a large fly wheel, is, we believe, the most elaborate from an experimental point of view, yet made. The question has been raised whether it is not too elaborate, so that satisfactory results will not be reached on any one point. That is a problem which remains to be proved by facts, for the engine has only just been erected. It is 150 horsepower, and is of the ordinary vertical three-cylinder three-stage power, and is of the ordinary vertical three-cylinder three-stage compound type. The high pressure and intermediate cylinders have cylindrical valves, and the low pressure has a flat motion—namely, ordinary Stepheron lah, motion, for gear, and Hackworth gear. The cylinders are packeted at side and ends, and there are provious in the way of con-nections for working in every possible manner, i.e. cylinders all packeted, not packeted at all, or any out or tocylinders all jacketed, not jacketed at all, or any one or two picketed. Any combination of cylinders can be worked, or any one cylinder alone. In addition to this the cranks are adjustable on their shaft, so that any combination semicons that are at command would require years to work through. There are the usual measuring tanks and other apparatus for quantita-tive tests. An excellent suggestion was made by Frod Good-anna during the discussion. He proposed that arrangements should be made for testing the students knowledge by patting the rigge entry of the control of the control of the control of the through the control of the control of the control of the control of the through the control of the through the control of the control of the control of the control of the through the control of the contro nne engine into constitions not in accordance with proper design For instance, he would have valve rods or excentir rols of improper length, valves ill-set with improper lap or leaf, leaky valves and photons, and various other ills, to which engines are subject, purposely introduced He would also provide a means of passing water into the cylinders. He would then have this student take diagrams from the engine, and leave him to determine the cause of the defect by the appearance of the cards We hope Prof Goodman will be able to follow up this useful suggestion in his own laboratory at Leeds The alternative testing machine is a 100-ton single-lever machine of the Wicksteed type. The alteration in power is got by substi-tuting one julcium for another a few inches distant. The sanism by which this is done is ingenious, but the details

mecanarim by which this is done is ingenious, but the details would be difficill to explain without the aid of diagrams. The last paper read at the meeting was that of Mr. Leader Williams. The author commenced by saying that 464 million cubic yards had to be excavated in making the Mainchester Ship Canal, and as only 17,000 men and 200 horses have been used. there was evidently required a large power in the shape of there was evidently required a large power in the snape of mechanical appliances in order to get the work done in anything like reasonable time. Ninety seven steam excavators and eight steam dredgers of large power have been employed, and the spoil has in most cases been taken a distance of several miles. For this work, and for the general purposes of construction, 173 locomotives and 6300 trucks and waggons have been used. The railways laid for the purpose amount to 228 miles of single line. The rate of iant or the purpose amount to 225 mites of single line. The rate of execution has warred from three-quarters of a million to 1 million cube yards per month. There are also employed on the works 124 steem cranes, 129 nortable and other steam-engines, and 12 steam-pumps. The coal consumed by the engines is about 10,000 tons a month. These figures will give some idea of the heroic proportions upon which large constructive works. of the nerois proportions upon which raige constitutive was are carried out, and the capital required to start them. The whole plant of the Manchester Ship Canal has cost, we believe, close on a million sterling. The machines described in the

paper which were of greatest interest were the excavators. The chief of these is the now well-known "steam navvy," made by Ruston and Proctor, of Lincoln. It first came prominently into notice during the construction of the Albert Docks, and is looked on as a standard tool wherever large Docks, and is looked on as a standard fool wherever large excavating work is undertaken. It has the immense ad-vantage of being able to work in any kind of soil, even including sandstone rock, if not very hard. It is only in hard rock that blasting has to be done as an auxiliary The most interesting, or, perhaps, we should say the for the first time in connection with this work. These are on the same general principle as a floating ladder and bucket dredger of the common type. In place of the ladder and motive machinery being held by a floating bull, there is a small house mounted on wheels, and this runs on a line of rails on the summit of a bank. The ladder slopes outward from the side, summit of a bank. The tadder stopes outward from the side, reclining on the bank, which the buckets scrape away as they traverse, and deposit the spoil in waggons on the bank above. There are differences in detail between the French and German anere are distrements in detail between the French and German types, but in general principle they are allow The German machine appears to us the better designed, but Mr. Leader Williams says the French excavator is of more substantial construction. The weight of these machines is from 70 to 50 tons, and under favourable conditions they have been known to excavate the enormous bulk of 2400 cubic yards in one working day Mr Williams's paper was not discussed, which is a fact to be regretted by engineers, as the subject is one which requires ventilation, but time was running short After the usual votes of thanks, the sittings of the meeting were brought

We can only add a few words about the excursions On the Tuesday there was a lunch on hoard the big White Star liner the Majestic, for one section of the members, whilst others the Haystite, for one section of the memoers, whilst other-visited the grain warehouse, described by Mr. Shapton in his paper, and the new overhead railway, which has been designed by Mr. Greathead, the Engineer of the City and South London Railway, and which runs along the line of docks. This railway Railway, and which runs along the line of docks This railway is of steel and iron throughout, and possesses the novel ad so in seer and from infoughout, and possesses inc novel advantage of forming a water tight roof, under which the people of Liverpool will be able to walk on rainy days without getting wet In the evening there was a conversazione, which, of course, was the social feature of the meeting. On Wednesday afternoon the members visited the new engineering laboratories which have been added to University College, Liverpool, where the engine and testing machine described in Prof Hele-Shaw's paper were and testing machine described in Prof. Indee-Shaw's paper we examined. On I hursday one party visited the Mersey Docks, the Mersey Tunnel, and Laird Bros's hip yard and engine works the nersey tunner, and Laru Bros. Sup yard and engine works.
At the latter there are several interesting vessels in progress, including the big battle ship Noyal Oak, of 14,000 tons. Another
party went to Horwich, and saw the fine locomotive works which
have just been completed there by the Lancyshre and Yorkshire. have just been completed there by the Lank-value and Yorkshire Railway. These works have been beautifully planned and laid out under the superintendence of Mr. Aspinall. Although not so large as some other establishment of a similar kind, tury may be taken as a model of design. Mr. Aspinall. Although not so unique opportunity with a General of a similar kind, tury may accommissed experies on the model. Finally, the last day, was developed to the Mancheser Ship Canal, the members and extended the publishment of the members and extended the publishment of the source of the members that the members are some some some some some some that the members of the source of the source of the source that the source of the source of the source that the source of the source that the source of the source that the source the source that the source the source that the source the source the source that the source the source that the source the source the source that the source the source the source t being carried down the line of works in a special train, under the guidance of Mr. Leader Williams.

THE NEW GAS, CHLOROFLUORIDE OF PHOSPHORUS.

A S briefly announced in the report of the proceedings of the French Academy of Sciences, a note upon a new gaseous compound, containing phosphoray, fluoring, and chloime, has just been presented by M Mousain, on behalf of M Touless During the course of his work upon the fluorings of more of his work upon the fluorings of more was broad to the contract of the fluoring that the course of the cour prought in council with enfortne, the green colour of the latter at once disappeared, and there appeared to be formed a new and colourlets gas. The gas thus formed has been prepared in considerable quantity by M. Poulene, and its properties investigated. It appears to be directly formed by addition, according to the sample equationfor the trifluorate of phosphorus and chlorine are found to reach to a qual volumes, and the combination is attended by a contraction of one-half. The new gas may therefore be considered as phosphorus chlorofluorate, PCLFs, the chlorine derivative of phosphoryl and thiophosphoryl fluorate, PCFs and P.F. The most convenient mode of preparation is described as followed.

The court convenient mode of preparation is described as follow. Two flashes of equal expectly (thout 500 or 3 are taken, and filled respectively with phosphoras trifl sounds and allower they are connected together by a bent tube passing through the stoppers, and the flast containing the phosphoras triflatories are farther connected to the triple and the stoppers, and the flast containing the phosphoras triflatories to gradually displace at over into the chlorum. The two flasts being of equal capacity, it is evident that, when the whole of the triflatoride has thus been transferred, the reaction is completed, the green colour of the contents of the other flast disappears, and the remaining gas is almost pure chirocofiscioned in order to remove the last traces of chlorums, the gas is ready

for estimation.

Phosphorus chlorofluoride is a colouriess incombistible gas, possessing a powerfully urntung odour It is instantly absorbed and decomposed by water and by solution of alkaline or alkaline earthy hydrates A determination of alst supportunities and the solution of alkaline or alkaline earthy hydrates A determination of alst supportunities and the solution of alkaline or alkaline earthy hydrates A determination of alkaline or alkaline earthy hydrates and by supportunities and by the solution of alkaline pressures. It is dissocated at a temperature of 25°C into gaseous pentaficoride and solid pentachloride of phosphorus Phe induction sparse effects the same decomposition.

Sulphur reacts with phosphorus chloroflouride in a most insectuting manner. The reaction commences about the medium-

The induction spark effects the same decomposition. Sulphur reacts with phosphorus chlorofilourde in a most interesting manner. The reaction commences about the melting Sulphur reacts with phosphorus chlorofilourde and the melting and properly and the same of second thorophorphory florence, Esp., and here a most emphatic protest must be made against the manner in which many French chemist persistently genore the work of the war of the control of the co

and described as new by French author.

When phosphorus chloroflounde is passed over free phosphorus hested to 120°, it is decomposed with formation of phosphorus characteristics and the phosphorus characteristics and time when hested to about 180°, stated the gas with clead, and tim, when hested to about 180°, stated the gas with relating the phosphorus characteristics and time the phosphorus characteristics and the phosphorus characteristics and a chloride of the metal and guessou turbound of phosphorus. Hence, when purriying the gas from the last tuces of chlorine, creat, as agistiant burgs and to the perceptible amount of decom-

Water reacts in two stages with phosphorus chlorofluoride. When a little aqueous vapour is admitted into the vessel inclosing the gas, phosphoryl fluoride and hydrochloric acid are formed in accordance with the equation—

When passed into water, however, the gas is completely

1 Journ Chem Soc Irans, 1889, vol by p 305

NO. 1136, VOL. 44]

decomposed into phosphoric, hydrochloric, and hydrofluoric acids— PCl.F. + 4H.O = H.PO. + 2HCl + 3HF.

Ammonia gas reacts at the ordinary temperature with production of a white solid compound, readily soluble in water, which appears to be flaophosphamide, PF₈(NH₂),

hich appears to be flaophosphamide, $PF_3(NH_2)_2$, $PCl_2F_3 + 4NH_3 = PF_3(NH_2)_3 + 2NH_4Cl$,

Phosphoras chlorofluoride is absorbed by absolute alcohol with production of a compound possessing a penetrating odour, and which burns with a bright fluore bordered with green, and leaves a white residue of phosphoric acid. The nature of this compound has not wet been fully acceptanced.

a write residue of prosperors can't in a nature of this compound has not yet been fully ascertained.

These properties of phosphorus chlorofluoride indicate that the gas is much less suble than the pentalworlde, and that the two atoms of chlorine possess a mobility which renders their removal a matter of considerable each.

PROF MENDELEEFF ON THE VARIATION OF THE DENSITY OF WATER AT DIFFERENT TEMPERATURES.

THE Was Action of the District of the Xeenas Physical and Chemical Society (581). No 5) contains an amportant paper, by Prof. Mendeletelf, upon the variation of the density of water at different temperatures. In a work, published in 1884, and translated into English in the Journal of the Chemical Society, the Xussian Professor proposed the formula and the Xeenas and Tendesor proposed the formula to the person of liquids at a certain distance from the temperatures at which they change their state, and within the limits of accuracy attained in the present determinations. But he re-formula and he now proposed the formula.

$$S_t = 1 - \frac{(t-4)^2}{(A+t)(B-t)C'}$$

which embodies with misconserver, all that use the common about changes are set to expend the common about changes are set to the common about commo

from zero, and even superior to 100°. After confirming the above by a few example, Prof Mendelecti midactise the faint relations between his new formula for water and the general law of the expansion of liquids, by explaining the way in which he arrived at his new formula. It points out, moreover, that under the present state of the determinations of the density of water from the constant A, B, and C, in the above formula, and that provisionally, and especially for temperatures between 0° and 40°, they may be taken as follows —A = 947.0 Prof Mendelectff then goes on briefly to analyze the various corrections which ought to be taken into account in the deter-

Prof Mendeleeff then goes on breely to analyze the various corrections which ongly to be taken into account in the determinance, the expansion of solids, and the measurements of teamers, the expansion of solids, and the measurements of teamers, the expansion of solids, and the measurements of teamers are solid to the solid teamers are solid to the error of the best determinations of densities attains several the errors of the best determinations of densities attains several manage transcribed attempts at improving the current figures of densities by sutroducing into them several corrections, Prof. densities by support to the several corrections of the several corrections, Prof. densities by support to the several corrections, Pro

The averages of the volumes of water derived from the original

figures (Table I.), at temperatures from -5° to $+100^{\circ}$, taking the volume at 4° equal to 1,000,000, and the pressure being equal to one atmosphere, appear as followed, in the documen (V_s) of the subjoined table. They are followed, in the third column, by the volumes as calculated from Prof. Mendeleeff's new formula 1-

,	٧٨	V, = 1 S, catculated from the formula	dV dt for 1°	dV dp for 1 atmo sphere	Possible errors of the present deter- minations
- š	1 000 662	1 000 676	~ 157	- 52	∓ 29

In conclusion, Prof Mendeleeff repeats that he proposes as ties of water, because the former determinations were made on assumptions (permanency of the coefficient of the expansion of glass and mercury, and no notice being taken of pressure) which can no longer be maintained. If new measurements conglass and molecules which can no longer be maintained. If new measurements confirm the formula, or lead to a more correct one, we shall be better able to understand the laws of the expansion of all liquids, better able to understand the laws of the expansion of all liquids. and therefore of gases as well "In the case of water," he says, "we have begun to understand more clearly the influence of heat upon densities and volumes, and I believe that with the of the influence of heating upon matter"

UNIVERSITY AND EDUCATIONAL INTELLIGENCE

Oxford -The examiners in the Final Classical Schools

OVFORD—The examiners in the Final Classical Schools saved the Class List on Wedinerday week, completing the results of like examinations held in Trinity Term. The summer meeting of Extension students commenced on Firstay last, when Mr. Frederic Harrison, M.A. Wadham College, delivered the inaugural lecture. The propalanty of the movement is proved not only by the continual increase in the number of Students who avail themselves of the advantages. offered by this system of education, but by the interest which foreign Governments are taking in the development of the plan The French Government have sent two special commissioners to report on the prospects and condition of the University Extension movement, and a large number of the representatives of the American University Extensionists are now in Oxford

The number of students attending the various lectures is The number of students attending the various lectures in generic than on any previous occasion, more than 1 time having generic than on any previous occasion, more than 1 time having 500. A more rajed growth and a still greater measure of success attending the work may be attended from the fact that various County. Councils, finding themselves in possession of linds which they propose to derote to the purpose, of technical matrixion, are availing titemselves of the machinery of the Cunverty Extension system to accomplish this destructive description.

SCIENTIFIC SERIALS

In the Hotanical Gazette for June, Mr T. Holm contributes a study of some anatomical characters of North American grasses sumy on some anatomical characters of North American grasses In a paper entitled "On the Relation between Insects and the Forms and Characters of Flowers," Mr T Mechan epitomices his views on fertilization opposed to the current theory, via, that the part played by insects in the fertilization of flowers has that the pair pulyed by insects in the ferringation of flowers has been greatly exaggerated, that flowers do not abhor cross-polleu, and that all annuals can self-fertilize when cross-fertilization fails, annuals in almost all cases having every flower fertile

A. I. Batters. The Rev. H. G. Jameson concludes his key to the genera and species of British mosses, which it is hoped may be published in a separate form, and Mr. George Murray sinks Hooker's genus of sea-weeds Cladothele in Stretyonphon

SOCIETIES AND ACADEMIES.

Academy of Sciences, July 27 —M Duchartre in the chair — Proofs that Assa and America have beet connected in recent tunes, by M. Emile Blanchard. In this paper the author points out certain species of Asiate fanna and flora which are found in North America, as, in the preceding one, he indicated the representatives of European fauna and flora which occur in the same continent. Without making an extensive caumentation of the

different species, the facts brought forward give considerable support to the idea that Burope, Asia, and America have been sure to the idea that Burope, Asia, and America have been savaris from St. Columbo, by M. Albert Gandy. This is a decorption of an Jehhypaurus exhibited at the Paris Exhibition of 1859. It is proposed to name the fossil Jethypaurus buy-origin discovered in gold withings from the environ of Bere-sowsk, by MM. Daubres and Stanlain Memour. The specimens camined weighted respectively 11% grams and 72 grams, and metal is very magnetic, but mindirest no polanty. Its density metal is very magnetic, but manifests no polarity metal is very magnetic, but manifests no polarity. Its density is 7.59. When treated with an acid it is sensibly attacked, but does not show the Widmanstatten figures as is the case when acid is applied to a clean face of meteoritic iron fact and the absence of nickel leads the authors to conclude that sact and the absence or meker leads the authors to conscue that the iron is truly native. About one per cent of platinum is present—On the volatility of nickel under the influence of hydrochioric acid, by M. P. Schutzenberger. When dry hydrogen is passed over pure anhydrous nickel chloride at a red heat, it may be shown that the hydrochloric acid gas which comes off from the tube in which the reduction occurs contains a sensible amount of metal in the form of a volatile product.

The same result is obtained if, instead of reducing nickel chloride The same result is obtained if, instead of reducing mickel chloride by hydrogen, finely divided mickel is nacted on by dry hydro-you have a supposed of the control of the constitution. Note on a projected Observatory on Mont Hane, by M I Isansen—On the retardation of Jaminous impressions, by M Isansen—On the retardation of pressions of the Endouse geometrical representation and formula expressing the law of the passage of pericet gases through ordices, by M. Henri Partetty—On the dentaties of oxygen, hydrogen, and introgen, oxygen oxygen to 2005, introgen 4 4720. Now the dentaties of oxygen oxygen o 1050, nitrogen 4 9720. From the densities of oxygen oxygen o 1050, nitrogen 4 9720. From the densities of oxygen and nitrogen the percentage proportion of the former element in as is found to be 33 335 by weight and 21 026 by volume. The atomic weight of nitrogen deduced from these results vs 13 99, and that of oxygen 15 905.—Remarks on the transport of metallic tron and nickel by carbon monoxide, by N Julies Garmer. Some observations of the character of the flames issuing from furnaces. in which these metals are being reduced are shown to be easily in which these metals are noting reduced are shown to be easily explained in the light of recent work on iron and nickel carbonyls.—Action of water on the basic salts of copper, by MM. G. Rousteau and G. Tite. Certain borates and oxychloride of antimony are transformed to oxides by the prolonged. action of water at a sufficiently high temperature Similarly, by heating copper nitrate, brochantite, and atacamite with water in sealed tubes they have been reduced to oxides Libethenite has been experimented upon, but has resisted the transformation has been experimented upon, but has resisted the transformation even when kept in the presence of water for three days at a temperature of 275°C—On an actual mode of formation of mineral sulphide, by N E Chanda—Researches on thallum, by MM C Lepterre and M Lachaud Thallum obronastic base the presence of the control of the control of the base prepared by acting on thallum sulphate with potential that the control of the control of the control of the On patterns of the control of the heat of combustion of parabanic acid is found to be 212 7 cal, of oxaluric acid 211 cal. Hence the heats of formation have been calculated, 139'2 cal. and 209'9 cal. The heat of solution of parahamic acid at 20° and with a concentration of the mol per litre is - 5 t cal. The formation from oxalic acid of its ureide. parabanic acid, gives + 2.2 cal and of its uramic acid, oxaluric acid, + 2.5 cal. The formation of the ureides thus gives only a feeble heat-liberation. Each of these acids dissolved in a large excess of potash yields the neutral potassium oxalate Potassium oxalurate has been prepared by dissolving the acid in its equioxaltrate has been prepared by dissorting the account at valent of potash and evaporating. Fine prismatic needles are obtained, differing from the salts of Menschatkin and Strecker The heat of neutralization of oxaltric acid is 30 2 cal., as against The heat of neutralization or oxamine was 15 to 2 cm., as again, and 42 cal for oxahe acid,—The transformation of galle need and tannin into benzoe acid, by M. Ch. Er. Guignet.—On the polymeric acids of ricinologic acid, by M. Scheuer Kestner—On the fermentation of bread, by M. Léon Boutroux. During an examination of the conditions essemial for the fermentation an examination of the conditions essential for the fermentation of breaf, the subtroop has obtained in species of years and three dispersity and Educational Intelligence 335 species of bacters. The parts played by each of these organisms is scientific Senals and described, and the conclusions in shally drawn that the fer-discribetes and Academics 335 mentation of bread consists essentially of a normal alcoholic Books, Pamphiets, and Serials Received 335 organisms.

fermentation of sugar pre-existing in the flour, and that only the yeast producing alcoholic fermentations are necessary; the ordinarily co-existing alteration of gluten is a subsidiary and unessential action due to some of the bacteria present.—On a therenogene substance murine, by M. THURSDAY, AUGUST 13, 1891.

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY

THIS Congress, the work of which we refer to in another column, which is now in full swing, promises to be one of the most important meetings of the kind that has ever been held not only in point of numbers, but also on account of the far reaching results likely to accrue from it

A remarkable combination of circumstances has contributed to its success. In the first place, it is held in the country which has been the pioneer of sanitary work; and then it has the patronage of Her Majesty the Oueen, who, it is well known, takes a deep personal interest in its success; and has as its President, not merely in an honorary sense, His Royal Highness the Prince of Wales, who presided and gave an admirable address of welcome at the splendid opening meeting on Monday in St James's Hall

This is the seventh of a series of similar Congresses which have been held in various parts of Europe, and one is tempted to ask what they have accomplished An answer is at once forthcoming The all-important question of quarantine has been discussed at several of these Congresses. Not to go farther back than the Congress at The Hague, held in 1884, we find, from the excellent reports issued by the editors of the Lancet, that then the feeling in Europe was so strongly opposed to the English views as to the mutility of quarantine and the superiority of our method of medical inspection, that the English delegate was not even allowed to explain the English position in the matter, but the discussion was peremptorily close i, on the ground that the subject had been sufficiently discussed on the previous day At the Vienna Congress, in 1887, quarantine was again discussed under the subject of cholera; and the veteran Pettenkoffer told the members of various countries present that they had only to follow the example of England, in looking after their systems of water-supply and sewerage, and in isolating cases of infectious disease, and they would be no more afraid of cholera than the English were, even with their continual communication with India, the home of that disease, and would have no need of quarantine, with all its vexatious and ineffective restrictions, and all its unnecessary interference with commerce. Now, Continental opinion is almost entirely on our side, and it is doubtful whether there will be any serious discussion on the

But there are many other subjects with which the Congress will interest itself, and about which such an interchange of views as can only be obtained at an International Congress must be of the greatest benefit The whole subject of bacteriology has grown up within the last few years, and one of the most important and best attended Sections of the Congress is devoted to it, many of the highest authorities on this subject having been attracted here to take past in the discussion under the presidency of Sir Joseph Lister. The abnormal prevalence of diphtheria, not only in our own large towns,

but also in those of other parts of Europe and in America. in many cities of which, especially in the Western States of North America, it has become a veritable plague, is likely to occasion an important discussion in Section I., under the presidency of Sir Joseph Fayrer, The mention of his name leads us to observe that India is well to the front in this Congress, for not only have a number of delegates been sent by her Provinces and Native States, but they have also largely contributed to the funds of the Congress

Influenza, too, our new plague, about which we seem to know so little, might be discussed, as to its mode of spread and methods of prevention, with great advantage at a meeting where so much experience from all parts of the world is focussed

An especial feature in this Congress is, as might be expected in England, the prominence which is given to engineering and architecture in connection with hygiene. there being two separate Sections devoted to these branches of the subject

The division of demography, too, which has been so much talked about on account of its name, which was up to the present time unfamiliar to Linglish ears, and which has been defined by some way as "the art of drawing the public," has attracted, under the presidency of Mr Francis Galton, many of the most eminent statisticians of Europe. whose discussions cannot fail to promote the attainment of more uniformity in the methods of statistical inquiries

This is an age of Congresses, and if they are, as it is universally agree! that they are, of any use at all, it is self-evident that the most useful and the most important are the international ones

A LIFE OF DARWIN

Charles Darwin His Life and Work By Charles

Frederick Holder (New York and London G P Putnam's Sons, 1891) BETWEEN the voluminous "Life and Letters" of

his father, by Prof Francis Darwin, and the brief epitome of Darwin's work, by Mr G T Bettany, published in 1887 in the "Great Writers" series, there has hitherto been a gap which has only been partially filled by such books as Grant Allen's "Charles Darwin" in the series of "English Worthies" In the first of the works mentioned, our great naturalist is chiefly allowed to speak for himself, while in the second we have a digest of his scientific achievements. Although it has been generally considered that the life of Darwin from the time of the return of the Beagle was too uneventful to make an interesting biography, we have always been of opinion that there existed sufficient material for a popular " Life" of the very greatest interest provided that this material could be skilfully and judiciously worked The work under notice supplies this want, and

American and English readers are now provided with a biography which is both entertaining and accurate

Of course the material out of which Mr. Holder has woven his story is for the most part to be found in Darwin's own writings, or in the "Life and Letters," and readers who turn to the pages of this book with the hope of finding new matter may be disappointed. But the very circumstance that out of the familiar records of the voyage of the Beagle, and the later writings of Darwin. the author has been enabled to construct such a very readable volume, is the best tribute to his skill

The task which Mr. Holder took up was by no means an easy one: the difficulty which he had to confront did not arise from paucity of material, but from a superabundance of records, owing to the very complete account of his own travels and observations which Darwin has bequeathed to us. To extract the salient points from these records, and to dress them up in the writer's own language, was a labour requiring considerable literary ability Mr Holder has shown that he was well qualified for the undertaking, and it is refreshing-after the "Summary of the Darwinian Theory," and similar productions to which we have recently been treated in this country-to find that an American naturalist is able to write an account of Darwin and his work in language expressing his own ideas on the subject, instead of stringing together a lot of disconnected quotations from Darwin's writings. Not the least praiseworthy feature of the book is the comparatively small number of extracts from the writings of his hero, the author is wise enough to recognize the fact that most reading naturalists may be supposed to be familiar with the text of the "Naturalist's Voyage," the "Origin of Species," and other Darwinian classics

The present volume is one of the "Leaders in Science" series, published by the firm of Putnam's Sons The author says in the preface -

"When the publishers proposed to me the subject of the present volume, a life of Charles Daiwin for American and English readers, I was particularly gratified with the suggestion that the work should be adapted to young readers as well as old It has always seemed to me that the life of Charles Darwin was one eminently fitted to be held up as an example to the youth of all lands. He stood as the central figure in the field of natural science in this century, and while it is yet too early to present his life with any approximation of its results upon the thought of the future, it is apparent to everyone that his influence upon the intellectual growth of the country, and upon biological science in particular, has been marked and epoch-making

"In the preparation of the work I have not attempted an analytical dissertation upon Darwin's life-work, neither have I discussed his theories or their possible effect upon the scientific world, but have simply presented the story of his life, that of one of the greatest naturalists of the age, a life of singular purity, the life of a man who, in loftiness of purpose and the accomplishment of grand results, was the centre of observation in his time, revered and honoured, yet maligned and attacked as few

Having thus defined his object, the author proceeds to narrate his story, beginning with the boy Darwin, passing on to his Cambridge career, and then leading us through the scenes of his wanderings as naturalist to the Beagle. The major portion of the volume (twelve out of the twenty chapters) is thus pleasantly filled up, all the little personal incidents which give colour to the individuality of the man are skilfully brought in, and here and there the author interposes observations of his own which help to throw light on the questions discussed and the facts recorded by Darwin. Having in view the taste of his younger readers, a number of full-page illustrations have been introduced, some being reproduced from author mentions the views of Bonnet, the doctrines of

Spry's "Voyage of the Challenger," others from Gosse's "Romance of Natural History," others from Brehm's "Natural History," from Figurer's works, and from the Century Magazine. Many of the illustrations are new, the frontispiece, representing Darwin in his garden with the squirrels running up him, being well worthy of notice

The working period of Darwin's life from the return of the Bearle to his death is dealt with in three chapters, in the course of which the author relates the history of the "Origin of Species," and the impetus given to the publication of that work by the independent discovery of the principle of natural selection by "Alfred Russel Wallace, a young Welsh naturalist, who was then travelling in the Malay country" This incident is of course familiar to all, but as an old story retold by a transatlantic admirer of Darwin it reads even now with the charm of freshness. The later works are referred to in chronological order, and in a succeeding chapter we have a catalogue of the honours conferred upon Darwin during his life The seventeenth chapter contains an account of the Darwin family, beginning with William Darwin, of Marton, near Gainsborough, in 1500, and concluding with Erasmus, elder brother of Charles Darwin, the friend of Carlyle, who was described by the latter in his "Reminiscences," and whose amiable character was more fully portrayed by Miss Julia Wedgwood in the Spectator in 1881 The latter description from the pen of Miss Wedgwood is given by Mr Holder in extenso

The narrative, as such, ends with the death of Darwin in 1882, and the reader will turn with renewed interest to the eighteenth and nineteenth chapters, containing Mr. Holder's account of the Darwinian theory The principles of this theory are fairly well expounded, considering the small amount of space which has been devoted to them Natural selection is illustrated by a happily chosen and original example from the animal kingdom, viz. the adaptive coloration of the fauna of the Sargasso Sea Another illustration of the principle is drawn from the vegetable world, viz. the evolution of a hairy seed adapted for acrial transport. The questions of geological time and the paleontological evidences of organic evolution are also touched upon, and here we think the author might have used more judgment. The formation of the chalk, for example, is not quite satisfactorily given, and the statement that the chalk cliffs of Dover have been elevated "by some convulsion of nature" (p. 185) will jar upon the geological susceptibilities of his readers. In a work intended for popular reading it would also have been safer to avoid any esumate of the time required for the denudation of the Weald, the more especially as Darwin himself admitted the unsoundness of such estimates by omitting this section in the later editions of the "Origin." The ancestry of the horse, and Prof. Marsh's discovery of the Odontornithes, are well brought in in connection with the palæontological evidence. We may point out in passing that the diagram illustrating the evolution of the horse, which fronts p. 62, is referred to both on pp. 189 and 190 as "the accompanying diagram," which is obviously an oversight.

In tracing the history of pre-Darwinian evolution, the

Thales and Anaxagoras, the speculations of Leibnitz, De Maillet, Wright, Lambert, Herschel, and La Place of Buffon he says.—

"Buffon was the naturalist of the day in the time of Louis XV and Louis XVI,"—a period somewhat famous for the restrictions which were placed upon men, and the demunications with which new and advanced ideas were received. Thus advanced thinkers found that their theories in many instances, instead of leading them on to fame, but oneed the doors of the Bastile.

"It is not improbable that Buffon was in accord with the feeling of the time, as while his great discursive work -'Histoire Naturelle,' of 1749-88 -- fully outlines the theory of evolution, in which he was a believer, it is done in an ironical, partly satirical manner, so that he could, if attacked, retreat by claiming that it was a satire on the advanced scientific thought of the time, he was ready to believe that from a single unit in the beginning might have descended all the various forms of existing animal and plant life. It is curious to note that this pioneer evolutionist suddenly corrects himself and says no: it is certain from revelation that every species was directly created by a separate fiat ' Wc may suspect that this secession from a position so broadly taken was forced upon the evolutionist. Perhaps the clergy gave him close and suggestive attention, and he was offered the offended orthodoxy Be this as it may, Buffon was one of the early delineators of the modern theory of evolution, and despite his piculiar attitude, history accords him this recognition

The works of Wolff, of Goethe, Geoffroy St. Hilaure Oken, Pander, Yon Baer, Shidheden and Schwann, Von Mohl and Max Schultze, Lord Monboddo and Erasmus Darwin, are all referred to in often order, and a well-bestowed paragraph of praise is given to Lumarck Letter writers, such as Robert Chambers, Von Himboldt, Owen, Asa Caray, Herbert Spencer, and Youmans, bring us down to the both of modern Darwinism

To English readers the last (twentieth, but erroneously headed eighteenth) chapter will be one of the most interesting It is entitled "The Darwin Memorial," and contains a series of addresses by American men of science, delivered at a special memorial meeting of the Biological Society of Washington soon after the death of the illustrious naturalist in 1882. The address of Dr. Theodore Gill, of the Smithsonian Institution, is a masterpiece of eloquence, treating of "The Doctrine of Darwin," and contrasting the doctrines of special creation and evolution The address by William Dall, of the United States National Museum, is equally cloquent, and treats of Darwin in the form of a biographical sketch. Dr. John Powell, the Director of the United States Geological Survey, follows with an admirable address on "Darwin's Contributions to Philosophy." We cannot refrain from transcribing some of his remarks.

"But Darwin's investigations have not ended research or completed philosophy. He brought scientific men to the frontiers of truth, and showed them a path across the border. Yet more than this be did. He pointed out one time philosophers talked about deductive methods and inductive methods. Darwin has taught us that both are fruitless. . . By inductive methods, men are to collect facts, unbiased by opinions or preconceived theories. They are to gather the facts, put them together, arrange railingtions, But there are facts and facts—facts with

value, and facts without value. The indiscriminate gathering of facts leads to no important discoveries. Men might devote themselves to counting the leaves on the trees, the blades of grass in the meadows, the grains of sand on the sea-shore, they might weigh each one and measure each one, and go on collecting such facts until libraries were filled and the minds of men buried under their weight, and no addition would be made to philosophy thereby I here must be some method of selecting. some method of determining what facts are valuable and what facts are trivial The fool collects facts, the wise man selects them Amid the multiplicity of facts in the universe, how does the wise man choose for his use? The tiue scientific man walks not at random through the world, making notes of what he sees, he chooses some narrow field of investigation. always suggested by some hypothesis—some supposition of what he may discover lie may find that his hypothesis is wrong, and discover something else, but without an hypothesis he discovers nothing Working hypotheses are the instruments with which scientific men select facts By them, reason and imagination are conjoined, and all the powers of the mind employed in research "

The succeeding additess, by Dr C V Roley, gives an account of Darwin Sentonological work, and comprises a graphic description of the naturalist in his home, drawn from personal reminiscences of a visit to Down Dr Lester Ward follows with his address on "Darwin as a Botanist," in the course of which he discusses, among other points, the betring of Darwin's researches on the power of moment in plants on the great question wrapped up in the expression "tendency to vary" Dr Frank Baker contributes the next addless, on the expression of the emotions, and in this we again meet with a spirited advocacy of the Darwinnan method —

"But not as a fact-gatherer do we find him greatest Many others have struggled with an-like toll to annas piles of facts, which, like the ant-heap, remain but sand after ill. Darwin brings to his wook as informing spirit, the genus of scientific hypothesis. Hreithed upon by this spirit, the dry bones of fact coune together. "bune to his bone, 'the sinews and the flesh come upon them, they became alive about the state of the state

A Darwinian bibliography, by Frederick W. True, the Libratism of the United States, National Misseum, and an appendix giving a list of Darwin's works, conclude a volume of which enough has been said to commend it to all readers, whether youthful or adult, and which we on this side of the Atlantic cannot but appreciate as a most inspiriting pretire of the life and work of the man who, of all others, has helped to emblacion our country's fame on the screnific second of the numberenth century.

R MLLDOIA

PINES AND FIRE OF JAPAN

Monographie der Abietineen des Japanischen Reiches. Bearbeitet von Dr Heinrich Mayr Mit 7 Coloriten Tafeln. (Munchen M Nieger'sche Universitäts Buchbandlung, 1890)

FROM the time of Kaempfer and that of Thunberg to our own day, the Japanese Conifers have been the objects of special predilection on the part of botanists.

Juccanni figured and described several that had been collected by Sebold, Lndley, Andrew Murray, Maximowice, Franchet, and others, contributed greatly to the elucidation and delimitation of the several species Robert Fortune, John Gould Vertch, and Charles Marses Introduced many to our gardens. Horticulure has, indeed, rendered great service in this matter. The trees in question are valuable for ornamental purposes, and potentially as timber trees. The consequence of this is that collectors have accumulated specumens in large that collectors have accumulated specumens in large moreover, supplied our insergemen with seed, so that young plants are now numerous in our nurseries and plantations.

The study of the seedling plants, in their progress from the seed-bed towards maturity, has afforded valuable evidence concerning the morphology of the group and its probable genealogy, its filiation and classification Cultivation has, for instance, shown that many of the very curfous forms known under the name of Reinso spora are, in reality, stages of growth of one, or at least of a few, species of Thuya, of Cupressus, or of Junperus, so that the so-called genus is purely ficitious. In hik manner Abust hifids and Abus, forma have been proved to belong to one and the same species

To fill up the gaps in our knowledge, and to correct errors arising from inadequate or imperfect material, it was necessary that the trees should be studied by a trained observer in the forests themselves This was the more necessary as, to a large extent, our knowledge has been derived from plants cultivated by the Japanese and in some cases, not a little distorted in the process earlier botanists had little or no opportunities of studying the native flora for themselves Even Fortune was largely dependent on the Japanese nurserymen John Veitch collected for himself on Fusi-yama, and Maries penetrated even to the forests of Yesso Dr Mayr, the latest writer on these plants, has enjoyed opportunities denied to his predecessors. After a distinguished career in Munich, Dr. Mayr proceeded to the United States, visiting the forests in all parts of the Union, and producing, as a result, a work which the best judges speak of in terms of high appreciation. Subsequently, our author visited Japan to organize the Forest Department, and fill the office of Professor of Forestry in the Imperial University of Tokio In the execution of his duties Dr Mayr travelled through the various provinces, and derived much information from the native foresters. One result is before us in the shape of a volume, printed in German at Tokio, and illustrated with seven coloured plates. The group specially studied by Dr. Mayr is remarkable for the relatively large number of endemic species Thus, Dr Mayr enumerates six species of Abies, all of which are peculiar to the Japanese islands. Five species of Picea are nearly as much restricted in geographical area. Tsuga, a genus represented in both the Northeastern and the North-western States of America, as well as in the Himalayas, has two species peculiar to Japan The genus Larix, which also has a wide distribution in the northern hemisphere, has two species native to Japan, and not extending far beyond its limits. Six species of Pinus are enumerated by Dr Mayr, and these also are almost exclusively Japanese, though some are found on the mainland adjoining.

The Japanese islands, then, form a centre of distribution of a group of species of a distinct character, differing markedly from a similar group of Chinese nativity, but approximating to the Californian and to the East American conferous floras, and having representatives in other parts of Northern Asia and of Europe The distinct character of the Japanese Considers and their relationships are even more prominently brought into view when the other tribes of Confeis sare considered. Dr. Mayr confines himself, however, to the Abietineze, and we must here follow his example; in the hope that on another occasion we may be able to accompany him also through the other tribes.

In speaking of the distribution of these plants, Dr Mayr alludes (1) to the tropical zone in which the genus Podocarpus is represented, but which does not specially concern us now. (2) to a sub-tropical zone in which are other two species of Podocarpus, as well as Pinus Thunbergu, which extends round the coast of all the islands, and less frequently Pinus densiflora. (3) a region of deciduous trees, such as chestnuts in the south or at the base of the mountains, or beeches and birches to the northward or at higher altitudes. Here grow especially the Cryptomeria, the various species of Chamacoparis, Thuyopsis, and Sciadopitys (4) The fourth zone, that of firs and spruces, occupies the high mountains in the centre of the Island Here are found Abies Vestchis, Puca bicolor, P Hondoenius, and Larix leptolepis, which are peculiar to the main island, together with A Mariesi, A sachalmensis, Picea araneusis, and P. Glehm, which extend northward, some even as far as the Sachalin and Kurile Islands Tsuga diversifolia occurs from the region of the beech upwards to the Alpine cone (5) The fifth, or Alpine region, also designated that of the Alpine pines, includes forms such as Pinus pumila, which is allied to the Swiss P Cembra We can only indicate these regions, as the discussion of their climatal features and plant population turns mainly upon plants different from those which form the staple of Dr Mayr's present treatise

Passing into detail, Dr. Mayr proceeds to describe each species separately, devoting much space to hierary references, Japanese as well as European, and giving a description of the main peculiarities of the tree from an economic as well as from a botanical aspect.

A few new species are indicated, of the value of which we can hardly form a trustworthy opinion in the absence of authentic specimens. We venture, however, to doubt whether Abies homolefus is, as, however, others beades. Dr Mayr think, identical with A. trachythyl/la. The leaf structure of the two is certainly different, and cultivation may yet reveal other differences. The names bicolor, Allockiania, apaments, pistonicis, pidomicis, microsperma, as applied to one rimore species of Picca, have been so vanously understood by botanists, owing partly to acceleratal insplacement of labels, admixture of seeds, and to imperfect information, that it is very important to have an authoritative statement from such an observer as Dr. Mayr If allowances be made for a large amount of variability within the conventional specific limitations, it

would seem from the figure as if Dr Mayr's Pinus pumila might be referred to P Cembra, whilst P. pentaphylla is obviously a near ally of the East American P strobus

Dr. Mayr's "diagnose," however, is really a rather description in German, not conveniently adapted for the comparison of one form with another. In this absence of concise comparisons in Latin, modern bodiantist, especially German ones, compare unfavourably with their prefecessors. On the other hand, Dr Mayr establishes some sectional characters which may prove useful, such as the three sections into which he divides the genus Pirea, w. Monthad, Caseita, and Omorica, the last, indeed, having been already proposed by Wilkomm

Hybrid forms between Praus Thusbergs and P denufors are mentioned, as well as a whole series of garden varieties which have either originated in Japanese gardens or have occurred as "sports" on the wild trees, and which have been propagated by grafting by the Japanese gardeners. These are likely to prove of scientific interest, and will be shecally interesting for garden purposes

Seven quarto coloured lithographic plates accompany the volume, giving details of the foliage and cones. We could have wished that representations of the trees themselves could have been upplied, and that an alphabetical index of species and varieties had been added to the classified table of contents. When we have so much that is valuable and interesting presented to us, it may seem ungracious to hint at deficiencies, but really in this acea to ask for more shows how greatly we appreciate what we have, and is about the greatest compliment we can pay to the author.

ELEMENTARY HYDROSTATICS

Solutions of Evamples in Elementary Hydrostatics By W. H. Besant, Sc. D., F.R. S., Fellow of St. John's College, Cambridge (Cambridge, Deighton, Bell, and Co., 1891)

THIS is a collection of solutions, or a crib, to the author's well-known "Elementary Hydrostatics," which has held the ground in elementary instruction unchallenged since 1803

It was cruel, though, as Dr Besant apologetically explains, unavoidable, to keep the world of instructors waiting so long for these much-needed solutions and explanations of the questions in his Hydrostatics

The Solutions are stated to be almost entirely drawn up by Mr A W Flux, who has found it necessary to explain that the equation $\hat{p} = p_0 \pi$ must be interpreted as giving the pressure \hat{p} in pointials per square food for in C.G.S. boson's, mught well have been added); but he has not explained that the effect of this reverential interpretation is to make p and w signify the same thing, so that two symbols are used to denote the same quantity, although one, p, is called the denity, and the other, w, the further weight.

But in 1863 the word poundal was not known, nor was any mode of measuring force and pressure in use, except in terms of gravitation units,

It would take too long to recount the despair of the instructor and the confusion of the stulent at the different

modes of reconciliation of the equations p = xpx and p = xpx, variously used as measuring the pressure at a death of x feet

Because thirty and more years ago it was thought convenient in dynamical equations to replace W/c by a single letter M, merely for purposes of convenience in writing and printing, it was and is still taught in our theoretical treatises that the equation $W = M_c$ is the expression of a subtle and fundamental law of Nature, to be introduced even into a treatise on Elementary Hydrostatics, presumably taken up before a student has commenced Dynamics, and before he can understand what acceleration in general, and the particular acceleration R, can mean.

What mist, for instance, be the feeling of Tommy Aikins, when the Musketry Instructor begins on p i of the official "Treatise on Military Small Arms," 1888, with this definition of Mass, taken in a garbled form from chapter in of the Hydrostances and el-ewhere

"Mass The quantity of matter in any body, the sum of all the particles of the body; it is proportional to the weight, whatever be the figure, or whether the bulk or magnitude be great or small; for the weight is equal to the mass multiplied by the force of gravity, or W = MC, and the letters M and W are usually employed to denote the mass and awayfat respectively"

In short, this definition amounts to saying that mast is something we denote by the letter M, while warght is something we denote by the letter W, but we must always remember that W = Mc, where g is something unexplanted, even when we measure mass in pounds and weight also in pounds, so that if g appears in one place, it will cancel again somewhere else, and not affect the ultimate numerical result

But if, according to former instructions, we calculate the pressure from the equation $\beta=e_{PR}$, we must notice that β , the density as defined in chapter in , "Elementary Hydrostatics," is the weight in pounds of one-gift any of a cubic foot of the liquid, or β is the weight in pounds of one cubic foot of the liquid, so that g_P and w now measure the same quantity

The unfortunate instructor was formerly called upon to reconcile these opposing statements, that w is sometimes the same as ρ , and sometimes as $e\rho$, now, however, he can take refuge behind the definite statements of this authorized collection of solutions.

But what is most wanted is a mathematical Censorship, to go through our hydrostatical treatises, expunging all the r's.

As to the mere mathematical geometrical part of the solutions, this is doublets carried out with rine Cambridge elegance, of which Dr. Beant is so well known an exponent, a time however, in comparison with the difficulty of the interpretation of the units in some extraordinary questions relating to the equations W = gpV, questions at one time considered a valuable test of clear thinking on the part of the student.

We counsel everyone who values his peace of mind to procure a copy of these Solutions, if called upon to interpret and expound the numerical results of the original "Elementary Hydrostatics"

A G GREENHILL

OUR BOOK SHELF.

Plane Trigonometry for the Use of Colleges and Schools
With numerous Examples By I. Todhunter, F.R.S.
Revised by R. W. Hogg (London Macmillan and Co., 1801)

TODHUNIER's "Trigonometry" is a very familiar friend of ours, and we have now before us a bundle of letters which we received from the author in 1861 and 1862, in reply to our criticisms and corrections of the early editions The first edition swarmed with small errata, for the pointing out of which we received warm thanks was a good book for some years, on account of the excellent collection of problems, but of late it sadly wanted bringing up to date Mr. Hogg has done his work well, but possibly he would have produced a better independent book The first 200 pages have undergone very little change, and we have only noted here and there an interpolated article Chapter avin, "Miscellaneous Propositions," contains several novelties (as contrasted with the last edition we have of the original work), such as geometrical proofs of familiar formula and graphs of the trigonometrical functions There are numerous important additions in chapters xxi -xxiv, which bring this part of the work more en rapport with present day requirements, notably Schlomilch's resolution of $\sin \theta$ into factors, and a too brief account of hyperbolic functions. The prime feature is the addition of a very great number of excellent recent exercises in all parts of the subject. The work forms a good school-book, and will meet the requirements of a large number of students.

Lessons in Astronomy By C A. Young, Ph.D. LL.D. (Bosson, U.S.A., and London Ginn and Co.1, 807). THIS is the third of a series of text-books recently prepared by Prof. Young for use in schools and colleges of different grades. The two previous ones have already been noticed in Nat LORE (vol vxxx) p. 595, and vol in p. 483). The present work is described on the tutle page as "a schools and serimantes". The three books have much in common, and each one has many good points. We cannot help feeling, however, that the steps between them are too small. Almost exactly the same ground is covered by acid, and they differ chiefly in the amount of mathematics required for a thorough comprehension of the "General Astronomy" so po means great, and even for the "Lessons" a certain knowledge of geometrical principles is essential I we must needs have three books, the "General Astronomy" contains too little, and much. Some "a book of some 550 pages—contains too much.

The chef variation calling for notice is in the portion chaining with uranography. This now forms chapter in, and, with the aid of the maps, forms a fairly complete and easy guide to the constellations. The notes on the legendary mythology of the constellations, which have been added for the benefit of students not acquainted with classical literature, gives this chapter an additional

The book is brought well up to date, and is a model of good printing

Cosmical Evolution · a New Theory of the Mechanism of Nature By Evan McLennan. (Chicago Donohue, Henneberry, and Co., 1800)

THE author states that the essential principle of the new theory is "that every known heavenly body is connected with its neighbouring heavenly bodies by means of real, material bonds, and that every phenomenon of the universe, without exception, is due solely to the action of bodies upon one another through, and by means of, these bonds which join them together" (p. 48)

NO. 1137, VOL. 44]

Among the principal evidences in favour of the existence of this material planetary connection is that "we actually see them with the naked eye" in the zodiacal light and in the streamers of the solar corona

The theory is of a very general nature, and includes not only cosmical but terrestrial phenomena, such as aerial and aqueous tides, terrestrial electricity and magnetism. The author is of opinion that "the greater tidal wave is due to the sun, and the lesser to the moon" (p. 291)

The conditions of prelunar and other races of mankind are also discussed (p 360) The work consists of 399 pages There is no index

The Telescope an Introduction to the Study of the Heavens By J W Williams. (London Swan Sonnenschein and Co., 1891)

THE writer of this book is author of "British Fossils, and where to Seek Them," and "Land and Water Shells, &c." In his preface he quotes with approval the adage, "Ground your knowledge of any special group on a general knowledge of mature as a whole." This is pullups why he now turns his attention from shells carefully compiled, and is to be recommended as a safe guide. Some of the illustrations are excellent.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Nither can he undertake to return, or to correspond with the worters of, rejected manuscripts intended for this or any other part of NATURE. No notices is taken of anonymous communications!

Silver Lodes and Salt Lakes

Shake the discovery, some five or us, years ago, of the extraontinuary links, in full lode of suber hearing ores, the public asentended with consumartuely little securities interest in regard to the geological features of the argentiferous country added to probable, origin of depoints so well and or reinstrabled in the probable, origin of depoints as over and or reinstrabled in the graphical and geological Features of the eastern pairs of South Astusials and the western parts of New South Wales will probably throw more light upon the interesting subject of the onigin of argentifeross lodes; than the study of usy other now known part of the globe, and, as I have had an opportunity of going do depended to the matter during a recent visit to Broken ground the state of the state of the control of the subject of the proportion of the subject of the which seem to afford presumptive evidence in favour of the supportion that sail takes and silve todes are exastly connected.

postton that sait lakes and slives lodes are causally connected.

An examination of the ores in this at Bloten Hill, and especially in the portions of the lode which are known as blocks to and it, reveals the fact that stantification almost exactly versal throughout the lode. So obvious has this been from the very beginning of the working, that almost every mining man who has had anything to do with Broken Hill has remarked upon the very obvious fact that the ores are to be ascribed to an aspectos when the said of th

ore took place, it is evident that the conditions at the time ore took place, it is evident that the conditions at the time must have been very different from what they are at present. The key to the whole situation teems to lie in the fact, which has been so well pointed out by Mr. Alfred Russel Wallace and others, that the whole of the regions of Central Australia and others, that the whole of the regions of Central Australia have emerged from the ocean at a period which, from a geo logical point of view, is comparatively recent. The axial lines of the watershed ranges appear to be rising at a more rapid rate than the neighbouring plains, and consequently some strange. and interesting changes are taking place in the relations of the eatchment areas of flood waters and their outlets. In the locality of Innamincka, almost due north from Broken Hill, there occurs a phenomenon which is obviously due to some such change of relations. The Strezlecki Creek runs to the south west from Innamincka. Its bed holds immense deposits of drift sand, and in the adjoining plains are to be seen many curious parallel ridges of sand-hills, all strongly suggestive of the action of drift ridges of sand-fulls, all strongly suggestive of the action of our water, such as at times passes across the surface of these vast interior plains at flood time. The Stretlecki Creek was apparently the outlet for most if not all of the water of Cooper's Creek at some period of time not at all remote. But at the Creek at some period in time not at all remove but at the present day it is only once in every four or five years, that the stream runs at all. When a very high flood fills the bed of the Cooper to overflowing, the waters find their way over the low ridge of land which separates the present bed of the Cooper from that of the Stretzlecki, and so on to Lake, Blanche and Gregory-those large salt evaporation pans which can scarcely Gregory—those large sait evaporation pains when con season, with propriety be dignified with the name of lakes. The gradual elevation of the low ridge would appear to be the most probable avalanation of this interesting phenomenon. Now, to the south of Broken Hill, and in the vicinity of the River Darling, there is to be found ample cyclence of a somewhat similar occurrence Vast accumulations of sand in parallel radges are still to be seen vast accumulations of sand in parallel ridges are still to be seen crossing the plains, and a large river bed extends, from a pluce quite close to the junction of the Darling and Murray, nonthwards in the direction of Broken 11bl. Whether this "Anabinach," as it is called, is really an old bed of the River Darling or not, I will not stay to imquire. It would, however, appear practically certain that some slight alteration in the level of the land has been responsible for the change in the direction of the flow of

The case is not an ordinary one of the diversion of a river owing to the accumulation of its own allwiums, and this and ordiges, which is place extend right down to the bad of the sand redges, which is place extend right down to the bad of the ward of the country of the control of the country of the control of the country of the present of the product of the country of the present of the product of the present country of the present of the product of the present of t

But this has not been the case in times gone by. The evidences of the action of water in the neighbourhood of the "Anabranch" makes it to appear practically celtain that at one time the flood waters, which is well through the sail takes, must found an outlet by that meant. This, then, briggs me to the most significant fact to which I wish to direct attention. The locality of Broken Hill is the lowest point in the axis of the line of country which forms what I have alluded to as the wild et al. In the absence of any survey from which fall data could be alluded, it is infriend to have the levels of all the ratlway deduced, it is infriend to have the levels of all the ratlway two miles north east of Broken Hill. These show that the ratlway which happens to follow the line of the ratley days gradually to Broken Hill, and then rises again towards Tarrisangle. The conclusions a therefore neutrals from the data

to which I have already referred, that Broken Hill is the locality at which the accumulations of flood water from the great region of the sait indees must have found their way across the connection of the sait indees must have found their way across the connection of the sait indees must have found their way across the connection of the sait indees must have found to the connection of the sait indees and the sait of the sait indees and the sa

A Magnificent Meteor

AF 115 a m, on July 31, I observed a most magnificest meteor—a versible Andomodes! It was much larger than Jupiter, which was on my right, in the constellation Pares, returned to yellow the properties of the properties of the properties of the properties of the yellow being opportunely blench, but it oboded at least to be called a fire-hall. It alluminated the whole district with the building of the properties of the prope

bright, but of short duration.

On the night of July 31, and on the morning of August 1, there was a brillium display of stars for this time of the year, the Milly Way was well defined from horzon to houson, denoting a cerum degree of front. At present, Jupite to the production of the present of the present, Jupite of the present of t

Bees and Honey-dew.

Nash here is an avenue of alternate beech and oak tuees, and, in walking through it, my attention has lately been drawn to a loud humming in the beeches, smilar to that heard in lime trees when in flower, while the oaks are widen. The sound is, if find, produced from here in search of the Aphis secretains on the leaves of the beeches, the under valed of which her witch. With the substance. The been appeared in the contract of the contract of the contract of the contract of the leaves affect, but past on the manging, and the under valed of the leaves affect, but past on the manging,

and then creep underneath, when, after running about and exhausting the supply, they fly off to another leaf, exactly as if they were visiting flowers. The leaves of the oaks are elean, and have no "honey-dew" on them F. M Burron. Highfield, Gainsborough, August 5

Dredging Products

Amongst the products of the dredgings which my friend the Rev. J. H. Crawford and I are procuring from the Voe here, I am glad to be able to record the presence of Actinotrocha. We only got two or three specimens at first, but to day a large only got two or three specimens at first, but to day a large number was procured from the surface net. One or two have attained to the Phoronis condition since being brought in. They answer in all respects to Actinotrocha branchiata, but seem to be as a rule less pigmented than the specimen found in St.

Activotrocha branchiata has no w been found on both sides of Activate cela is nucleated has now been found on both sides of Socialand and England, and also at Helippiand, but, bested being got in the North Sea and on the west coast of Britan (etd. NATURE, vol XXXV). It seems also to be found on the western aide of the Atlantic, for Wilson records it from Cheapacke Bay It is thus distinctly a northern form, but has a wider distribution than has hitherto been supposed.

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY

N EVER before, perhaps, in the history of science has there been assembled together such a numerous gathering of eminent inen of science of different nationalities, or representing so many countries, for the purpose of discussing scientific problems

Although it is little to the national credit that the imporance of international Conferences on Health was suggested by the Belgians and not by ourselves, the conditions we are under here must not be forgotten. All other civilized countries have strongly represented among their Ministers, and among administrators, men of knowledge and competence, and elsewhere such Congresses are treated as of national concern

Here, even in the matter of health, such powerful and economical methods of obtaining and distributing know-ledge, such as Congresses like the present afford, are absolutely ignored by the party politicians to whom we

commit our national welfare

There can be little doubt that most of the good which is certain to alise from the deliberations now going on must be ascribed to the Queen and Prince of Wales, who must be ascribed to the Queen and Prince of Wales, who came forward as Patron and President of a Congress ignored, as we have said, by our party rulers This has been pointed out by the St James's Gazette—"The Prince of Wales has rendered a not inconsiderable service to his country by good naturedly pulling the Con-gress out of the fire, and rendering a partial success of gress out or the fire, and rendering a partial success of what came near to being a sad faux. But for his complaisance in sacrificing his holiday in coming up to London to take the chair, no public personage would have been present to welcome the two or three thousand. guests bidden to the metropolis, or to give attraction and dignity to the opening meeting There are three Ministers whose departments have relation to the sub-jects treated by the Congress. Mr. Ritchie, who is our quan Minister of public health and relief, Mr. Chaplin, whose department deals with the hygiene and prevention of disease of animals; and Lord Cranbrook, who controls medical education Not one of these Ministers was present yesterday. Not even the Registrar-General, the tive of the Home Secretary, took part in yesterday's "meening The Prince, however, saved the position '

The devoted and enpaid labours of many eminent men have, however, with this slight touch of rational feeling

in high quarters, already rendered the success of the Congress unparalleled, and it is really wonderful to see Congress unparalleled, and it is reany wonderful to see what they have done, in spite of the enormous difficulty of arranging for a large number of people in such a city as London. Even the facilities afforded by Burlington House and the University of London buildings do not include a hall large enough for an adequate reception room; at first, therefore, there were difficulties, largely owing to its absence. This will hardly be wondered at, when we state that the numbers enrolled already are about 3000, and that there are 40 delegates from the German Empire and 70 from India, only to give two instances.

In anticipation of the meeting, among other official documents too numerous to mention, was prepared a Hand-book to London, with special reference to the needs of the members This is a volume of 250 pages, in French and English, with eight plates showing the position of hospitals, cemeteries, markets, and the like I his has been published by Messrs Cassell There is another volume of 233 pages, containing abstracts of the more important papers pages, containing abstacts of the more important papers to be read. Nor have the English Committee been the only workers. We have "Denmark its Medical Organization, Hygiene, and Demography," with numerous illustrations and maps, published in English by authority. of the Danish Government in time for the International Congress This has been published by Messrs Chuichill

In spite of the abstentation of any notice on behalf of the Government, it is pleasant to note the way in which the Lord Mayor and the Corporation, the Royal Colleges of Physicians and Surgeons, and numerous other public bodies and private individuals have kept up the credit of the nation for hospitality Among the conver-sations must be specially mentioned that at the Guildhall on Tucsday evening, when the Loid Mayor received the members of the Congress It was a brilliant and impressive sight, enhanced by the uniforms of foreign officers, and the unfamiliar garbs of members of our own distant dependencies The various social arrangements made by the organizing committee are recorded in a special pamphlet of fourteen pages

The proceedings began on Monday by a meeting in St. ames's Hall, presided over by the Prince of Wales Douglas Galton first presented the Report of the Permanent International Committee, and inter alsa gave the

following account of the general organization -

"The work of the Congress has been arranged in two divisions, viz hygiene and demography, and it has been found necessary to divide the former into nine sections, each under a separate president, and with separate organization Committees have been organized in foreign countries to further the interests of the Congress in a more direct manner than could be done from England Delegates have been appointed by all the Governments of Europe, and also by the United States, Mexico, Venezuela, Japan, Persia, Egypt, by the provinces and native states of the Empire of India, by the most important colonies, and also by numerous municipal authorities, universities, scientific and medical societies, and other institutions throughout the world, and large numbers of the most important authorities on the subjects to be treated of have sent communications to be laid before the Congress."

After the reading of this Report, the Prince of Wales

opened the proceedings by a careful and sympathetic address. One part of it referred to the dangers to health inevitable to the conditions under which we live. He remarked in relation to these dangers.—

"It will be no trivial work if their sources and probable remedies can be clearly pointed out, and especially if this can be done, as in a Congress such as this it should be, in a strictly scientific manner, calmly and dispassionately, without any reference to either general or municipal politics, or for any other purpose than the promotion of health It is only on conviction such as may thus be produced that the appointed sanitary authorities can compel the changes necessary to be made; for such changes are almost always inconvenient or injurious to some, and might even seem unjust to them, unless it be made quite clear that they would be very beneficial to the community But my hope is that the work of this Congress may not be limited to the influence which it may exercise on sanitary authorities It will have a still better influence if it will teach all people in all classes of society how much everyone may do for the improvement of the sanitary conditions among which he has to live I say distinctly all classes, for although the heaviest penalties of insanitary arrangements fall on the poor, who are themselves least able to prevent or bear them, yet no class is free from their dangers or sufficiently careful to avert them Where could one find a family which has not in some of its members suffered from typhoid fever or diphtheria, or others of those illnesses which are especially called 'preventable diseases'? Where is there a family in which it might not be asked, 'If preventable, why not prevented?' I would add that the questions before the Congress, and in which all should take a personal interest. do not relate only to the prevention of death or of serious diseases, but to the maintenance of the conditions in which the greatest working power may be sustained

The Times, in a leading article on the Prince's address, points out one very important practical matter in which we lag far behind many foreign countries, and which may serve as an excellent illustration of the Prince's words about inconvenience or apparent injustice to individuals "The weak point of English sanitary law is in respect of regulations for the slaughter of animals" In London, for example, slaughterhouses are small private establishments, often situate up little alleys or courts, surrounded by dwelling-houses, and not only destitute of many conveniences which they should possess, but also affording great facilities for the slaughter of diseased animals, and for the distribution of their flesh as food. In many Continental cities public abattors have been established upon a large scale, and all private slaughtering is forbidden At these abattorrs there is an abundance of space, of air, of light, there is an excellent water supply, and the slaughtering is conducted under the supervision of officials, governed by rules which not only protect cattle against unnecessary cruelty or ill-usage but which provide for the systematic inspection of meat before it is permitted to be sold. We shall certainly hear a good deal, during the sitting of the Congress, as to the importance of preventing the consumption of the flesh of tuberculous animals; but this, however important it may be, can never be done while the innumerable small private slaughterhouses are suffered to remain.'

At the conclusion of the Prince's address, speeches were delivered by representatives of France, Italy, Austria-Hungary, Saxony, and Prussia It is pleasing to record that all bore high tribute to the part which has been played by England in the promotion of measures calculated to preserve and improve the public health. On this point, Dr. Brouardel (France) was indeed specially emphatic -

"In the year 1837, the year of the coronation of Her Gracious Majesty, appeared the Act which rendered obligatory the registration of deaths Act maugurated the era of administrative reforms concerning the public health which our valued colleague of the Local Government Board has rightly called 'the Victorian era' This Act did not long remain alone. Under the impulse given by two of your most illustrious patriots, William Farr and Edwin Chadwick, you have organized a system of registration of the causes of diseases and of deaths Certain important cities, before the law made it obligatory, obtained supplies of water beyond all suspicion of pollution, and adopted systems

cities, whose action cannot be too much praised, the sickness and death rates diminished rapidly, this furnished the necessary proof it was time for reform Twenty vears ago the Local Government Board was established. years ago the Local Government noard was emousined, and in 1875 had submitted to Parliament a Bill for the protection of the public health During its discussion in Parliament none of your greatest Ministers (Disraeli) pronounced in the House of Commons these memorable words, which should be repeated in all countries and in all Parliaments 'The public health is the foundation on which repose the happiness of the people and the power of a country The care of the public health is the first duty of a statesman' Since this, each year you have made fresh improvements in your sanitary laws, if in your eyes they are not perfect, in the eyes of the nations who surround you they are an ideal towards which all their most ardent aspirations tend It is you example they invoke when they claim from the public authorities the powers necessary to oppose epidemics, to combat the scourges which decumate their populations. You have taken the first health: this is not all that you have done in the domain of hygiene Among the diseases which one can properly term pestilential, there are, thanks to the work of the hygienists of all countries, certain ones which from the present time may be considered as preventable such are small pox, typhoid fever, dysentery, and cholera For one of these, the most terrible, the immunity conferred by vaccination is absolute. The person upon whom this immunity is conferred can pass through the most severe cpidemics, and expose himself to all sources of contagion without being affected. Who is it who thus preserves from death, from blindness, from infirmity, millions of human beings of all countries and of all races? On May 18, 1796, a date which might well be the date of a great battle, Jenner moculated with vaccine matter by means of two superficial incisions, the youth James Phipps Protection against small pox belongs to you, the world will be to you for ever obliged let us consider two other epidemic diseases. Is it possible to establish the conditions of propagation of typhoid fever without quoting the names of Budd or of Murchison ! I am aware that in 1855 Dr. Michel de Chaumont had for the town in which he lived experimentally established the rôle played by drinking-water in the propagation of this disease. Unhappily, public opinion was not prepared, and his discovery was not listened to In the work which we are considering, the efforts of the English school were most fruitful May I recall the fact that it was the epidemic of cholera in 1866 in England, which gave birth to the theory of its propagation by drinking-water? Was it not at that date that, under the influence of your hygienists, the Lords of the Privy Council issued an order formulating the laws of prevention which we adopt to-day? Certain it is that even in England these discoveries liave not immediately borne all their fruit. The anti-vaccination leagues are not yet dead Proofs accumulated during a century have not sufficed to cure that mental blindness which is congenial . Can France be represented in a Congress of Hygiene without recalling the name of M Pasteur? For centuries we have asserted that epidenne diseases were propagated by means of contact, by the air, by the effluvia, by miasmata The idea of morbific germs, if not the name, is even found in the works of Hippocrates, but in what an uncertain sense The theory of contagion has passed from century to century with strange modifications; the uncertainty of the methods of research and the difficulties of observation bound up together truth and error It remained for Pasteur to prove the existence of these germs, their form, their life, their mode of action, and by their attenuation to solve the problem of immunity Thanks to his work, and beyond all suspicion of pollution, and adopted systems thanks to those of his pupils, icalities have succeeded to of removal of foul water and waste matters. In these contingent possibilities. We know some of our enemies. their habits, and their mode of penetrating the body; u po this time main was conquered by these infinitesimal beings, but, thanks to recent discoveries, he will be their conqueror When, at the beginning of a century, one can inscribe the race may reque: More hab been done for it against misery, deases, and death than in any one of the centuries which have preceded it. You, gentlemen, you have been the mitators, this rule will never be dispated with you by the preceding the property of the

Dr. Van Coler, the Medical Director-General of the Prussian Army, the representative of the German Government, followed suit, and showed the aid tendered to armies by the improvements in sanitary science. We give the following short extracts from his speech.— "It is indeed with a feeling of joyous pride that from this

place and in this country, where we have to trace the very cradle of all modern science of public health, I am permitted to point out how the many efforts made in the direction of hygiene radiating from I ngland were, especially in Germany, hailed with much delight, where they received the most careful attention, and where they ever since have been most actively promoted . If from our army, diseases like malaria, small-pox, dysentery, have completely, or almost completely, disappeared. If typhus fever and diphtheria become more and more diseases of the past, we have to be thankful for these attainments to the development and application of hygiene It is now an established fact that infectious diseases are by no means a necessary evil in the army I hey are simply diseases which can be avoided, which can be powerfully opposed, and against which the science of our days battles vic-toriously with ever-increasing success."

Dr Korosi's address will be welcome to many, as he exactly defined demography—which is a puzzle to many outsiders—and pointed out the early work done by mem-

bers of the Royal Sucrety -

This branch of science, the very nucleus of statistical work, which, in fact, is quite a science in its own right, has chosen the task to investigate the laws which regulate the life, increase, and decrease of nations. Its work, therefore, comprises three main parts statistics of natality, of mortality (his patt including biometry, the science of measuring the duration of human life), and of the increase of population. And when inquiring now who were the founders of this new science, we shall hear unanimously quoted the names of England's sons-Graunt, Petty, Halley, Malthus Gentlemen, to-morrow, when we are to begin our work, we shall meet within the venerable hall of the Royal Society The representatives of demography must feel a deep emotion when entering those rooms, which are so intimately connected with the history of their science, for this is the place where, 220 years ago, demography was created. It was in those halls, in their very first youth then, but soon conspicuous to the whole world by the genus of Newton, that appeared the work of Graunt which forms the startingpoint of demography, and here the King himself, admirably appreciating the work done, recommended the author to be received as a member of the learned Society It was there that shortly afterwards Sir William Petty, by his eminent power, raised the new science to political importance and to popularity, and in the same place, again, in 1693, the famous Halley became the founder of the most important part of demography, of

halls shy and even without a name, has found its way over the whole globe. Having been worked out in Germany, having received a name and new ideas in France, and having been enlarged and imbued with a more scientific character by Quetelet, having got its well-equip ed office in every country of the civilized world, we are groud to see now its numerous representatives meet at the same place where two centuries ago this science was born. After a triumphant career of 220 years, it returns to its home, to the old rooms in which it awoke to light, and again the Throne of England receives it with favour and benevolent interest For demography not less than for all statistical work, it is of the highest importance that its representa-tives, scattered as they are over the whole globe, should fully understand each other, for only so we can accomplish our aim, that our observations comprise equally all countries of the world, that our researches are conducted and worked out on the same principles everywhere, and that we may unite the incomplete and often discrepant descriptions of the single nations to a full descriptive history of the whole of civilized mankind This great aim fully deserves the praise the illustrious Prince Consort bestowed upon it from this very place thirty years ago He said, 'The importance of the Congresses cannot be over-rated, they not only awaken public attention to the value of these pursuits, bring together men of all countries who devote their lives to them, and who are thus enabled to exchange their thoughts and varied experiences, but they pave the way to an agreement among different Covernments and nations to follow up these common inquiries in a common spirit by a common method and for a common end?"

The meeting was subsequently addressed by Sir James Paget, Dr. G. Buchanan (of the Local Government Board), and others

The Sectional work of the Congress began on Tuesday. The Divisions and Sections are as follow. —

any most Disbastion of President, and the president, but Joseph Fayrer, K C SI — Section 2 Batteriology President, shr Joseph Baster, Bart — Section 3 Batteriology President, shr Joseph Baster, Bart — Section 4 Infancy, Childhood, and School Life—Section 5 Infancy, Childhood, and School Life—President, shr Henry Roscoe, M P — Section 6 Architecture in Relation to Hygene President, 5r Arthur W Biomfield, A R A — Section 7 Linguisering in Relation Section 8 Children President, John State Batterion Company and District President, Section 8 Children Section 8 Ch

Division 11 - Demography President, Mr Francis

We shall endeavour next week to give an idea of the sessits of the many important discussions which may be anticipated, but it is already clear that it will be impossible for us to give anything like a full report, for the programme of work to be gone through is enormous The addresses of the various presidents on the opening day were in themselves important communications, and well fitted to give tone to the subsequent discussions.

PROGRAMME OF TECHNOLOGICAL EXAMINATIONS.

A SIGN of the general advance in technical education author to be received as a member of the learned Society. It was there that shortly afterwards Six Wilham Petty, by his eminent power, raised the new science to political importance and to popularity, and in the same place, again, in 1693, the famous Halley became the clouder of the most important part of demography, of biometry, by working out the first table of mortality. And the conditions of the more important trades as practised one whe young science, which two centures ago left those

of the sixty subjects are divided into different sections. corresponding to the separate branches of the same trade, or to the practice of the trade in separate localities.

In the new Programme we notice many important additions A practical test, which is the surest preventive of cram, and excludes those who are not engaged in the trade from presenting themselves for examination, has been added to the syllabus of nearly all the subjects. Thus, next year, for the first time, there will be practical examinations in such widely different subjects as photography and boot and shoe manufacture In many subjects dealing largely with the practical applications of science the syllabus has been entirely re-written. This is the case with "Electrical Lingmeering," which is now divided into two main subjects—"Telegraphy" and "The Transmission of Power"—the former being again subdivided, in the honours grade, into " Felegraphy" and "Telephony," and the latter into "Flectical Instru-ments," "Electric Lighting" and "Dynamos, Motors, ments," "Electric Lighting" and "Dynamos, "See". The subject of "Mechanical Engineering" is simihas been increased by the addition of a syllabus of instruction in " Goldsmiths' Work," in which subject a large class has been already established in Birmingham, and of a syllabus in "Ship Carpentry and Joinery, intended to meet the requirements of artisans engage 1 in the different shipbuilding yards throughout the country

The continuous increase in the number of candidates for these examinations, and in the number of students receiving instruction in the different centies throughout the country, shows that there is a genuine demand among artisans for practical and concrete instruction dealing, in the first place, with the facts with which they are familiar in their every-day work, and, afterwards, with the scientific principles explanatory of those facts. From the table found on p 17 of the Programme, it appears that this found on p 17 of the Programme, it appears that this year 7322 candidates presented themselves, as against 6667 in the previous year, and that the number of students under instruction increased from 12,022 to

13,202
The memorandum issued to County Councils, to which we have already referred in these columns, is ie published in the Programme It draws the attention of County and Borough Councils to the fact that, after the examination in May 1892, the grants hitherto paid on the results of the examination will be withdrawn, and that a sub stantial portion of the funds thus set free will be devoted to the improvement of the machinery of the Indications of the direction in which examinations these improvements will be made will be found in the new Programme It is important that the managers of technical classes should fully understand that, in future, the maintenance of such classes will depend entirely on local support The large sums placed at the disposal of County Councils clearly render it no longer necessary that the City (suilds Institute should continue to make grants on results, which, although amounting in the aggregate to a large sum of money, proved to be quite inadequate to properly support the classes. It is, however, to be feared that the grant-earning tendency of the teachers and managers of local schools may cause the distinctly technological subjects of instruction to be neglected for the sake of science subjects by which grants may still be obtained from South Kensington To prevent this, it is necessary that County Councils should realize the full importance of the work which Parliament has thrown upon them, and should recognize that in future they will be the authorities responsible for the conduct of the technical and, indeed, the secondary education also of the county. In the competition for money grants, technical subjects will be placed at a distinct disadvantage as compared with ordinary science subjects, and it is the more necessary, therefore, that the teaching of these

subjects should receive adequate support from local authorities

In order that the teaching in different localities may be duly adapted to the trades practised in those localities, and may be regulated by these requirements, and not by the grant-earning capacity of the subjects of instruction, it is very desirable that County Councils should organize. independently, or in connection with the City Guilds Institute, a system of inspection of local classes value of examinations is immeasurably increased when they are supplemented by inspection by competent experts, and it is to be hoped that some system of inspection of technical schools, which shall include the methods of instruction adopted, will soon be organized.

The Institute's Programme offers to different localities.

a wide choice of trade subjects, ranging from simple handicrafts to industries involving some of the most difficult applications of physical and chemical science To the syllabus of each subject is added a valuable list of works of reference, which forms by itself a very complete guide to books in technology. The list of examiners. many of whom have this year been newly appointed, includes well-known experts in each branch of trade, and is a guarantee of the efficiency of the examinations.

The future development of technical education is now very largely under the control of County Councils They possess the funds without which no real progress can be But, besides funds, experience and organization are needed, and there can be no doubt that the members of County and Borough Councils will derive much valu able information, and many serviceable suggestions, from the new edition of the City Guilds Institute's Programme of Technological Examinations

BOTANICAL SURVILY OF INDIA

THE organization of a Botanical Survey of India. which has been under consideration since 1885, has been finally settled by the following resolution of the Covernment of India, dated Calcutta, February 26, 1801 -

(1) The scheme for carrying out the botanical survey of India, which has been under consideration for some time, was finally completed a year ago, and His Excellency the Governor-General in Council considers that it is now desirable to publish the details for the general information of local Governments and Administrations

(2) In February 1885, Mr Thiselton Dyer, Director of the Royal Cardens at Kew, prepared for the Government of Madras a Memorandum on the constitution of a Botanical Department for the Madras Presidency, one result of which was the eventual establishment of a Botanical Department for that Presidency In sanctioning the Madras Department, the Secretary of State for India took the opportunity to suggest for the consideration of the Government of India whether, without interfering with the control exercised by the Provincial Governments, it would not be possible to bring into communication the various Botanical Departments of the different Provinces, the desirability of such an association having been promiently noticed by Mr Thiselton Dyer in his Memorandum of February 1885 The wider in his Memorandiim of February 1885. The wider scheme thus suggested by the Secretary of State was accordingly considered; and the first step taken for the organization of a Botanical Survey for all India, which was to have its centre in the Royal Botanical Gardens at Seebpur, Calcutta, was the transfer from the control of the Government of the North Western Provinces and Oudh, to that of the Government of India, of the Superintendent of the Botanical Gardens at Saharanpur measure was demanded by the need for botanical survey in the Punjab, Rajputana, Central India, and the Central Provinces, which had hitherto been unrepresented by any

botanical officer, as well as by the necessity for having a botanical officer at the disposal of the Government of India to accompany military expeditions beyond the frontier Arrangements were then made, with the concurrence of the local Governments concerned, under which the follow-

ing territorial division of India was prescribed for the

purposes of botanical survey — Under the Superintendent, Royal Botanical Gardens, Calcutta - The Provinces of Benyal, Assam, and Burma, the Andamans and Nicobars, North-East Frontier Expe-

Under the Government Botanist, Madras -The Presidency of Madras, the State of Hyderabad, the State of Mysore

Under the Principal, College of Science, Poona - The

Presidency of Bombay, including Sind
Under the Director, Bolanical Department, Northern
India—The North-Western Provinces and Oudh, the

Punjab, the Central Provinces, Central India, Rajputana, North-West Frontier Expeditions The distribution above stated was reported to Her Majesty's Secretary of State, and his Lordship has been

pleased to express his satisfaction with these arrangemente

(3) The Government of India now desire to communicate the following observations as to the central position which, in conformity with the suggestions of the Director of the Royal Botanical Gardens at Kew, the officer at Seebpur will occupy in the scheme for the botanical survey of India, and as to the sphere and nature of duties of each botanical officer, so far as they are connected with botanical survey

It is desirable that the Seebpur Institution-which, as remarked by Mr Thiselton Dyer, "though technically Provincial, must, at any rate in external estimation, from its age (it has passed its centenary), from its scientific traditions, and from the splendour of its maintenance, rank as Imperial "—should, without any interference with the Provincial control over the Royal Botanical Gardens, be officially recognized as the acknowledged centre of the Botanical Survey of India, and that to it should be referred the solution of all problems rising out of the practical or scientific study of Indian botany. In view of the important position which the Superintendent of the Royal Botanical Gaidens, Calcutta, will thus occupy as the central authority in the Botanical Survey of India, the Government of India have, with the concurrence of the Secretary of State, added to Dr King's present designation the official title of "Director of the Botanical Survey of India," and it is requested that in all correspondence dealing with subjects relating to general botanical exploration the latter title should be employed. The more effective botanical survey of Birma and Assam has also been intrusted to the Director, who will arrange a definite programme each year for the purpose in com-munication with the Chief Commissioners of those Pro-He will also submit a separate Annual Report on the botanical exploration and researches effected during the year. The Government of India record with satisfaction that the local Administrations of Burma and Assam have each contributed an annual grant from Provincial revenues as an addition to the Imperial grant for the botanical survey of their provinces.

The investigation of the flora of the Madras Presidency and of the Hyderabad and Mysore States has been in-trusted to Mr. M. A. Lawson, the Government Botanist and Director of Cinchona Plantations, who has expressed his opinion that the whole survey of the territories in question might, if diligently prosecuted, be completed in three or four years

In Bombay, a scheme involving an annual expenditure of Rs. 4500 per annum on botanical work has been sanctioned and Dr Cooke, Principal of the College of Science, Pouta, is officially recognized as in charge of

botanical research in that Presidency. A herbarium exists at the College of Science, and a botanical collec-tion is in course of formation at the Victoria Gardens, Bombay The former place is to be the head-quarters of botanical research and collections, and the existing herbarium there is to be developed

By the transfer of the services of the Superintendent of the Government Botanical Gardens, Saharannur-who now bears the designation of Director of the Botanical Department, Northern India-the services of this officer are, as already explained, available for scientific investigation in all Provinces and States in Northern and Central India, as well as on expeditions beyond the north-west frontier Mr. Duthie, the officer now holding the appointment, was thus in 1888, by his deputation to accompany the Black Mountain Expedition, enabled to acquire in-formation concerning the flora of a country which had not hitherto been botanically explored. During the last three years, Mr Duthie has also been deputed to Simia in the hot weather to assist in the preparation of the "Dictionary of the Economic Products of India," and during the same period he has been engaged in the botanical exploration of Rajputana and of the Central Provinces.

M. FAYE'S THEORY OF CYCLONES

N his admirable work on "The Principles of Science." I the late Prof Jevons thus sums up the characteristic mental attributes of the great scientific discoverer .—

"He must be fertile in theories and hypotheses, and yet full of facts and precise results of experience. He must entertain the feeblest analogies and the merest guesses at truth, and yet he must hold them as worthless full they are verified in experiment. Where there are any grounds of probability, he must hold tenaciously to an old opinion, and yet he must be prepared at any moment to relinquish it when a single clearly contra dictory fact is encountered "

In his theory of cyclones, M Faye has abundantly proved himself to possess those attributes that are defined in the first phrase of each of these sentences, and particularly the final one Whether, however, in his treatment of this subject, the manifestation of the remaining and qualifying attributes is equally recognizable; whether he has fairly grasped and duly weighed all the established facts that are relevant and even essential to his hypothesis; and whether, among those that he has overlooked, there are not some that are "clearly contradictory' to the re-quirements of his theory, and therefore fatal to it—these are the questions that I propose to inquire into in the present article

A true theory of cyclonic storms has not merely a scientific interest, it has also practical bearings of very high importance When a ship is involved in the outer circle of a tropical cyclone, the vital problem which the seaman has to solve is, how to escape the fearful squalls of the inner vortex and the tremendous cross-seas of the central caim. In order to do this he must be able to judge of the bearing of the storm-centre from the actual position of his ship, and, to determine this point with even approximate accuracy, his sole guide is the direction of the wind It may well be, then, that the safety of his ship, his own life and those of his fellow-seamen, are involved in the right answering of this question, "Does the storm-centre bear at right angles to the local direction of the wind, or is it from two to four points in advance of this position?" M. Faye's theory assumes and inculcates the former; the latter is consistent only with the hypothesis of an indraught from all sides, and an ascending current over the storm, the existence of which M Faye persistently denies.

M Fave's views on the nature of cyclonic storms are

too well known to render necessary any detailed descriptoo well known to render necessary any detailed descrip-tion of them. An account given by Mr Archibald in vol. xxxviii. of this journal (p 149) is quoted without dis-approval by M Faye in his latest publication in the Complex rendus, and may therefore be accepted as just Its essential points are that cyclones are generated as great eddies in the higher regions of the atmosphere, and that there is a downrush of air in the vortex "Dans ces tourbillons, tout semblables à ceux qui se forment dans les cours d'eau, les spires, d'abord très larges, iront en se rétrécissant par en bas, et leur girations progressivement accélérées, en vertu d'une loi bien connue de mécanique, amenent au contact du sol, et y concen-trent sous une aire bien plus étroite que celle de leur embouchure les énergies continuellement renouvellées du fleuve aenen jusqu'à ce que son clargissement croissant aboutisse à la décomposition du cyclone "

Further on, with respect to the descending current in the vortex, he remarks "L'air envoyé en bis sera en petite quantité mais animé d'une vitesse de rotation

ćnorme.

I leave aside for the present any criticism of the physical and mechanical actions which M Fave conceives to take place in these unfortunately inaccessible vortices of the higher atmosphere, and which I, for one, am unable to reconcile either with the results of direct observation or with well-established physical laws. For the moment I wish to concentrate attention on the question of fact, whether there is an indraught of air to the cyclone vortex at the earth's surface, and therefore necessarily an ascending current over it, or, on the contrary, an outflow from a descending current This is the crucial point of from a descending current. This is the crucial point of the controversy, and by the answer M. Faye's theory must stand or fall. Indeed, M. Faye seems to recognize this, since he says -

"L'argument le plus solide, celui qu'on m'opposait toujours nour prouver que l'air était ascendant dans les cyclones, à savoir le fait que les isobares étaient partout et toujours coupés sous un angle assez notable par les flèches des vents, de manière à accuser une tendance

nettement centripète, &c "

He admits, too, that in certain cases there is really an indraught and ascent of air; only, on his view, these are not cyclones

In order to forestall any objection on this score, I will take as the subject of inquiry the cyclones of the Bay of Bengal, the typical cyclones to which Mr Piddington first applied the name, however etymologically incorrect I trust, by this restriction, to escape ignominious dismissal from court on the plea that my witnesses are impostors—merely "prétendus cyclones"—and that their evidence

is consequently irrelevant.

My first experience of a great tropical cyclone was the memorable storm that devastated the port and city of Calcutta on October 5, 1864 Up to that time, my acquaintance with cyclones was, like M Faye's, "academic"; and under the impression that Reid's and Piddington's description of the winds, as blowing in circles or at right angles to the radius vector of the vortex, was an established scientific fact, on the evening of that day I sketched out, for the information of some friends, the probable course of the storm that was then passing away, having swept the port of its shipping, and left half the nouses around us more or less wrecks. Having no other guide at the moment than the changing directions of the hurricane as experienced at Calcutta, on the supposition that the centre lay at right angles to these directions, I inferred that the storm had reached us from the northeast corner of the bay, and had followed a north-west or west-north-west course past Calcutta. What was my surprise, then, when accounts began to come in from other places in Bengal, showing that the course of the storm had been almost due north; and when, further, on plot-ting down the wind directions reported from other sta-

tions according to the hours at which they had been observed, I found that, instead of being at right angles to the radius vector, they were strongly inclined inwards; and such as, after making all allowances for their being only estimated directions and perhaps, therefore, a point or two in error, could be reconciled only with a sharp spiral indraught to and up to the central calm. Later on, when I obtained copies of the logs of ships that had been involved in the storm in its passage up the bay, I found that their wind observations, equally, were compatible only with spiral directions Unlike M Fave. I had no theory to support, and I submissively accepted the teaching of the evidence which lay so plainly before

This evidence is set forth on Plates I and II, of the Report drawn up by Colonel Gastrell and myself, which was widely distributed at the time to scientific bodies, so that, in all probability, a copy must exist in the library of

the Académie des Sciences

Since then, many other storms in the Bay of Bengal have been carefully investigated, and their full details embodied in Reports drawn up by Messrs Wilson, Eliot, Pedier, and myself Without a single exception, the evidence thus accumulated has been to the same effect as that of the cyclone of 1864, and these gentlemen have all arrived at conclusions similar to mine Thus, Mr Wilson says1 .- "The following rule may be used to determine the approximate bearing of the centre with as much accuracy as it seems to be possible to arrive at In the northern hemisphere, with the face to the wind, the direction of the centre is from ten to eleven points to the right-hand side", and, to quote only one of Mr Eliot's numerous references to this subject,? "The air is drawn into the centre [of a cyclone], but is not drawn directly to it. The particles move by a kind of spiral And he gives a diagram, followed path to the centre " by charts of the Balasoic cyclone of May 1886 and the Madras cyclone of November of the same year, as illustrative examples And Mr Pedler, in summing up the evidence of the False Point cyclone of September 1885.

says 3 — "It is therefore clear, from these autographic records, that there was a very strong indraught towards the storm-centre, and that for a considerable portion of the time, even when the storm-centre was comparatively close to Hazaribagh, the winds were part of a well-defined spral system. In fact, for a large part of the time they subtended an angle of less than 45° with the radius of the storm.

The records of five anemographs within the influence of the storm . show that the theory of the circular movement of winds in a cyclone, which was advanced by Reid and Piddington, and has been supported by some later writers, is utterly untenable considerable distances from the storm-centre the winds approach more to the radial direction of indraught towards the centre, as advocated by Espy, than to any circular movement. As the centre of the storm is approached, the circulation appears to become more defined; but even just outside the storm-centre there is no evidence to show that the direction is tangential "

The reports here quoted and many others, all leading to the same conclusions, have been communicated officially to a large number of scientisic bodies in Europe and elsewhere, and taken together they probably furnish the most copious and complete body of existing evidence relative to the cyclones of a tropical sea. Not long since I examined the whole of the charts given in these reports, in order to verify Mr. Wilson's rule (quoted above) for ascertaining the bearing of the storm-centre when th

[&]quot; "Report on the Midnapore and Burdwan Cyclone of October 15 and 15, 1864," p. 86 The trainer are as as the original Report." p. 14,1860.
3 "Indian Meteorological Memora," vol. 1, Part. 2, p. 37. The harometric passing seconded when the centre of this vious was passing kilose Douts Lighthouse is the lowest that has ever been observed at the sea-level

local wind direction is the only datum available, and I found that in the north of the Bay of Bengal, as the mean result of 132 measurements, the angle included between the wind arrow and the radius vector of the vortex was 122" (or 32" greater than a right angle), and that of twelve positions within 50 miles of the storm-centre, that is to say, in the inner circle of the hurricane, 123° In the south of the bay it was 7° greater. Prof Loomis, taking into account the land as well as the marine observations, and all barometric depressions, whether storms or otherwise, obtained an angle 25° greater, and dif-fering only by 33° from the radial direction. It is hardly necessary to refer to Prof Loomis's results of his examination of the Manilla cyclone of October 1882, which gave an angle of 1183, or to Mr Meldrum's work on the cyclones of the South Indian Ocean, which has already been quoted by Mr Archibald in his article in NATURE, mentioned above. All testify uniformly and in the strongest manner to the sharp spiral indraught of the winds in tropical cyclones, so that, as Prof Loomis has truly remarked, "we thus see that tropical storms are spouts and not cyclones, and it is unfortunate that the spouls and not cyclones, and it is unortained and the term cyclone should have been ever adopted. In this view I fully agree, and I make M Faye a present of the admission, that in an etymological sense, if in no other, Mr. Piddington's typical cyclones are not cyclones at all.

With all these results of a quarter of a century's expersence present to my mind, when a gentleman holding the high position of M. Faye resterates the assertion that the winds of tropical cyclones blow in circles, and that if ever they are found to blow spirally inwards such instances are not true cyclones (in the ordinarily accepted, i.e. denotative, meaning of the term), the impression I receive is somewhat such as M Faye would probably experience were some equally eminent scientific authority to assert in his presence that the Ptolemaic system truly represents the relative movements of the sin and planets, and that the heliocentric scheme of Copernicus is a "prétendu système." If, indeed, M Faye prefers to avail himself of the admission made above, to relegate Mr Piddington's typical cyclones to the category of "prétendus cyclones," and therefore to exclude them from his theory, my present argument falls to the ground, but in that case his cyclone becomes the mere abstract definition of a term, and it remains to be shown that there is anything corresponding to it in Nature That, however, in his latest communication to the Comptes rendus, he intended his assertions to

apply to these tropical cyclones is abundantly apparent
Can it be that M. Faye is unacquainted with the mass
of original evidence embodied in the Indian cyclone reports, in Mr Meldrum's writings on the cyclones of the South Indian Occan, and with Prof. Loomis's work, in which these and many others are discussed? It would indeed seem so, since in none of his writings have I ever seen any reference to any other Indian author than Mr Piddington, and even in his case it is difficult to believe that M Faye has done more than simply accept Mr Piddington's conclusions, without attempting to verify them by an examination of the original data. But if this But if this be really the case-if he has taken so little pains to ascertain the fundamental facts, and to test the soundness of his speculations by an appeal to the evidence of the last twenty-five years-it is indeed strange that he can put forward confident assertions on a matter with which his acquaintance is so imperfect, and that he can disseminate statements that are demonstrably erroneous, and may be fraught with danger to the lives and property of those who accept him as their guide, backed with the high authority that must necessarily attach to his name

It is a far from edifying spectacle to see such a man, in his latest communications to the Comptes rendus, quoting with complacency any isolated passage in the writings of leading meteorologists which seems to promise some

would tell against it. That such cyclones as originate beyond the tropics are, in the first instance, movements of the higher atmosphere, has been rendered very probable by Dr Hann's demonstration of the temperature relations of cyclones and anticyclones, but nothing that Dr. Hann has ever written has shown that he is in the least inclined to accept M Faye's strange hypothesis of a descending current as the leading feature of cyclones and tornadoes That the clearing of the skies in the central calm of a tropical cyclone may be due to the descent of a certain amount of air, although not decisively proved, is yet not improbable; but what would be thought of a man who, standing on a river bank, and seeing an upward current in the back-water immediately below him, should shut his eyes to the broad stream beyond, and assert, on the strength of his observation, that rivers flow from the sea to the mountains? Yet such, and no other, is the relation of this descending current to the great body of the cyclone All may admit, with Prof von Bezold, that there is much in the views hitherto prevalent as to the origin of cyclones and anticyclones that requires modification, and it may yet be long before these phenomena are fully and satisfactorily explained. There are many points of difference between the storms of the tropics and those of the temperate zone which seem to show that the forces that are principally active in the former play but a secondary part in the latter certainly there is no apparent tendency on the part of the leading meteorologists of Europe and America to accept M. Faye's tdolon specus as a true theory of cyclones and tornadoes, nor is it in the least likely that such will ever be witnessed HENRY F BLANFORD

NOTES

I HI Alreagements for the meeting of the British Association are now nearly complete. In a former note we referred among other matters to the exensions. We now learn that among them the organization of the pedestrian excursions to the Black Mountains is so far advanced that the detailed programme is now ready, and can be obtained by application to the Local Secre-

THE Royal Archeological Institute of Great Britain and Ireland opened their annual meeting in Edinburgh on Tuesday. At noon there was a reception of the members in the National Portrait Gallery by the President and Council of the Society of Antiquaries of Scotland The inaugural meeting took place in the lecture hall of the Royal Geographical Society Sir Herbert Maxwell, on taking the chair, remarked that the closing years of a century naturally suggested the process of stocktaking, and as they had arrived at the last decade of a century which claimed to have witnessed beyond all precedent the accumulation of scientific knowledge, it was not unnatural that they should direct inquiry into the standing obtained by that particular branch of science in which they were all concerned After a brief summary he stated that one of the problems which was pressing upon antiquaries at the present time was that relating to those mysterious rock sculptures which from time to time were found in increasing numbers all over Scotland They bore a striking resemblance to similar rock sculptines found not only in Scandinavia and Central Europe, but in such remote parts of the earth as Asia, and Northern, Central, and Southern America. They could hazard no guess even at the race by whom they were made, still less at the object of their authors. All they could do was to record the discovery of them with careful drawings, and wait till perhaps light would flash upon them from the habit of some uncivilized support to his toltering theory, and ignoring all that tribe or from a passage in some hitherto unnoticed writer. In the evening Dr. John Evans opened the Antiquarian Section with an address on the progress of archieology. The address covers the whole ground from Christy and Lartet's researches on the Dordogne to the Assyrian tablets.

By an Imperial Decree of June 8, the Gold Medal for Art and Science was bestowed by H I W the Emperor of Austria on Dr. R Bowdler Sharne, of the British Museum

At the graduation ceremony of the University of Edinburgh, held on the 1st int, the Cameron prize was presented to Fir. Ferrier, F.R. S., by Prof. France. Prof. France sud that Dr. Ferrier's researches had gaused for han a well mentied fame throughout the whole cruised world. He had contributed to the allevation of suffering in some of its most distressing and panful manifestations, and therefore the Senates had thought that they were fully justified in awarding to him the prize, which had been founded for the recognition of important and valuedic contributions to practical their passes of the pleasure in announcing further that Dr. Ferrier would, early necessarily mentioned the present sensing the prize of the professional properties of the prize o

AT a meeting of the Academy of Medium of Parts on the 28th alumo, Sr Joseph Fayer, of I ondon, and Dr. Batenan, of Norwah, were elected Associates of the Academy These gentlemen had both been for some years Correspon lang Members of the Academy, but they shared the Membership with only six other members of the profession in this country, vz. 's 'I' prince Paget, Bart, Sr Richard Owen, 'sı Joseph Hooker, 'sir Thomas Longuone, Dr West, and Sır Speace Welst, Burt

DR THORNE THORNE, F R S, has been elected a Corresponding Member of the Royal Italian Society of Hygiene.

PROF DU BOIS REYMOND has been elected Dean of the Medical Faculty of the Berlin University for this year. He has already more than once filled this post. Prof. Foerster, the astronomer, has been chosen Rector of the University

HER MAIRSTY's Commissioners for the Exhibition of 1851 have offered nomination to Science Scholarships for the year 1892 to the following Universities and Colleges The Scholarships are of the value of £150 a year, and are tenable for two years The scholars are to devote themselves exclusively to study and research in some branch of science the extension of which is important to the industries of the country - University of Edinburgh, University of Glasgow, University of Aberdeen, Mason College of Science, Birmingham , University College, Bristol, Durham College of Science, Newcasile, Yorkshire College, Leeds, University College, Liverpool, Owens Col lege, Manchester; University College, Nottingham, Firth College, Sheffield, University College of North Wales, Bangor , Queen's College, Cork , Queen's College, Galway , University of Toronto, University of Adelaide, University of New Zealand.

In has been decided to perpetuate the memory of the connection of Dr. Leidy with the University of Pennsylvana by raising a find to endow the Chair of Anatomy and to found a memoral emission. Dr. Leidy was Professor of Anatomy for thirty-nine years, and his devoted services will be suitably recognized by connecting his name with the chair which he so long adorned.

THE arrangements for the World's Fair at Chicago seem to be advancing quickly. Seeing that so much benefit to cience may be anticipated from the comparison of the best instruments and methods of working in use in different countries, which

such exhibitions render possible, it seems a pity that political questions may render them less representative than might be wished. The New York Nation refers to the reluctance of French manufacturers to take part in the World's Fair, due to the bad feeling created by the McKinley Bill, and to the belief entertained that any expense incurred in exhibiting good, would be lost by reason of the commercial re-trictions which that measure was intended to create and his created. "Nobody cares to spend his money for mere purposes of show. Unless trade follows as a consequence of the exhibition, the money will be sunk. . It does not advance matters, or help on the Fair, to show that both countries are wedded to a faise system It should serve, however, to open the eyes of people on both sides to the absurity of inviting each other to show their goods, and then creating barriers to prevent each other from buying and selling. Imagine an American McKinlevite meeting his French brother at a World's Fair in Paris or in Chicago, and exhibiting to the latter a choice lot of provisions put up in Mr Annour's most approved style, while the latter exhibits a fine assortment of woollens, silks, gloves, &c. If they could look in each other's faces without laughing, they must have a gravity exceeding that of two Roman augury. Ordinary self respect ought to teach the commercial classes of both countries to keep away from World's Pairs until they learn the A B C's of trade "

l'eclinical instruction in the provinces is F pur a muse growing apace, smill thanks to our state-men and legislators, for we one to an accident the possibility of meting the met crying needs of the time We may refer to what is going on in Lancashire as an indication of the general awakenment The total sum available for technical ins auction is £40,391, and, after the sums afready guar inteed by the County Council and some special amounts now in question are taken into account, there is a balance of about 1,29,000 to be dealt with, which the committee of the Council recommend should be apportuned between the urban and rural districts of the administrative county on the dual basis of rateable value and population. The committee recommend that a director of technical instruction be appointed at /500 per annum, with travelling expenses, that £3600 beset abait to provide twenty scholarships not exceeding 4.60 each for a term not exceeding thice years, apportioned as follows-eight for science (tenable at Owens College, Liverpool University College, or other approved public institution), two for art, four for commercial subjects, and six for the science of agriculture, including horticulture, that £1200 be set apart for providing eighty exhibitions of (15, tenable for one year at Owens College and I iverpool University College evening classes, or at some approved technical, commercial, or intermediate school, to be apportioned as follow--thirty two exhibitions for science, eight for art, sixteen for commercial subjects, and twenty-four for agriculture, that £2000 be set apart for founding travelling scholarships and free studentships of £1 to £10 to assist students in attending technical schools, that the various urban and rural sanitary authorities, through or in conjunction with any district committees that may be appointed, be permitted to nominate candulates for the above, two thirds of whom shall be children of parents whose incomes do not exceed £300 per annum, that all the scholarships and exhibitions be opened to students of both sexes resident in the county, that a sum not exceeding £1000 be granted for the purpose of aiding University Extension lectures, that a sum not exceeding £500 be granted to carry out the arrangements with the council of the Harris Institute in Preston for the promotion of technical instruction in agriculture, and that a sum not exceeding £ 1000 be granted for staff and office expenses. The migratory dairy school having been much appreciated, arrangements have been made to start a second school at Ulverston on August 11. A scheme for agricultural

instruction is also being arranged (estimated to cost £500 per annum), but the details have not yet been finally settled.

THE managers of the New Gallery announce a "Victorian Exhibition," covering the fifty years of Her Majesty's reign from 1837 to 1887. As in the case of the preceding exhibitions, it will contain pictures and other records of events illustrating the history of the Royal Family and of the nation, and it will contain, above all, a series of portraits of the illustrious men and women who, in so many different ways, have made their mark upon the age We gather from an article in the Times that science, in this of all reigns, is not likely to fall behind. We are promised pictures of Charles Darwin, Faraday, and Sir John Herschel, of Lyell and Murchison, of the two Stephensons, of Fox Talbot, one of the inventors of photography, and of Wheatstone, one of the inventors of the telegraph. The article adds that "it would be easy to quadruple this list, supposing the eminent men of science to have had the time and the vanity to sit for their portraits." We agree

THE Pall Mall returns to the charge on the subject of the imagined unpopularity of the British Museum, and states that although the evening openings have so far been a failure, and a very costly failure, the first installation of the electric light costing over £17,000, the problem is being carefully considered It is also stated that it is an open secret that for some years past the Trustees have been unanimous in favour of Sunday opening. which, as they have more than once pointed out, would entail little or no extra work on the officials, but merely change of work for a few policemen. Among the things that are wanted are certainly continuity in the hours during which the Museum is open on any one day, and the possibility of obtaining some decent refreshment If in these matters the Trustees will imitate he arrangements at the South Kensington Mureum, we believe the attendance will be increased-the attendance of workers certainly will

We are requested to state that the designs submitted in competition for the completion of the buildings of the South Kensington Museum are now on view at that Museum from 10 till 6.

DURING the whole month of July little variation to the state of Vesuvius was observable; the lava flowed steadily on, and had at one time extended down the Fossa della Vetrana, nearly opposite the lodge and gate of Messra. Cook's private road to the Vesuvian railway, but immediately cooled, and again started flowing much nearer its source At the summit of Vesuvius the vapour appeared to issue almost as in the normal state of the mountain, except for momentary interruptions and occasional ejection of dust and sand Dr Johnston Lavis, who has recently visited the scene, sends us the following details -"On July 30, I again visited the top of the great cone. The central crater has considerably enlarged, and has now an elliptical plan, with the major axis directed north west to south east, but this form has been derived from its original circular shape by the greater destruction of the lips towards the south east. The edges were in a most unstable state, and attempts at photographing the interior were accompanied by considerable danger, and required many precautions On the inner walls I was, however, able to make out several dykes besides the hollow one that has supplied the great eastern rift for its several eruptions from 1881-82 to 1890. These may be enumerated as directed north-east, north north-west, probably the dyke formed at the commencement of this eruntion . north-west, south-west, probably the cooled upper extremity of the lava sheet filling the south-west fissure which I have so often mentioned; and lastly, the hollow dyke to the south-south east. which supplied the lava of May 1885, is again exposed. There may be other dykes, but the large amount of vapour filling the crater, and the danger and impossibility of approaching the

edges in most parts, prevent a very detailed examination. So far a I could make out, the situation of the vent is quite to the south-east of the erater bottom, so that this fact, combined with the prolongation of the crater in that direction and the existence of numerous radial fisures, would indicate that the epistence of numerous radial fisures, would indicate that the general tendency is for the next lateral disraption to take place towards Pompen, or Torre Annanatia. On July 30 the laws was flowing very slowly just at the junction of the Atrio del Cavildo and the Fossa Verrana. To an experienced observer the whole state of the mointain is still very untable, and a fresh outbard might occur at any moments, shough the voto from any greatest proteam of the control of the control of the control of the were felt at the lower rallway station, showing that inportant fraduring, injection, or other dynamic disturbances were taking place in the great cone,"

WE have received from Mr C Mostyn an interesting letter on the well known appearance of the green ray at sunrise or sunset caused by the refraction of the air He states -"This 'green ray' is seen to best advantage at sun rise, owing I imagine to the eye not being wearied with watching the previous glare, as is apt to be the case at sunser At the same time, I had many very satisfactory observations at sunset, one in particular, when we were running before a very heavy sea in the Southern Ocean, and the 'green ray' was seen no less than three times in as many seconds, as the ship rose and fell on the huge waves causing as it were two sunsets, with a sunrise between them The best displays took place when the refraction near the horizon way of such a character that the sun assumed a balloon, or vase, shape as he came close to the sea-line When, on the contrary, the sun appeared flattened out in its horizontal diameter, the green ray was cuther entirely absent, or was seen only in an indistruct and uncertain manner "

SIE FIWARD WATKIN having now, we pressume, cured unpontenshity on the many lines of railway which he is highly paid to manage, is aguin turning his attention to Snowdon. It will live be remembered that he proposed in the first instance to erect an astronomical observatory there. This, of course, was relictions, we are now told that the authorities of the Timity House have expressed warm approval of his more recent proposal to place an electric light on the summit. The Filder Brechric consider that the light should prove an invaluable addition to those already erected round the North Wales coact for the guidance of manners. Six Fidward hopes to have the light burning before Christ max.

Titte Directors of the Crystal Palace, in deference to the wish of the Leterical Trade Section of the London Chamber of Commerce, have decided to postpone the opening of the Elec trical Exhibition from November 1891 till January 1, 1894, on which date the Exhibition will be formally opened.

WE learn from the Photographic News that the great progress that has been made in the methods by which rapid movements can be analyzed is well seen in a series of photographs lately taken by Anschutz, of Lissa, who has already given to the world some of the best instantaneous pictures ever taken. The subject of the pictures at present under consideration is a dog jumping over a small bush. In the act of making one jump the animal has been photographed twenty-four separate times, and each picture is not a mere silhouette, as was the case with Maybridge's first attempts of this kind, but a little picture showing half-tone and detail Some of the attitudes are, of course, comie in appearance, for they represent phases of a movement which the eye is unaccustomed to, and cannot possibly appreciate. Notably is this the case in the commencement of the jump, when the dog's hind toes only touch the ground, and again at the finish of the jump, when his legs are gathered together in a

A GEMAN specialat, Dr. Cold, has recently yleaded for gyring young propile more sleep. A healthy minat sleeps most of the time during the first weeks; and, in the early years, people are disposed to let children sleeps as much as they will. But from six or sween, when school begins, there is a complete change as or sween, when school begins, there is a complete change hours, when he needs at least ten or eleven, and as he grows older the time of erest is shortened. Dr. Cold believes that, up to twenty, a youth needs mue hours' sleep, and an adult should have eight or nine. With insufficient sleep, the nervous system, and brain especially, not resting enough, and ceasing to work mortally, we find exhaution, excitability, and intellectual disorders gradually taking the place of love of work, general well-being, and the spint of instative.

THE Entomologist's Monthly Magazine, among much interesting matter, refers to the possibility of the destruction of some of the inclosures in the New Forest which have proved themselves to be among the happiers hunting-grounds of the entomologist

A REENT number of the Proceedings of the Academy of Natural Sciences of Philadelphia contains a paper on Echino derms and Arthropols from Japan, by Mr. J. E. Ives. The specimens described were collected by Mr. Frederick Steams, of Deroit. The new species of Echnoderms and Crustaces are enumerated. A new Opharima, a new cuts, and a new Pyenogonoid are described, and several species of star fishes their outsign and are illustrated. The places are admirable

BULLETIN No. 10 of the University College of Agriculture at Tokyo contains an account of some manuring experiments with paddy rice (second year) by D. O. Kellner, Y Kozai, Y Mort. and M Nagaoka. The principal purpose of the researches carried out in 1889, and reported in Bulletin No. 8, was to ascertain how much nitrogen, phosphoric acid, and potash can be consumed by rice from the stock of nutrients in the unmanured soil, and how much of them is needed in the manure for the production of a maximum crop if the three nutrients are applied in the most assimilable form. On the basis of the results then obtained, the present experiments were tried with the object of getting information on the following question: -(1) How much nitrogen, phosphoric acid, and putash is taken up from those plots which had not received the respective nutrients in the preceding year? (2) What is the effect of unrecovered phosphatic manure on the succeeding crop? (3) How much nitrogen can be supplied to rice by the preceding cultivation of a leguminous plant (Astragalus lotoides, Lam) for green manuring ? (4) What is the effect of various phosphatic fertilizers on rice? (5) What is the effect of various nitrogenous manures on rice? The work seems to have been carefully done, and affords a good instance of the way in which scientific questions are now being treated in Japan.

This July number of the Proceedings of the Society for Styphetal Research has reached us, and contains the following contributions —"On Alleged Movements of Objects, without Contact, occurring too in the Presence of a Pard Medium," by Mr. F. W. II. Myers, "Experience in Clairopance," by Dr. A Backman; and "A Case of Double Consciouspess," by Mr. R. Hodgwo.

At the Boursemouth meeting of the Bush Medical Association, a discussion on the subject of alcohol was immared by a paper by Dr. Samuel Wilks. In the course of his paper he stated that he had no acquaintance with anyogranic changes attribushel to alcohol in the lungs and kidneys, but it seemed that the digestive and nervous systems suffered "Physiologius had failed to demonstrate the chemical changes which it underwent in the body, and consequently it was impossible to say whether twas of the nature of a food or nor. No one had get seep a person who lived on alcohol, although there was evidence of persons taking large quantities of alcohol who yet preserved their weight with a minimum of food, and that supported the theory that, although alcohol was not nutritive in itself, it prevented the wear and tear of the body The opposite theory also existed, that alcohol acted as a spur to the nervous system and quickly wore it out. He could not disapprove of the use of wine and beer, if taken in moderation, by the masses of the people , but as to spirits or spirits and water, he had not made up his mind that they were in any way useful, and he seldom recom mended them. Dr Bucknill thought that the wise use of wine might cure some cases and be useful in others. Dr Norman Kerr said that alcohol was a poison, analogous in many respects to other poisons Sir Risdon Bennett agreed with Dr Wilk in not approving of spirits as a beverage lie believed it to be useful in fever and in some nervous diseases, but he did not think it desirable at the present time to lay down any broad principles with regard to alcohol with reference to the whole community

The Philadelphia Satellite states that, during the abortive attempt to cut a canal through the isthmus of Panama, as much as 200,000 ounces of quinne were used annually in combating malarial fever

ACCOUNTS to the Pharmacontual Tournat of Australus, the practice has been introduced into Victoria, on the recommendation of literon wor Mueller, of placing green branches of eucations of the property of th

THE Bulletin of the (American) Essex Institute just recrived contains an account of the annual meeting held la-t May, and a retrospect of the year, from which we learn that Mr Perley, in a lecture on "Old time Winters in Essex County," gave interesting particulars on many subsects, including weather. We give the following extract -"The lecturer spoke of the watch, church services, dres-, food, and schools of the early winter seasons, how the people spent their evenings, the winter employment of the people in cutting off the forest, sledding timber and wood, making pipe staves and barrel hoops, and, most interesting of all, the insutation of the old fashioned shoemakers' shops, of which nearly every farm had one a century 130 Women in those days engaged in spinning and weaving The holidays were referred to-Thanksgiving, Christnias, and New Year's , and the winter pleasures, such as sleigh-rides, dancing, spinning and quilting parties, and games, shuffle-board, coasting, skating, trapping, gunning, fishing, singing-schools, and girls' samplers He also spoke of the old modes of travel, snow slices, &c Nearly all the heavy teaming was done on sleds, and he mentioned the winter of 1768-60, when the travelling was so had that the farmers in the western part of the State could not get their grain and provisions to the coast to market Snow remained on the roads as it fell until about a century ago. Mr Perley then spoke of particular winters, that of 1641-42, when the Indian's said they had not seen the ocean so much frozen for forty years, of 1646 47, when there was no snow to lay, of 1696-97, said to be the coldest winter since the first settlement of New England; of 1701-2, which was 'turned into summer', of 1717-18, when the snow was from ten to fifteen feet deep and the drifts twentyfive feet, many one-story houses being buried, of 1740-41, said

to be the severest winter known by the settlers. Salem Harbour being frozen over as early as October, of 1774-75, a wonderfully mild winter, of 1779-80, when for forty days, including March, there was no perceptible thaw, and the snow was so hard and deep that loaded teams passed over the fences in any direction. arches being dug under the snow so that men on horseback could tide under them, and which was long remembered as the hard winter, of 1784-85, when, as late a. April 15, snow was 2 feet deep, and frozen hard enough to bear cattle, of 1785-86, when in the remarkable storm of November 25, the snow blew anto balls, one of which had rolled 76 feet, measuring 176 by 22 inches, of 1704-05, when the Betsey was launched in Salem on Christmas Day, the thermometer indicating 85° above zero at noon, and men and boys went in swimming , of 1801-2, when the Ulysses, Brutus, and Volutia, three Salem vessels, which sailed out of the harbour on a summer like morning in February. were all cast away at night on Cape Cod, in a terrible snowstorm, which continued a week. He also referred to more re cent seasons, and of the cold winter of 1856-57, when in one week in January was the coldest day by the thermometer ever recorded of late years, mercury in Salem 20° below zero : travel on the railroad between Boston and Salem entirely suspended from Tuesday morning to Thursday afternoon The recent mild winters were also alluded to "

IN the volume of Bayarian meteorological observations for 1800, Dr. C. Lang (the Director of the Service) contributes an article on the "Secular Variations of Damage by Lightning and Hail" He points out that in almost all recent investigations the conclusions come to are that during the last 50 years damage by lightning has much increased, but this is not borne out by his inquiry, but is probably owing to more attention having been paid to the subject recently. The numerous impurities introduced into the air of towns from hre-places, &c . would make it probable that they would be more liable to damage than country places, but exactly the opposite is the case, the ratio of damage to buildings in towns to that in the country being 1 2. This result is possibly to some extent due to the more numerous lightning conductors, and to railway lines in the towns He finds that the damage from hail shows a very probable connection with the period of sun spot frequency, but the secular range of the former points more particularly to the influence of temperature, so that the curve of hail-frequency shows, not only a minimum occurring with the II-year sun spot maximum, but also a period of about 35 years. The damage from lightning, on the other hand, does not show any connection with a secular range of temperature, but the minimum occurs with the maximum of sun spot frequency In other words, damage from hail seems to be more decidedly connected with terrestrial, and damage from lightning more with cosmical influence

THE application of science in the direction of domestic comfort scems to be advancing with great strides in the United States. The Nation, in ref. rence to the announcements that the inhabitants of Kansas City are about to be supplied with cool air in summer and warm air in winter through a system of pipes laid in the streets, and that the people of Framingham, Mass., are to be furnished with gas for heating purposes at the price of 50 cents a thousand feet, thus writes -" Thus the ends of the land are advancing in the art of living while the metropolis remains tationary, and is kept from falling behind only by incessant grumbling And yet the possibilities of comfort, of health, and even of cheapness revealed in these schemes are wonderfully alluring, and their realization would be prevented by no physical obstacles If we consider that wonderful work of human hands, the kitchen range, under the management of the regular cook, who knows how to put on all the draught at once and keep it on,

what aderourer of finel it is I. We need a cup of tex or a chop in summer, and a fire is kindled that would generate steam enough to drave an ocean nacer a unle upon her course, this kitchen is turned into a Tophet, the miscrable servants swelter in the apartments which their own stapidity and that of man-kind have rendered unnohmbathle, and their employers are rendered uncomfortable above. The extravegance of the Chinese, who, as related by Charles Lumb, at first thought it necessity to burn down a house whenever they wanted to roat a pag, an onting to ours." Has anybody ever calculated the annual watte caused by the above described "use" of the ordnary "kitchen range"?

An interesting paper upon the slow combustion of explosive gas mixtures is contributed to the current number of Liebig's Annalm by Dr Krause and Prof Victor Meyer The experiments described were made with electrolytic mixtures of hydrogen and oxygen, and detonating mixtures of carbon monoxide and oxygen. The first experiment consisted in heating in a bath of vapour of diphenylamine (305") a detonating mixture of hydrogen and oxygen contained in a U-shaped tube closed by mercury. The heating was continued without intermission for a fortnight, at the end of which time very little gas remained, almost the whole having slowly combined to form water. The experiment was then repeated in an apparatus constructed entirely of glass, and in which the use of mercury was avoided, except in a small manometer used to indicate the pressure. It was then found that no trace of water was formed at the temperature of diphenylamine vapour (305° C), at the temperature of boiling sulphur (448°) the amount of combination was exceedingly small; while at 518°, the boiling-point of phosphorus pentasulphide, a considerable amount of combination occurred, but no cusnititative rule could be deduced. In all these experiments the gases employed were most, and no particular care had been taken to remove the last traces of admixed air Now Bunsen and Roscoe, in their celebrated work on detonating mixtures of hydrogen and chloring, showed that regular results were only obtained when the film of air condensed upon the surfaces of the glass vessels employed was removed by allowing the gas to stream through the apparatus for several days previous to the experiment A fresh series of experiments were therefore made, in which these precautions were most rigidly observed a most complicated pieces of apparatus were constructed of glass throughout, which admitted of the drying of the gases prepared (in case of hydrogen and oxygen) by the electrolysis of hot water, so as to exclude ozone and hydrogen peroxide; and the pure gases thus obtained were allowed to stream through the series of bulbs united by capillary tubes for a fortnight, night and day, before the bulbs were sealed off at the capillaries. was found that, with pure dry gases, scarcely a trace of combination occurred by the fusion of the very fine capillaries As regards the temperature of ignition of electrolytic hydrogen and oxygen, or detonating carbon monoxide and oxygen, it was found that bulbs containing them do not explode when placed in boiling pentasulphide of phosphorus (518°), but do explode in vapour of stannous chloride (606°). The temperature of ignition lies, therefore, between 518° and 606° C The mode of explosion differs considerably under different circumstances. In case of explosion in vapour of stannous chloride, the bulb was never shattered, but a sudden appearance of flame within the bulb occurred, accompanied by a slight detonation, and in some cases the point of the capillary was blown off It is also astonishing how long one requires to hold such a bulb in a Bunsen flame before explosion occurs; it never occurs until the flame becomes coloured vellow, and the glass begins to soften, and frequently only causes a swelling out of the glass at the heated spot. Thinwalled bulbs, however, are sometimes shattered. In two cases it was noticed that the glass at the softened part was violently NATURE

forced in, owing to the previous heating having caused a large percentage of combination, and hence the production of a partial vacuum. Even after taking the rigid precautions to insure purity above described, no definite quantitative rule connecting the time and percentage of combination has been discovered, experiments performed simultaneously upon similarly treated mixtures yielding widely different results; showing that the irregularities of glass surfaces, even after removal of their airfilms, are quite sufficient to modify very sensibly the conditions under which combination occurs

THE additions to the Zoological Society's Gardens during the past week include an Egyptian Cazelle (Gazella dorcas) from North Africa, presented by Mr S C Stunders, a Ring-tailed Costs (Nasua rufa) from South America, presented by Mr Edward J Brown , two Herring Gulls (Larus greentatus). British, presented by Mr T. A Cotton, two White-bellied Sea Eagles (Hahatus havegaster) from Australia, presented by Mr Hugh Nevill, F & S. a Lesser Sulphur crested Cockatoo (Cacatua sulphurca) from Molucous, presented by Miss Partridge . three Barbary Turtle Doves (Turtur resoreus) from North Africa. presented by Miss D Bason; an Indian Cobia (Nata tripudians) from India, presented by Mr. H. F. Lindsay , two Hainessed Antelopes (Iragelaphus scriptus & 9) from Cambia, a -Paradoxure (Paradoxurus aureus) from Ceylon, two Giey Ichneumon (Herfestes griseus) from India, four grey Pairots (Psittacus erithacus) from West Africa, deposited

OUR ASTRONOMICAL COLUMN.

THE SPLCTRUM OF & LYR 1 -A study of twenty nine photo-THE SPECTRON OF BLYET —A SURY of twenty nine photo-graphs of the spectrum of B Lyra has led to some interesting results, noted by Prof E C Fickering in Astronomiche Nach-ichten, No. 3051 The spectrum of this star contains, in addition to the absorption lines, several bright line, the most conspicuous of which are about AA 486, 443, 434, 410, 403, and 389, to use a three figure reference. The lines near A 443 and 389, to use a three figure reference. The lines near A 443 and A 403, are two of the most promanent innes in the species of the Orion stars, and the remaining four coincide with the hydrogen lines; h. G. A. and a From the investigation it appears that these bright lines change their positions, so that sometimes they have a greater wave-length than the corresponding dark lines, whilst at other times the reverse is the case. In whilst at other times the reverse is the case. In some of the photographs several bright lines are double, and the dark lines are also not free from changes. This naturally led to the in quiry as to whether the changes were connected with the variations of the star's brightness. Starting from a minimum of tions of the stars originates statents from a minimum or brightness there is a maximum at 3d f.h., a secondary ninnmum at 5d 1th, another maximum at 9d 16h, and then the prin-cipal minimum is again reached after a total period of zdd zzh. The point of interest is that the fourture plates in which the secondary of the bright lines was increased were taken during wave-length of the prigot lines was increased were taken during the first half of this period of variation—that is, before the secondary minimum, whist on the eleven plates taken during the second half of the period the displacement was towards the blue end of the spectrum. And since the photographs extend blue end of the spectrum and since the photographs extend over more than four years, there can be fulled doubt that the displacements are intimately connected with the variations of the star's brightness One of the explanations suggested by Prof Pickering to account for the observed phenomena is that the bright lines are emitted by an object revolving in a circular orbit round the principal star, with a maximum velocity of about 300 miles per second, and completing its circuit in a period of 12d. 22h. The corresponding periastron distance is about 50,000,000 miles. If this be so, \$ Lyre is a binary of the \$ Aurige type, but differing from it in the fact that the component stars have unlike spectra The phenomena could also be pro-duced by a meteor stream, or by an object like the sun, rotating in 12d 22h., and having a large protuberance on it extending over more than 180° of longitude The study of the additional photographs which are being taken will doubtless elucidate the matter

THE POLARIZATION THEORY OF THE SOLAR CORONA .- In THE POLARIZATION THEORY OF THE SOLAR CORONA TIN | Paper read at the Royal Society by Sir William Thomson, D.C.L., the Publications of the Astronomical Society of the Paetfic, PRN, on June 11, 1891.

vol in No 16, 1891, Prof Frank H. Bigelow gives some further results of his investigations of coronal forms, and arrives at some new results. It can be shown that in the case of repulsion of matter in a spherical rotating body like the sun, two poles of repulsion are formed, and the body is polarized about an axis. Within the body the lines of force are parallel about an axis. Within the body the lines of force are parameted the axis of polarization, and their curvature outwide the surface may be calculated. Applying these considerations to the similar coronal forms exhibited in the eclipse photographs of July 1878 and January and December 1889, Prof. Bigglow hinds that the axis of polarization is at the variace of the sun about 43 from the axis of rotation, and taking the radius of the sun as 866,500 miles, the length of the axis to which the lines of force are parallel is 1,729,700 miles Its direction is fixed, and in 1878 parallel 18 1,729,700 miles 13s direction is need, and in 1070 miles 201 2, south pole = 301 6, which referred to the ascending mole of the unit's custor on the plane of the eclipte 1 138 1 349 85, 151 1 311 40, and 12 + 312 55 be taken as the number of revolutions, and the, angular excess during the three intervals between the dates of the above eclipses, the mean duly motion in longitude at the latitude of the coronal pole, 85 '5, 1- found to be 13 13307 From this the following periods of the sun's rotation in latitude 85° 5 is deduced—

Salereal period 27 41171d - 27d 9h 52m 52° Synodic period 29 6358oJ 29d 15h 15m 33%

The formula proposed to express the rotation period in different The formula proposed to express the rotation period in univerent solur lattitudes in $X = 86x^2 - 70^2$ and, where X is the mean daily motion in minutes, and I the lattitude. With this, x ele-ments it is possible to predict the positions of the coronal poles at any epoch, and in consequence the relative form of the coronal at the time, as seen from the earth. A comparison of the calcu-lated results and photographs, obtained during some recent echipses, the coronal properties of the properties of the properties of the coronal policy as universe of the coronal policy of the corona displays a striking concordance. The investigation "also serves to strengthen the conviction that the sun-spots are probably formed by the descent of material from the extremities of the coronal streamers, in a vertical direction upon the sun

OBSERVATIONS OF THE MOTION OF STRIUS - It the Berlin Academy of Sciences on June 4, Prof Vogel communicated some observations of the motion of Sinus in the line of sight Using the iron spectrum as the term of comparison with the spectrum of the star, it was found that the velocity of approach on March 22 was 196 geographical miles per second with respect to the sun With Indrogen comparison lines the velocity found was 1 73 miles per second

RUTERN OF FACKE'S COMPT - A telegram from the Lick Observatory to Prof Kruger, sanounces that Incke's [crodic comet has been observed on its return by Mr Barnard on August 1 9958 G M T, in the position R A, 3h 55m 20 6s, Decl 29° 597 1 N

ON SOME TEST CASES FOR THE MAXWELL-BOLTZMANN DOCTRINE REGIRDING DIS-TRIBUTION OF LINERGY

(1) MAXWELL, in his article (///ii/ Mor., 1860) "On the Collision of Elastic Spheres," counciles a very lemarkable theorem, of primary importance in the kinetic theory of gases, to the effect that, in an assemblage of large numbers of mutually-colliding spheres of two or of several different magni-tudes, the mean kinetic energy is the same for equal numbers of the spheres irrespectively of their masses and chameters, or, in other words, the time averages of the squares of the velocities of individual spheres are inversely as their masses the mathematical investigation given as a proof of this theorem in that first article on the subject is quite unsatisfactory , but the mere enunciation of it, even if without proof, was a very valuable contribution to accence In a subsequent paper ("I)ynamical Theory of Gaes," Plh. Trans. for May 1866) Maxwell hinds in his cutation (34) ("Collected Works," p 47), as a result of a thorough mathematical investigation, the same theorem extended to include collisions between Boscovich points with mutate forces. according to any law of distance, provided only that not more than two points are in collision (that is to say, within the dis-tances of their mutual influence) amultaneously. Tait confirms Maxwell's original theorem for colliding spheres of different

magnitudes in an interesting and important examination of the subject in §§ 19, 20, 21 of his paper "On the Foundations of the Kinetic Theory of Gases" (Trans. R.S. E. for May 1866)

(2) Boltzmann, in his "Studien über das Gleichgewicht der lebendigen Kraft zwischen bewegten materiellen Punkten" (Sitzb K Akad Wien, October 8, 1868), enunciated a large extension of this theorem, and Maxwell a still wider generaliza-Distribution of Energy in a System of Material Points "(Cam-Mixwell's "Scientific Paners," pp. 713-41), to the following effect (p 716) --

"In the ultimate state of the system, the average kinetic energy of two given portions of the system must be in the raiso of the number of degrees of freedom of those portions

Much disbelief and doubt has been felt as to the complete truth, or the extent of cases for which there is truth, of this proposition

(3) For a test case, differing as little as possible from Max-well's original case of solid elastic spheres, consider a hollow spherical shell and a solid sphere—globule we shall call it for brevity—within the shell I must first digress to remark that what has hitherto by Maxwell and Clausius and others before and after them been called for brevity an "elastic sphere." is not an elastic solid, capable of rotation and of clastic deformanot an elastic solid, capable of rotation and of classic deforma-tion; and therefore capable of an infinite number of modes of steady vibration, into which, of finer and finer degrees of notal subdivision and shorer and shorter penods, all translational energy would, if the Boltmann-Maxwill generalized proposition were true, be ultimately transformed by collisions. The "smooth elastic spheres" are really Boscowich point arous, with their translational ineria, and with, for law of force, zero force at every distance between two points exceeding the sum of the radii of the two halls, and infinite repulsion at exactly this We may use Boscovich similarly for the hollow shell with globule in its interior, and so do away with all question as to vibrations due to elasticity of material, whether of the shell or of the globule. Let us samply suppose the mutual action between the shell and the globule to be nothing except at an instant of collision, and then to be such that their relative com-ponent velocity along the radius through the point of contact is reversed by the collision, while the motion of their centre of mertia remains unchanged

nortia remanu suchanged (4) For heroly, we hall call the shell and interior globule of \$2,5 a footble molecule, or sometimes, for more heroly, a stamply an stom, or a single along his different construction or surface of the category and the radius or diameter or surface of the category and the radius or diameter or surface of the category and the radius or diameter or surface of the corresponding sphere (Tau explanation is necessary to avoid an ambiguity which might occur with reference to the common expression "sphere of action" of a

Boscovich atom) (5) Consider now a vast number of atoms and doublets, inclosed in a perfectly rigid fixed surface, having the property of reversing the normal component velocity of approach of any atom or shell or doublet at the instant of contact of surfaces, while leaving unchanged the absolute velocity of the centre of inertia of the two Let any velocity or velocities in any direction or directions be given to any one or more of the atoms or of the shells or globules constituting the doublets. According to the Boltzmann-Maxwell doctrine, the motion will become distributed through the system, so that ultimately the time-average kinetic energy of each atom, each shell, and each globule shall be equal; and therefore that of each doublet double that of each atom. This is certainly a very marvellous conclusion; but I see no reason to doubt it on that account After all, it is not obviously more marvellous than the seemingly well-proved conclusion that in a mixed assemblage of colliding single atoms, some of which have a million million times the surge storm, some of which have a militon million times to mass of others, the smaller masses will ultrastely average a million times the velocity of the larger. But it is not included in Maxwell's proof of single atoms of different masses [43] of his "1 lynamical Theory of Gaees" referred to above]; and the condition that the globules incloved in the shells are prevented by the shells from collisions with one another violates Tait's condition [(C) of § 18 of "Foundations of K T Gases"], "that there is perfectly free access for collision between each pair of particles whether of the same or of different systems." An independent investigation of such a simple and definite case as that of the atoms and doublets defined in 88 3-5 is desirable as a

test, or would be interesting as an illustration were test not needed, for the exceedingly wide generalization set forth in the Boltzmann-Maxwell doctrine,

(6) Next, instead of only a single globule within the shell of \$4. let there be a vast number. To fix ideas let the mass of the shell be equal to a hundred times the sum of the masses of the million million Let two such shells be connected by a pushmillion million. Let two such shells be connected by a pash-and-pull massless spring. Let all be given at reat, with the spring stretched to any extent, and then left free. According to the Boltzmann-Maxwell doctrine, the notion produced initially by the spring will become distributed through the system, so that ultimately the sum of the kinetic erregies of the globules within each shell will be a bundred million million times the average kinetic chergy of the shall. The average times the average kinetic energy of the shell in a average velocity of the shell will ultimately be a hundred-millionth of the average velocity of the globules. A corresponding proposition in the kinetic theory of gases is that, if two rigid shells, each weighing I gram, and containing a centigram of monatomic gas, be attached to the two prongs of a massless perfectly elastic tuning fork, and set to vibrate, the gas will become heated in virtue of its viscous resistance to the vibration excited in it by the vibration of the shell, until nearly all the initial energy of the tuning-fork is thus spent.

(7) Going back to the double molecules of § 5, suppose the internal globule to be so connected by massless springs with the shell that the globule is urged towards the centre of the shell with a force simply proportional to the distance between the centres of the two This arrangement, which I gave in my molecules embedded in ether, would be equivalent to two masses connected by a massless spring, if we had only motions in one line to consider, but it has the advantage of being perfectly isotropic, and giving for all motions parallel to any fixed line exactly the same result as if there were no motion perpendicular to it. When a pair of masses connected by a spring strikes a fixed obstacle or a movable body, with the line of their centres not exactly perpendicular to the tangent plane of contact, it is caused to rotate. No such complication affects our isotropic doublet. An assemblage of such doublets being given moving about within a rigid inclosing surface, will the ultimate statistics be, for each doublet, equal average kinetic energles of motion of centre of inertia, and of relative motion of the two eonstituents?

(8) If we try to answer this question synthetically, we find a complex and troublesome problem in the details of all but the very simplest case of collision which can occur, which is direct very simplest case of collision which can occur, which is direct collision between two not previously whenting doublets, or any collision of one not previously whenting doublet against a fixed plane. In this case, if the masses of globule and shell are qual, a complete collision consists of two impacts at an interval of time equal to half the period of free vibration of the doublet, and after the second impact there is separation without vibration, just as if we had had single spheres invent of the doublets

1 he "wenge relocity of a particle," prespectively of direction, i.e. the homes theories the sign of a particle, "prespectively of direction, i.e. the homes the wind of the square root of the time swrage of the square of its velocity containment, and, conversely, equal average homes energies of the two continuents, except in conversely, equal average homes energies of the two continuents, except in a conversely, equal average homes energies of the low continuents, except in a conversely, equal average homes energies of the low continuents, except in a converse of two masses, "m, m, personal continuents of two masses," m, m, personal continuents of two masses, "m, m, personal continuents of two masses, "m, m, personal continuents of two masses of tw

$$\kappa = U - \frac{m'r}{m + m'}, \qquad \kappa' = U + \frac{mr}{m + m}. \tag{1}$$
 whence

$$mu^2 \cdot m'u'^2 = (m - m)\left[U^2 - \frac{mm'r^2}{(m + m)^2}\right] - \frac{4mm'}{m + m'}Ur$$
 (2)

Now suppose the time-average of Ur to be zero. In every ca e in which this is so, we have, by (2), t me-av $(mn^2 - m'n z) = (m - m') \times \text{Time av} \left\{ U^2 - \frac{mm'r^2}{(m + nc)^2} \right\}$ (3)

Hence in any case in which
$$(m+m)^2$$
 Time-av $m'n^2$. (4)

$$1_{1000-8V} mu^2 = T_{100-8V} m'u^2$$
 . (4)

$$(m-m) \times \text{Time-av} \left\{ U^2 - \frac{mm'r^2}{(m+m)^2} \right\} = 0, . . (5)$$

and therefore, except when
$$m = m'$$
, we must have

Tume-av $(m + m)U^2 = T_1me-av \frac{mm'r^2}{M + m'}$. . (6)

which proves the proposition, because, as we readily see from (1), $\frac{1}{2}mm'^2l(m+m')$ is, in every case, the kinetic energy of the relative, motions, m-U, and U-m'.

But in oblique collision between two not previously vibrating But in oblique collision between two not previously viorating doublets, even if the masses of shell and globule are equal, we have a somewhat troublesome problem to find the interval between the two impacts, token there are sixe, and to find the final resulting vibration. When the component relative motion parallel to the tangent plane of the first impact exceeds a certain parasite to the tangent pains of the first impact exceeds a certain value depending on the radius of the outer surface of the shell, the period of free wibration of the doublets, and the relative velocity of approach, there is no second impact, and the doublets separate with no relative velocity perpendicular to the tangent plane, but each with the energy of that component When of its previous motion converted into vibrational energy the mass of the shell is much smaller than the mass of the interior globule, almost every collision will consist of a large number of impacts It seems exceedingly difficult to find how to calculate true statistics of these chattering collisions, and arrive at sound conclusions as to the ultimate distribution of energy in any of the very simplest cases other than Maxwell's original case of 1860, but, if the Boltzmann-Maxwell generalized doctrine is true, we ought to be able to see its truth as essential, trine is true, we ought to be anot to see its truth at essential, with special clearness in the simplest cases, even without going through the full problem presented by the details. I can find nothing in Maxwell's latest article on the subject (Camb Phil Trans., May 6, 1878), or in any of his previous papers, proving an affirmative answer to the question of 8.

(9) Going back to § 6, let the globules be initially distributed as nearly as may be homogeneously through the bollow, let each globule be connected with neighbours by massless springs, and let all the globules which are near the inner surface of the shell be connected with it also by inassless springs. Or let any number of smaller shells be inclosed within our outer shell, and connected by massless springs, as represented by the accompanying diagram, taken from a reprint of my Bal-timore Lectures now in progress. Let two such outer shells,

given at rest with their systems of globules in equilibrium within them, be connected by massless springs, and be started in motion, as were the shells of § 6 There will not now be the great loss of energy from the vibration of the shells which there great loss of energy from the contrary, the ultimate average kinetic energy of the whole two hundred million million globules will be energy of the wnote two nuncired million million grounts wat se-certainly small in comparison with the ultimate average kinetic energy of the single shell. It may be because each globule of § 6 is free to wander that the energy is lost from the shell in that case, and distributed among them. There is nothing vague in their motion allowing them to take more and more energy, now when they are connected by the massless springs. If we suppose the motions infinitesimal, or if, whatever their ranges suppose the interest are in simple proportion to displacements, the elementary dynamical theorem of fundamental modes shows how to find determinately each of the 600 million million and six simple harmonic vibrations, of which the motion resulting from the prescribed initial circumstances is constituted. It tells us that the sum of the potential and kinetic energies of each mode remains always of constant value, and that the time-average of the changing kinetic energy during its period is half of this constant value. Without fully solving the problem for the 600 million million and six co-ordinates, it is easy to see that the gravest fundamental mode of the motion actually produced in the prescribed circumstances differs but little in period and energy from the single simple harmonic vibration which the two shells would take if the globules were rigidly connected to them, or were removed from within them, and the other initial circumstances were those of § 6. But this conclusion depends on the forces being rigorously in simple proportion to displacements

(10)1 In no real case could they be so, and if there is any deviation from the simple proportionality of force to displace-Sections to to 17 added July to, 1891

meni, the independent superposition of motions does not hold good. We have still a theorem of fundamental modes, although, so far as I know, this theory has not yet been investigated. For so far as I know, this theory case not yet been investigated. For any stable system moving with a given sum, E, of potential and kinetic energies, there must in general be at least as many fundamental modes of rigorously periodic motion as there are freedoms (or independent variables). But the configuration of freadons (or independent variables) But the configuration of each fundamental mode is now not generally similar for different values of E, and superposition of different fundamental modes now the same or with different values of E, Ass now no meaning. It seems to me probable that every fundamental modes re-sentially unstable. It is not if Mas, well's fundamental mode re-sentially unstable. assumption 1 " that the system, if left to itself in its actual state assumption." That the system, it left to itself in its actual state of motion, will, sooner of itself, pass through every phase which is consistent with the equation of energy." is true. It seems to me quite probable that this assumption it true, provided the "actual state of motion." Is not exactly, as it position and evolucity, a configuration of some one of the fundamental modes of rigorously periodic motion, and provided also that the "system" has not any exceptional character, such as those indicated by Maxwell for cases in which he warns ' us that his assumption does not hold good

assumption does not note good

(11) But, conceding Maxwell's fundamental assumption, I do
not see, in the mathematical workings of his papers any proof of his conclusion "that the average kinetic energy correspond-ing to any one of the variables is the same for every one of the variables of the system" Indeed, as a general proposition its meaning is not explained, and seems to the inexplicable reduction of the kinetic energy to a sum of squares I leaves the several parts of the whole with no correspondence to any defined or definable set of independent variables What, for example, can the meaning of the conclusion 5 be for the case of a jointed pendulum? (a system of two rigid bodies, one supported on a fixed horizontal axis and the other on a parallel axis fixed relatively to the first body, and both acted on only by gravity) The conclusion is quite intelligible, however that is it true?), when the kinetic energy is expressible as a sum of squares of rates of change of single co ordinates each multiplied by a function of all, or of some, of the co ordinates 5 Con-older, for example, the still easier case of these coefficients

(12) Consider more particularly the easiest case of all, motion of a single particle in a plane, that is, the case of all, motion of a single particle in a plane, that is, the case of just two independent variables, say x, y, and kinetic energy equal to $\frac{1}{2}(1+y^2)$. The equations of motion are

$$\frac{d^2x}{dt^2} = -\frac{dV}{dx}, \qquad \frac{d^2y}{dt^2} = -\frac{dV}{cy},$$

where V is the potential energy, which may be any function of x, t, subject only to the condition (required for stability) that it is essentially positive (its least value being, for brevity, taken as zero). It is easily proved that, with any given value, E, for the sum of kinetic and potential energies, there are two determinate modes of periodic motion, that is to say, there are two finite closed curves such that, if m be projected from any point of other with velocity equal to $\sqrt{[2(k-V)]}$ in the direction, either wards, of the tangent to the curve, its path will be exactly that curve In a very special class of cases there are only two such periodic motions, but it is obvious that there are more than two in other cases. (t3) Take, for example.

$$V = \frac{1}{4}(a^2x^2 + \beta^2y^2 + cx^2y^2)$$
For all values of E we have
$$x = a \cos(ax - c)$$

$$y = 0$$

$$y = 0$$
and
$$y = 0$$

$$y = 0 \cos(\beta t - f)$$

as two fundamental modes. When E is infinitely small we have only these two, but for any finite value of E we have clearly an infinite number of fundamental modes, and every mode differs infinitely little from being a fundamental mode To see this let m be projected from any point N in OX, in a direction per-pendicular to OX, with a velocity equal to $\sqrt{(2E - \alpha^2 ON^2)}$.

Crannife Papers,vol. in p 744 ** \$^{1} Ibid., pp 714, 715 **
\$^{1} Ibid., pp, 716-776 **
\$^{1} Ibid., pp, 716-

After a sufficiently great number of crossings and res-crossings across the line XOX, the particle will cross this line very userly at the state at a term point. We are the state of the s

formulated in § 13; and an interesting problem is presented, to find (by the method of the "variation of parameters") a, c, b, f. slowly varying functions of t, such that

$$x = a \sin(at - c),$$
 $y = b \sin(\beta t - f),$
 $x = aa \cos(at - c),$ $y = b\beta \cos(\beta t - f),$

shall be the rigorous solution, or a practical approximation to Careful consideration of possibilities in respect to this case [cE/(a²B²) very small) seems thoroughly to confirm Maxwell's fundamental assumption quoted in § 11, and that it is correct whether cE/(a282) be small or large seems exceedingly probable, or quite certain.

(14) But it seems also probable that Maxwell's conclusion, which for the case of a material point moving in a plane is

Time av
$$t' = Time av y^2$$
, (

es not true when a' differs from B' It is certainly not proved No dynamical principle except the equation of energy,

$$(f' + v') = E - V$$
.

is brought into the mathematical work of pp 722-25, which gives by Maxwell as from 1. Hence on path and by desen gives by Maxwell as the season of for the path without nating the dynamics which enters into Maxwell's investigation, and we may draw curves for the path such as to satisfy (1), and curves not satisfying (1), but all travening the whole space within the path of the path with the path of the path with the path of the path with the path of the path bounding curve

$$\frac{1}{2}(\alpha^{n}1^{3} + \beta^{n}y^{n} + c1^{n}y^{n}) = 1,$$

and all satisfying Maxwell's fundamental assumption (\$ 11) (16) The meaning of the question is illustrated by reducing it to a purely geometrical question regarding the path, thus --Calling 8 the inclination to r of the tangent to the path at any point is, and o the velocity in the path, we have

$$x = q \cos \theta$$
, $y = q \sin \theta$, . (4)
and therefore, by (2),
 $q = \sqrt{|z(E - V)|}$, (5)

 $q = \sqrt{|\mathbf{z}(\mathbf{E} - \mathbf{V})|}$. Hence, if we call s the total length of curve travelled,

$$\int v'dt = \int q \cos^2\theta \, q dt = \int \sqrt{(2(F - V))^2 \cos^2\theta} \, ds \, ,$$

and the question of § 15 becomes, Is or is not 1 / de /(2(E - V)) cos' θ

$$= \frac{1}{5} \int_{0}^{\infty} ds \sqrt{\left(a(E - V)\right)} \sin^{2}\theta^{2} . \quad (7)$$

where S denotes so great a length of path that it has passed a where Successed agreat a length of pain that it has passed a great number of times very near to every point within the boundary (3), very nearly in every direction (17) Consider now separately the parts of the two members of (7) derived from portions of the path which cross an infinitesimal

area do having its centre at (1, y). They are respectively

and
$$\frac{\sqrt{(2(E-V))} d\sigma \int_{0}^{T} N d\theta \cos^{2}\theta}{\sqrt{(2(E-V))} d\sigma \int_{0}^{T} N d\theta \sin^{2}\theta} , ... (8)$$

where Nat denotes the number of portions of the path, per unit where two denotes the minimed $\frac{1}{2}x + \theta$ to t, which pass eitherwards across the area in directions inclined to a at angles between

the values $\theta = \frac{1}{2}d\theta$ and $\theta + \frac{1}{2}d\theta$. The most general possible expression for N is, according to Fourier,

$$N = A_0 + A_1 \cos 2\theta + A_2 \cos 4\theta + &c. + B_1 \sin 2\theta + B_4 \sin 4\theta + &c.$$
Hence the two members of (8) become respectively.

and
$$\sqrt{(2(E-V))d\sigma_2^2\pi(\Lambda_0+\frac{1}{2}\Lambda_1)}$$
 (10)

$$\sqrt{(2(E-V))/d\sigma_2^2\pi(A_a-\frac{1}{2}A_1)}$$
 surking that A_a and A_1 are functions of x , y , and taking

Remarking that A_s and A_1 are functions of x, y, and taking dx = dxdy, we find, from (10), for the two totals of (7) respectively

$$= \frac{1}{2}\pi \iint d^{4}dy (\Lambda_{0} + \frac{1}{2}\Lambda_{1}) \sqrt{[2(E - V)]} \Big|_{Y},$$

$$= \frac{1}{2}\pi \iint d^{4}dy (\Lambda_{0} - \frac{1}{2}\Lambda_{1}) \sqrt{[2(E - V)]} \Big|_{Y},$$
(11)

where $\int \int d^4x dy$ denotes integration over the whole space inclosed by (3) These quantities are equal if and only if | | dudyA1 vanishes, it does so, clearly, if a = B; but it seems improbable that, except when $\alpha = \beta$, it can vanish generally, and unless it does α , our present lest case would disprove the Boltzmann Maxwell general doctrine

Tfills Congress began its proceedings on Monday. Fourteen countries and forty-six (eographical Societies are officially represented. France has sent 73 delegate, (eremany 33, Austria Hungary 21, Switzerland 87, Italy 21, Russin 13, Grat Bintain 8, and spun, America, and the Netherlands two each Egypt, Portugal, Roumania, Greece, Norway, and Sweden are also represented There are, in addition, 150 Members and Associates who have not yet given in their names

M. Numa Dior. Swiss Minister for Foreign Affairs, bade the

delegates heartily welcome to Berne

Dr Gobat, Regicinagorath, Berne, President of the Congress, then delivered his managural address. In the name of the Geographical Societies of Switzerland he thanked the savan's

Cographical Societies of Swirerland he thanked the network present for responding to containly to their univitation.

Among the good work already done, Prof. Penck, of Yunna, his proposed the following revolution. —"This Congress on the geographical sciences, held at Berne, resolves to take the initiative in the presentation of a large map of the earth out a scale of one to a million, of which the various sections shall be delimited by lautades and longitudes, and, with this object, it appoints an international committee to determine the principles upon which the preparation of such map shall proceed. The members of this committee shall arrange that the various States engaged in preparing maps, the societies and periodicals pub-lishing original maps, and all private geographical establishments working in this field shall prepare detached sections of the said map, the sale of which shall also be regulated and arranged for (6)

by the committee. In the course of his address on the subject Prof. Penck oald a high tribute to the services rendered by Mr Stanley to the cause of geographical science, directing special attention to the fact that each of the explorer's expeditions across Africa had led to the preparation of from 20 to 30 maps

The proposal was referred to a committee of the Congress, which will report upon it

The subjects of an initial meridian and universal time, geo replaced eduction, orthography of geographical deduction, orthography of geographical names, lakes and glaciers, cartography, bibliography, meteorology, commercial geography, and voyages and travels are all to be touched upon in the deliberations

SCIENTIFIC SERIALS.

Journal of the Russian Chemical and Physical Society, vol. xxiii, No 1.—The chief papers are —On the molecular weight of albumen, by A. Sabanceff and N. Alexandroff. Several determinations were made on the method of Raoult, and gave an average of 14,276, the molecular weight thus appearing to be nearly three times as great as that deduced from the formula of Harnack (4730), and nearly nine times as high as that given in Lleberkuhn's formula (1612). The molecule contains nine atoms of sulphur, of which two are easily separated Sub-mitted to a temperature of 40°, the solution of albumen changes its properties, and its temperature of freezing is lowered —On the measurement of density of sea water, by Vice Admiral measurement of density of sea water, Makaroff. This elaborate work gives the results of measure-ments made on board the corvette Vitya: The value of various instruments used during the crulse is discussed in de-tail, and the following formulæ are given as expressing the results of the observations between the temperatures of o and For distilled water, the density is-

 $S_c = 0.9998795$ = $S_c(1 - 0.000061398t + 0.0000080021t^2 - 0.0000004586t^3),$

maximum density at 3° 972 For sea water, the density of which at 15° compared with that of distilled water at 4° is = 1 019, the formula is—

S, = 1'0207769

 $=5.(1+0.000022268t+0.0000069801t^3-0.00000004761t^8).$ maximum density at - 1° 570. For sea water, the density of which, also at 15°, is - 1 026, the formula is-

S.= t 0280936

 $= S_{1}(1 + 0.0000504537 + 0.00000628337^{2} - 0.000000038527^{3}),$ maximum density at -3'876. The last two formulæ gave excellent results for temperatures down to -5'. A comparison between the figures obtained by the I'll as and those obtained by the Challenger proved very satisfactory Finally, the author gives six most valuable tables of corrections Tables L and II. contain the corrections to be applied to S 15 for obtaining

 $S_{\overline{A}}^{\prime}$, and va_{ij} $v_{ij}v_{ij}d$, from -5 to +36°, for both distilled and sea-water Detailed interpolation tables are also given Table III contains the corrections due to the coefficient of dilatation of glass of the arcometer being not equal to the normal coefficient o 000028. The three other tables are for transferring densities S17 5 into densities S15 17.5

Bulletin de la Socilié des Naturalistes de Moscou, 1890, No 3-On the Protopirata centrodon, Ted, by H Trautschold (in German) The two Ichthyodornlithes from the Carboniferous of North America, described in J. S. Newberry's capital work upon the "Palæozoic Fishes of North America," Table xxxix, are very much like the Moscow fossils described by the author in are very much like the above ow to said elevative by the author in the above periodical (1884 and 1856) unler the names of Eddtus polopyrada, and later on, of Prodyrada centrodon—Geo-boanical notes about the flore of European Russas, by D. I. Litunoff (in Russian). The common Soutch fit (*Irius ylvistitu) grows, as known, chiefly on a sandy soil. However, it also appears in the hilly tracts of Europe and Asia, and there it grows upon a rocky soil, chiefly limestone. In the lowlands of Germany and Russia, the appearance of fir upon a rocky the Granday and Russa, the appearance of fir upon a responsible for the first product of the first product which are not met with elsewhere in the Russian plains, and with a number of endemic plants very rare in Russia as a whole. with a number of endemic piants very rare in Russia as a wnote. The author considers these rocky islands of fir-growths as surrivals from the pre Glacial period. The paper is full of most interesting botanical data and valuable remarks upon the con-nection of the glacistion of Russia with its present flora —The influence of friction upon the rotatory motion of celestal bodes, by Th Sloudsky (in French) The auxiliary theorems, upon which the principal theorem relative to the effects of friction is based, are demonstrated, the sun being taken as an illustration based, are demonstrated, the sun being taken as an illustration—On the outpin of enclopers in the embryo-position of certain Gymosoperms, by Miss C. THURSDAY, AUGUST 20, 1891,

THE CONGRESS OF HYGIENE

THE proceedings of this Congress were brought to a close on Monday, it being generally conceded that the importance of the conclusions arrived at and of the discussions on the more important topics were on a level with the numbers and eminence of the men of science taking part in the deliberations.

So far as space permits, we shall endeavour to give an account of some of the most salient subjects touched in the different Sections To get a general idea of the enormous area of the ground covered, it is only necessary to glance at the resolutions adopted It will be generally conceded that the members of the Congress are by these resolutions supplied with much food for thought in the interim which will elapse till the next meeting, which has been fixed at Budapest and for 1894

We note with the greatest pleasure that Her Majesty and the University of Cambridge have shown their appreciation of the honour done to the nation by the presence of so many foreigners, and that other bodies and individuals have not been lacking to render possible gatherings of a less severely scientific character than

the Sectional meetings

Her Majesty's action in inviting many of the most eminent representatives of different nationalities to Osborne-an action, we believe, suggested by the Prince of Wales-has been so well received, that one regrets that the nation has had to wait so long for such a precedent We regret it, not so much for the sake of men of science. but because the result has been that Royalty here has always lived apart not only from science but from national culture generally. The Queen, indeed, on the present system, never need know anything, except by some happy accident, of Britain's greatest men.

The party which went to Osborne left early by a special train, and were taken over from Portsmouth in the Queen's yacht. They were accompanied by Sir D Galton, Dr Poore, Prof. Corfield, and Mr S Digby Luncheon was provided at 2, and Her Majesty later on received the visitors, of whom the following is an official list .-

Austra-Hungury.—Dr. Emil Kusý, Ministerialrath, Sanitats referent, delegated by Minister of the Interior, Hofrath Franz Ritter von Cruber, Professor of Architecture, elegated by Imperal Council of Health; Dr. Ernst Hofrath Ludwig. Pro-fessor of Applied Chemistry a Harbological Institute, delegated by Minister of Finance, Dr. J Fodor, Professor of Hygene, University of Budapeut, delegated by Minister of Public Worship and Education.

Belgium.-M E. Beco, Secretary-General of the Department Bidgiam.—M. E. Beco, Secretary-General of the Department of Agricultur, Industry, and Public Works, delegated by Agricultur, Changara, and Commission Central de Statistyne de Bidgiage, del Academie Commission Central de Statistyne de Bidgiage, del Academie Royale de Médeane et du Consell Suprirear d'Hygiene Royale de Médeane et du Consell Suprirear d'Hygiene Smitzy, Council, delegated by the Danish Ocerement; Hara V Berg, Médical Director of the Navy, delegated by Daanh Naval Department, Sart. Od. Lauk, delegated by the Danish delegated by the Danish Consellation of the Medical Director of the Navy, delegated by Daanh Naval

Department.

The final general meeting of the Congress was held on Monday, under the presidency of Sir Douglas Galton

Manam Lupercalia, p. 374 of Bachrens, Frag. post Rem. NO 1138, VOL. 44] There was a large attendance, and among those present were nearly all the foreign delegates.

The Chairman, in opening the proceedings, after some pre-liminary remarks, said ... The success of the Congress, as an interliminary remarks, said —The success of the Congress, as an inter-national gathering, is due to the fact that we as a nation have many matters of interest to show to foreigners. I think I may say that the chief difference between our hygienic progress and that of our Continental neighbours is that, whilst they are especially fortunate in being able to pursue the theories upon which much of modern hygienic progress is based, with us public which much of modern hygienic progress is based, with us public opinion has hindered the study of many physiological questions, the solution of which depends upon the examination of living tissue. Hence, we at pre-ent are in this respect somewhat behind the Continental sehools, and we largely turn our attention to apply their theories to alleviate the wants of life. Hence we can show much do'unterest in practical byguene in matters both of construc-tion and adimmeration. Our methods of water supply and dramage, our various plans for refuse disposal or mithration, our costions hotpstala and ambulance systems present many miter esting features. The mrangements which are being made to introduce saminty knowledge and efficiency of workman-ters of the matter of the state of the state of the state title and the state of the state of the state of the title and the state of the state of the state of the state tall samintion of parts of our houses bygely depends, are deserving of consideration, and the health similiar trations of the large exists of Claegow and Manchester is expectally worthy of the study of our visitors. The organiza-tion of this Congress has differed from that of former Con-gress in the merested number of vections in an effective pro-gress in the merested number of vections in an energy and becomes more elaborate, the classification must necessarily be much of interest in practical hygiene in matters both of construc more detailed, and the number of Sections must either gradually increase or the Sections must subdivide. Independently of the merease or the sections must subdivide. Independently of the increased number of sections, it was found necessary to give two afternoons to the discussion of questions connected with the sanitation of our Indian Fuppire, which, for the first time in the human of the Cornel. history of these Congresses, was repie ented by a large number of delegates. The native Princes of India evinced deep sympathy with the Congress, and I trust that the interest which has been evoked in its object may lead to beneficial results in that great country . A principal object of the Congress is, without doubt, to afford to scientific men in different countries is, without doubt, to afford to scientific men in different countries the opportunity of conferring together. But it has another and most imprising the properties of the properties of the laws of health. Your President the other day saked the pertinent question—Why, if diseases are preventable, are they not pravented? The answer to that question is that, whilst an instructed answer to that question is that, which an information in minority may understand the importance of observing hygienic laws, a very large section of the community is careless of and indifferent to their observance, and consequently the portions of those laws which are individual and personal in their application are left a dead letter. Acts of Parlament are of little avail so long as the people they are framed to guide do not realize their value or importance, and it is quite certain that the only way to stamp out preventable disease is to educate every member of the community to feel the importance of the every member of the community to teet the importance of the laws of health. A great international Congress like his brings the subject prominently before the public and has a valuable influence on the country in which it is held. I have already detained you too long. But I must add, as chairman of the detained you too long. But I must add, as chairman of the organizing committee, that we have endeavoured to make the organizing committee, that we have endeavoluted to make the Congress useful and agreeable to those who have honoured us with their presence. The success which we have had is mainly due to our secretary-general (Dr. Poore), our foreign secretary (Dr Corfield), and, as far as India is concerned, to the energy of Mr Digby. The excellence of the social arrangements is of Mr Deby. The scellence of the social arrangements is entirely due to the organizing power and tast of the secretary of the reception committee, Mr. Malcolm Morris. But you will have an opportunity of thanking the executive before the end of this meeting. If there have been shortcoming, the organizing committee much regire them. The only apology we can offer is that a voluntary organization studiesly creates but strated requirements of the monature measured on Mondes members. requirements of the moment may have been somewhat strained at first by the number who appeared on Monday morning—a number far in excess of that which former experience led us to anticipate, and I would say in conclusion, in the words of our poet Frior—

" Be to our virtues very kind. Be to our faults a little blind "

The meeting next discussed the place of the next Congress; we have already stated that Budapest was fixed upon.

we have a fready stated that Budapest was freed upon.
You'se of thanks complied the business. Among these, Dr.
San That Hat Royal Highness the President be respectfully requested to convey to Her Majesty's gracious act in becoming of the Congress for Her Majesty's gracious act in becoming Patron of the Congress, and for the magnificent hospitality shown by Her Majesty to members of the Congress during their solourn in England

Prof. Kuy (Austrin) seconded the resolution.

Colonel Woodhall (United States) said that all members of Colonel Woodhall (United States) said that all members of the Congress must desire to express their gratitude for the way in which they had been received by that gracious lady Her Majesty the Queen, whose purity and dignity of life had enabled her to extend her empire of love and respect over even American

cuttens

The resolution was unanimously agreed to The resolution was unanimously agreed to His Excellency M Gennadius, the Minister for Greece, moved the following resolution —"That the best thanks of the Congress be dutifully tendered to His Royal Highness, the Prince of Wales, the President of the Congress, for the unitring interest which His Royal Highness has manifested in the Congress, and to which the success of the Congress is to be largely attributed."

attributed."
Finally, the Charman proposed a vote of thanks to the officers of the Association, whose unsparing work and indefaugablementy had so largely conduced to the aucers of the undersking. He coupled with the vote the names of Dr. G V. Poore, the hon-secretary-general, Prof W H Corfield, the hon foreign secretary-general, Prof W H. Corfield, the hon foreign secretary, and Mr Makiolin Morra, the hon secretary of the reception

eommittee
The vote was warmly received, and was unanimously adopted.

The Permanent International Committee have appointed the following International Sub-Committee to prepare a scheme for the organization of future Con-The Sub-Committee consists of Prof Dr Brouardel, Hon Ll. D Cantab (France), Prof Dr. Fodor, Hon LL D Cantab (Hungary), and Prof Corfield (England), to represent Hygiene, and M. Koiosi (Hungary) and Dr. Janssens (Belgium) to represent Demography.

It is understood that the Sub-Committee will consider the advisability of forming Permanent Committees in various country, the plan of having Committees outside the country in which the Congress is held having proved so successful in obtaining Foreign Members for the London Congress, at which it was adopted for the first time

This week we give an account of the work done in the Section of Preventive Medicine.

In this Section the President, Sir Joseph Fayrer, K.CSI, F.R.S., commenced the proceedings by delivering the following inaugural address:-

My first duty on occupying this seat is to make fitting acknowledgment of the honour which has been conferred on me, and to assure those to whom I am indebted for it that, as I apand to assure those to whom I am indebted for it that, as I appreciate the distinction highly, so, with the and of my colleagues in this Section, and the support of the meany eminent men of science who will take part in its work, I hope to discharge faithfully the important trust reposed in me. My next and most agreeable duty is to offer to all who honour us with their presence, or who propose by co-operation to forward the obpresence, or win progress, a most hearty welcome and cordial re-cognition of the interest in it manifested by their presence; to express a hope that the deliberations and conclusions which re-sult from their wisdom and experience may advance our know-ledge, and tend to enhance the welfare of the human race. This ledge, and tend to enhance the weinare of the numan race. This hope is based upon the universal recognition of the need of, and capacity for, improvement in the conditions upon which physical well-being, immunity from disease, and peolongation of life depend; and this is evinced by the assembling together in

this Congress of men of science from all parts of the world, who have devoted themselves to the great international, humanihave devoted themselves to the great international, numbers tarian purpose of ameliorating the conditions of mankind every where, so far at least as the application of the laws of health, and to some extent those of sociology, can affect this consumma tion. To all, then, we in this great city, who are interested in the progress of hygiene and demography, offer our cordial greet-ing, and express an earnest desire that our visitors may derivpleasure and benefit from their sojourn in London, and from the proceedings of the great assembly of which they form so im-

proceedings of use given assuming to portant a part.

Before I muste Dr. Caningham to open the first subject for discussion, it is right that I should make a few preliminary remarks on the general scope and objects of the work comprised in this section. I do not intend to occupy must of this section I do not intend to occupy must be this section. I which the service the processing the processing of the short and valuable time at our disposal by discussing any special subject, or by anticipating that which those who follow me may have to say, but shall confine myself to a brief follow me may have to say, but shall confine myself to a breet notice of the present aspects of preventive medicane, its recent development, how much it has operated and is now operating for the public good, how slowly but surely it is dispelling the cloud of ignorance and prejudice which has overshudowed and impeded the projects of sanitation, and how it is gradually imbuing only the public good of the good of the public good of the good of th the public mind with the conviction that prevention is better and often easier than cure, that health may be preserved, diease avoided, and life prolonged by the study and observance of certain well-known laws, which, correlating the individual with his surroundings, determine his well being when conformed to, deteriorate or prevent it when neglected, and should enforce the maxim, "Vententi occurite morbo." Unprecetorce the maxim, "Venienti occurite morbo." Unprecedented progress in human knowledge characterizes the preent century, and has not been wanting in prevenitive medicine. It is, however, daring the last half of it that advance has been most renarkable, whilst it is in a later part of that period, that it has so established itself in the popular mind as to have passed from the region of dombs and commendation. ave passed from the region of doubt and speculation into that of certainty It is now pretty generally understood that about of certainty It is now pretty generally understood that about one fourth of all the mortality in England is caused by prevent able disease, that the death-rate of large communities may be reduced much below that at which it has been wont to stand, the average duration of life may be made to approximate nearer to the allotted fourscore, and that the conditions of living may be greatly ameliorated. The clief obstacles to improvement have been ignorance and want of belief, a better knowledge of the laws of life and health, a more rational comprehension of the nature and causes of disease, are gradually but surely entailing improvement in the conditions of living and in the value of life, and the diminution and mitigation, if not extinction, of morbid conditions which have in past times proved so murrous or destructive to life In short, as Dante says

> " Se' I mondo laggiu ponesse mente Al fondamento che natura pone, Seguendo lui avria buona la gente " " Paradiso," viii , 142

Such are the subjects contemplated in the work of this Section and as far as time permits the most interesting of them will be discussed Those selected are of great importance in their relations to public health, let us hope that observers who have formed their opinions from experience in other countries and under different circumstances may throw new light on them

In the brief space of time at my disposal it would be im In the bref space of time at my driposal it would be impossible to give a continuous oulline of the progress of preventive medicine during the past, or to trace its growth and development out of ignorance and superstation to its for the progress of the section of the progress of the section of the best is now fairly grasped by popular sentiment, and that, though ignorance, opposition, and vested interests sell contacts the ground, progress is sure, and the light of sections is illuminating the dark places. It is now better appreciate the progress of th cated than it seer has been, that the causes which induce discuss and aborten life are greatly under our own control, and that we have it in our power to restrain and dimminis them, and to the control of the control

will indicate how much remains to be done. Did time permis, I might illustrate the progress of preventive medicine by constraint the state of England with its population of more than 20,000,000 during the Victorian with the England of the progress of England with its population of more than 20,000,000 during the Victorian with the England of the first of the england of the progress of the england of the progress of the england of the eng

364

If we turn to the preent, we find that great improvements have gradually been made an the mode of living, the houses are better constructed, the drainage and ventilation are more combeted or the present of the presen

If we moure into the effects of certain well-known diseases, we find that they are less severe in their incidence, if not less frequent in their recurrence. With regard to small-pox, annee the passing of the first Vaccinition Act in 1840, the death-though for the five years 1870–74 it was 47, thus showing that though for the five years 1870–74 it was 47, thus showing that there was still much to be learnt about vaccination. Entering fewer was not separated from typhus fewer before 1860, but since the state of the state

spheriae. The a fairly attributable to local staturery rather balant to occurs measures. Preventible disasts etill tally steely about 125,000, and, considering the large number of cases for every death, it has been calculated that 178 millions of days of labour are lost annually, which means £7,75,000 per annuary is also a rate lost annually, which means £7,75,000 per annuary andured by the still too numerous annually has been for the company of the lower town and the still consumerous annually and the expectancy of the lower plagues of the middle ages, yet in this century, now closing, other epidemics have made their papeasance incloser has four times visited us; fevers, empire diseases, and diphthera recently, and after leaving us last year, only to return with renewed virulence, caused in the United States a scortality and anisonst equal to that of the plague. Much has been dose, but much remains to be effected. Let us hope that the future may be more profile of unprovenent that the past; international philanthropy seems to say it shall be so. That disture may be more profile of unprovenent that the past; international philanthropy seems to say it shall be so. That compositions, and though we may never be able to reach the "four expected, but thece cannot be a doubt that we may diminish is uncidence, and though we may never be able to reach the "four towns which give neet to synotic dates, not even of induce which compromise otherwise the phyrical welfare of manking, but should not obviously make the past profile of receivance, involve over competition in various occupant of oversity of the province, professional, or mercanities, by which compromise otherwise the phyrical welfare of manking, but should be surgile for existence Or I might point to the crudescage of those psychical phenoment maintended to the influence of one mud upon another; this is a subject to the discussion of the three watchild notice of the dangerous centeredistics.

which may ensue from it Again, the abuse of alcohol, opium, chloral, and other stimulants and narcotics, and the evil consequences which may result therefrom, is also a subject worthy of consideration and will, no doubt, receive it in a communication which is to be brought before this Section

The poundle deleterous influence of untuken notions of education, as remoded in the over-pressure which is escrived upon the poung the predominance of estimations, their in-the titles that they are the best test of knowledge, whilst true mental culture is in danger of being neglected, and physical training, if no injuried, that the manual culture is in danger of being neglected, and physical training, the proposed, that the manual the scale of the physical properties are the present the properties of the physical preventive medicane, whose duty it is to safeguard the human fee from all avoidable causes of either physical or mental reservoir.

Though preventive medicine in some form has been practised uncer the days of Moss, yet it has received but intle recognition until a companitively recent period; when science developed and observation extended, medical men conditions in producing disease, and thus it was forced upon the public conscience that something must be done; and when philanthropust like John Howard devoted like and when philanthropust like John Howard devoted like existed—q in our galok, where the prisoners not only died of patrid fever, the result of ochleuc causes, but actually infected highest before whom they came recking with the contagon of the prisoner—not contagon of the prisoner—not contagon of the prisoner—not contagon of the prisoner—not sensitively measures gradually sense into opens and the contagon of the prisoner—not sensitively measures gradually sense into question of the prisoner—not sensitively that any selective progress was made; it was when Chadwick, Parkes, and others instituted the work by which they have exame the lasting gratuited of the

haman race that preventive medicine became a distinct branch of medical science. The sanistry condition of towns and communities is not dependent on the views or exertions of indimensions in the control of the contro

"Under the improved system of sanitary administration which now obtains, and is gradually developing to a greater state of perfection, the sanitary administration of very district in the country is intracted to the cure of duly qualified leath officers—country is intracted to the cure of duly qualified leath officers—and from which better still may be anticipated. The records of the pass fifty years prove the influence extented by sanitary measures on vital statetic. The first reliable tables from which the pass fifty years prove the influence extented by sanitary measures on vital statetic. The first reliable tables from which the vast for males 3 gog years, for females 11 to 1850 it had increased to 41 35 for males and 44 66 females. It is, whom also that the expectation of life increases every year up to the fourth year, and decreases after that tables, that dare that age it is less. The improved sanitation swers more than they were at the time of the first table, which accounts for the expectancy of life for stall men being less. Women remain more at home, where the better sanitation talls, and are not expectancy of life for sall men being less. Women remain more at home, where the better sanitation talls, and are not expectancy of life for sall men being less. Women remain more at home, where the better sanitation talls, and are not expectancy of life for sall men being less. Women remain more at home, where the better sanitation talls, and are not decreased death size. Let us compare the death rates of a decreased death size. Let us compare the death rates of England during past times with the present, whether they be a life entire the point in question of these.

	DEATH	-RATE	
1660-79 1681-90 1746-55 1846-55 1866-70	80 per 1000 42 I ,, 35 5 ,, 24 9 ,, 22 4 ,,	1870-75 1875-80 1880-85 1885-88	20 9 per 100 20 0 ,, 19 3 ,, 18 7 ,, 17 85 ,,

In some parts of England, where the man object is the recovery or manitemance of beath, the death-rate is down to 9 per 1000, while in others, where the man object is manufacture and money-making it is as high as 20 per 1000. Nowhere, I think, in the control of the control of the control of the control than in India during the past thirty years. A Royal Commission was appointed after the Crimens was to inquie into the sanitary condition of the British Army, and this in 163 ps was extended to have the control of the control of the control of the insist troops were referred to incidentally. Here the inquiry had to deal with a large body of men, concerning whom, wheir cosditions of custices bury well know, reliable information was

accessible. It was ascertained that up to that time the annual death rate over a long period had stood at 69 per 1000. The inquiry resulted in certain changes and improvements in the housing, clothing, food, and occupation of the soldier. Since those have been carried out there has been a steady decline in the death-rate, and the annual reports of the Santtary Commissioners to the Government of India give the rates as in 1386, 15 189 per 1000; 1887, 14 20 per 1000, 1888, 14 54 per 1000

During some years it have been even lower, down to per 1000, whilst the general efficiency of the troops has increased It is not easy to estimate the money conjugatent of this. but if we take the rough standard which values each soldier a £100, a simple calculation will show how great is the gain, and who can estimate the value of lives saved and suffering avoided? As to native soldiers with whom the European troops may be compared, I find that the death rate was in 1886, 13'27 per 1000 . 1887, 11'68 per 1000 . 1888, 12 84 per 1000 cholera, and other epidemic visuations in some years disturb the regularity of the death-rate, under less favourable conditions of regularity of the death-rate, under less favourable conditions of living, as in the case of prisoners in the gools, it is somewhat higher. In the Indian gools, for example, it was in 1886, 31 85 per 1000, 1887, 34 15 per 1000, 1888, 35 57 per 1000. On the whole, all this indicates improvement, and as regards the civil population progress also is being made, but here, from the civil population progress also is being made, but here, from so many disturbing causes, the figures are neither >0 easily obtained nor so reliable. The compartively large mortality is due to neglect of the common sanitary laws added to extremes of climate, which favour the incidence and diffusion of epidemic. disease, and intensify it when it has once appeared. A Sanuary Department has existed in India since 1866, and every effort is made by Government, at no small cost, to give effect to sanitary laws, there can be little down that the results, so far, are good, that disease generally is diminishing, and that life is of longer duration. An important result of the observations of the able medical officers of the Sanitary Service of India has been to show that cholera is to be prevented or diminished by sanitary proceedings alone, and that all correive measures of quarantine or forcible solution are futile and hurtful. Here I may ay that, large as may appear the death rate from cholera in India (i e in 1888, 1 99 per 1000 for the European army and 1 35 for the civil population), it is small compared with that of fevers, which caused in 1889 4 48 per 1000 in the European army and 17 09 in the civil population, but there is every reason to believe that these also are becoming less fatal under the influence of sanitary measures. In preventive as in curative medicine, knowledge of causation is essential It is obvious that any rational system of proceeding must have this for its ham. A certain empirical knowledge may he useful as a guide, but no real advance can be expected with-out the exactitude which results from careful scientific observation and induction, the spirit of experimental re-earch, however, is now dominant, and progress is inevitable. How much we owe to it is already well known, whilst under its guidance the reproach of uncertainty which attaches to medicine as a science is dis or uncertainty which attaches to mentine as a science is dis-oppearing. Recent advances in physiology, chemistry, histology, and pharmacology, have done much to throw light on the nature and causes of, and also on the means of preventing or of dealing with, disease It is impossible to exaggerate the value of the scientific researches which have led to antiseptic methods of preventing the morbific action of micro organic life, whether the toxic effects produced by them, or those induced autogenetically in the individual Theory has here been closely followed by its practical application in prevention and treatment of disease, whilst the study of bacteriology, which is of such remarkable which may flow results of incalculable importance in their bearing on life and health That the conclusions arrived at are which may flow results of incalculable importance in their bearing on life and health. That the conclusups arrived at are always to be depended on I doubt, and it seems that scientific scal may perhaps sometimes outrun discretion. That it might lewiser to postpone generalization has, I think, been more than once apparent, whilst the expediency of further investigation before arriving at conclusions which may subsequently prove to be erroneous should not be lost sight of; but it has probably

"I'll va be bestored with regrets that during the last five years there have a studied by the last five years the relative to the studies of the last five years of the last whose this will grow only transviors, the statestors of santiary are moral of whateve may be the cause of it. I'm shown both by the vital moral of whateve may be the cause of it. I'm shown both by the vital energous assumpt of preventable where and death, but "I this the local manifelty profilions or local flucase causes are well known and wadeyveau."

— S. C. Nappen for 1896.

ever been so in the course of scientific progress, that in the enthusiasm of research, which is rewarded by such brilliant results, early generalization has too often been followed by disappointment, and it may be by temporary discouragement of

hopes which seemed so promising.

It would be well to bear in mind a caution recently given by
the Duke of Argyll, "that we should be awake to the retarding effect of a supersitious dependence on the authority of great men, and to the constant liability of even the greatest observers med, and to the constant manning of even use greatest observers to found fallacious generalizations on a few selected facts: (Nindeanth Cantury, April 1891) Still, it is in the region of scientific research by experiment that we look for real progress, and we can only deplore the mataken sentiment, the laise estimate, and the misconstruction of its sapirations and purposes, which have placed an embargo on experiment on living animals. watch naw places at entourpoon experiment on invine animans, rendering the pursuit of knowledge in this direction well much impossible, if not criminal; whilst for any other purpose, whether of food, clothing, ornament, or sport, a thousandfold the pain may be inflicted without question. The inconsistency of the sentiment which finds unwarrantable vullering in an operation of the proposition of the propositio performed on a rabbit, when the object is to preserve human or animal life or prevent suffering, but which raises no objection to the same animal being slowly tortured to death in a trap, or hunted or worried by a dog, needs no comment, whilst the spirit which withholds from the man of science what it readily concedes to the hunter is, to say the least, as much to be

It must be remembered that, important as are the researches into microbiology, there are other factors to reckon with before into microtology, there are other factors to reckon with before we can hope to gain a knowledge of the ultimate causation of disease. It is not by any one path, however closely or carefully it may be followed, that we shall arrive at a full comprehension it may be followed, that we shall arrive at a full comprehension of all that is concerned in it, etiology and prevention, for there are many conditions, dynamical and material, around and with us which have to be considered in their mutual relations and bearings before we can hope to do so, still, I believe we made that the cause of disease are now being more thoroughly sought out than they ever have been-all honour to those who are prosecuting the research so vigorously—and that though individual predilection may seem sometimes to dwell too exclusively on specific objects, yet the tendency is to investigate everything that bears upon the subject, and to emphasize all that is implied in the aphorism, Salus populi, suprema lex

The morning sitting of the Section and most of the afternoon sitting was devoted to papers and a discussion on "The Mode of preventing the Spread of Epidemic Disease from one Country to another."

another."
The chair was occupied successively by the President, Professor Brouardel of Fairs, and Prof. da Silva Amado of Lisbon Surgean-General Cuningham, of London, epened the discussion, and said the nodes of presention of spread of disease. from one country to another were three in number, (1) quaran-tine, (2) medical inspection, (3) sanitary improvements. In his remarks he dealt chiefly with cholera, and he held that the chief remarks as cent clienty with contern, and ne neit that the client factor of choleta, being carried by atmospheric currents, cannot be excluded from any country, and where it has been distributed over any area it excites the disease directly in many persons who are predisposed to it, and forms foci of it whenever it finds localities suitable for its increase, these are often very limited in extent, not embracing more than a single house, or even a portion of a house, or sbip, the mortality among the steerage passengers in the latter is often very great, the steerage passengers in the latter is often very great, while the cabin passengers and all the crew have scarcely a case. Such foot are always badly ventilated, and the emanations arising in them acquire much greater density than in the open air, as a natural consequence the clothing of those who reside in them about a momont of the emanation sufficient to produce cholera in susceptible persons outside until it has been dissipated by exposure, those so affected, however, and the other, who have contracted the complaint spart from such foci, do not seem to have any such influence, it being not the body but the emanations from the locality which generate the disease Cholers, therefore, cannot be excluded from any country by general quarantine. All that can be done is by hygienic measures to improve the health of the population, and to remove the conditions which favour the formation of foci The placing ships which arrive with cholera on hoard under observation, removing their crews and passen-gers to suitable localities on shore until the disease ceases among

them, are very proper precautions, and may prevent a small amount of the disease among the surrounding population, but can never prevent an epidemic if the necessary factors be in

Chin never present the progress Inspector General Lawson then followed with a paper on "The Communicability of Cholera from one Country to

To draw up a plan to prevent the extension of a disease, say cholera, from one country to another, with any prospect of success, it is necessary to have a general acquaintance at least with the different factors which contribute to the result, and of with the different factors which continue to the result, and of their mode of operation. The existing information on these points falls far short of these requirements, and its increase ha-been enormously impeded by the belief that man himself is the chief agent in diffusing the disease, and by interpreting the evidence obtained from various sources with an undue bias in favour of the theory There has been, in short, and still remains, a most serious error in assuming that personal communication is the principal factor, and a no less extensive error in the methods and reasoning by which the central idea of diffusion by man was advocated

The character and causes of cholera must be derived from a critical examination of all the evidence Nature presents, and from a study of the methods she hersell adopts, instead of from our a sutoy or me methods sile hersell adopts, instead of from our a press deduction. Cholera occurs in two different forms: simple cholera or cholera nostras, of little everetry, and attributed to local cases, and Assite epidemic, or malignant cholera, always a serious disease, and by many attributed to a possogreen of by those latouring under it to others, and so diffused

until it becomes epidemic.

Since 1832, when cholera visited Europe in the epidemic form, cholera nostrus has been observed to fluctuate every few years, and with the milder cases occur a certain number present-ing all the characters of the malignant disease, these cases occur singly or in small groups, but in every histance they accompany

pidemics of varying severity, at no very great distance off, and re under the same "epidemic influence"

Those who support the theory that man diffuses cholera are, necessarily, required to show that persons under the disease must arrive at points where it has not yet appeared, before it commences in these latter, and that the first attacks in the new locality have been in persons exposed to the imported eases: but there are now a good many instances of epidemics springing up in localities at a distance from where the disease was already prevailing, and without any trace of importation, and where those first attacked had resided in the country for many months in succession without communication with any previous case Such were the outbresks at Southampton in 1865, at New Orleans in 1873, and at Foulon and the south of France in 1884, all of which were most carefully investigated on the spot. The only other conclusion open was that the necessary factors were supplied by epidemic influence, and if supplied in one instance, supplied in all where there appeared to have been importation at the commencement of the outbreak, it must not be assumed that the disease was communicated by man unless the epidemic influence could be excluded, as at present it could not. It seemed probable that the exciting factors were conveyed by the air, whether fully or only partially developed, and consequently it was not in our power to exclude them; but much might be done by hygienic and other local means to limit their development in the localities they reached, and so to avoid

accessive moriality Thompson, official delegate of the Government of New South Wales, followed with a paper entitled "Quarantime in Australasia. Theory and Fractice." He said that the amount of traffic which had to be dealt with was an that the smooth of traine which had to be dealt with was as important consideration in all questions of practical quarantine. The Australasian Sanitary Conference of Sydney, N.S.W., 1858, was attended by delegates of each of the six Coverments, and by the speaker Their resolutions were unanimous, accepted by each Government, and pre-nieted to each Parliament. They had not been modified since 1854, and were therefore those received in Australasia at the present day. Limited quarantine tine, medical inspection, the outcome of England's local condi-tions, was exactly suited to them, but not necessarily suitable, therefore, where local conditions differed from England's. The theretore, where local conditions americal from England's. Lee first proposition of the Conference was that the deprive of protection which guarantine measures can afford varies inversely with the ease of communication between the sufected country and the country to be defended. The difference between English and Australisain conditions was described. The Conference rejected accined quaranties as a principle of action, and on account of easy and daily interchange of population between the use of a conference of a co

Dr. Rochard, of Faru (whose communication was read by Dr. Julea Bergron), said that the measo of preventing the traismission of spilemic diveases, such as the plaque, yellow fever, and hochera, were threfold—namely, robation, disinfection—and and the place of the place of the place of the place of the traismission of the place of the place of the place of the place It was also the most difficult to the place of the place of the place intervention of public enactioners, and the existence of an entact intervention of public enactioners, and the existence of an entact intervention of public enactioners, and the existence of an entact intervention of public enactioners, and the existence of an entact intervention of the second of the place of the place of the place tensity of the development of contemporary science. The high that when we had santary towns we could brave epidemics England had spent five millions wance the commencement of the entury, and it do not fear choicer danging the fast evidence. England had spent five millions wance the commencement of the entury, and it do not fear choicer danging the fast evidence. England had spent five millions wance the commencement of the entury, and it do not fear choicer danging the fast evidence England had spent five millions wance the commencement of the proceeded to detail the means taken as the fronter by the French anthorities during the last choicer applicance in Spain, and employment of liber nearests which responded to the meany taken future developed some better remedy.

In Sickonia, of Constantionities are mentioning the methodquarantine and impection, detailed by previous speakers, and that Turkey was like numerous other countries, one in which anitary organization had yet to be curried out. If Cholera has entered. Turkey in these last years by Busjonch (Persan Gulf) accord with the progress of sanitary science. The plignings of the Musualmans to Mecca, is also a great source of danger to the country. The laracted of Turkey ought to be made sanitary,

conditions are districtly output to be made animary. Dr. Hewitt, of Munestota, U.S. A, said they had very little to do in his State with disease properly called epidemic except that of small-pox. Choicer had but not one obtained something of a lodgment, and then it came directly from the port of New York ports of Egipand, and most of it came through the Culf of St Lawrence. Only the other day cases came from Liveppool to Mineseita. He mentioned one case in which inferion was carried in the dollaring of a form a highest on the refused in the College of the

demand was that there should be complete sanitary central organnation, with local organization in direct (calcium thereto, and parameters are considered to the constraint of the conquarantine service, which should be bound to give notice to the interior authorities of the presence of disease. On Infection, and that they should all on course for its contract or infection,

Dr Simpson, of Calcutta, stated that the real source of cholera epidemics in Europe was, in his opinion, from emigrants and pigrams coming over land and in ships to Mecca, where there was a focus 2000 miles nearer Europe than any Indian port. Dr Leduc, of Nantes, agreed with Dr Cunnigham as to the

Dr. Ledwe, of Nantes, agreed with Dr. Chinngham as to the need of improved santary contitions in our forms, but he strongly disagreed with him when he proposed the suppression of quarantine. Modern science teaches us that contagous discases are spread by wandering germs isolation must therefore he a preventive to the spread to the disease, and quarantine the suppression of quarantine was to propose a measure at one that the proposed of the proposed of the proposed of the restriction of the proposed of the proposed of the proposed previously district the proposed of the proposed of the proposed previously district the proposed of the proposed of

Dr. Thorne Thorne, of I ondon, spoke of the need of sanitary reform in towns, and depretated the so called protection of a country by means of cordons, quarantine, &c. The sixteen days' quarantine decided at Constantinople in 1866 failed, the ten days' quarantine decided at Vienna failed, and yet the five days' suggested at Rome is to succeed. The contention is altogether illogical.

Frot. Stelvers, of Amsterdam, said that at the International Medical Congress at Ansterdam there was a discussion on quaranties, in which the same arguments for and against wer and the same arguments for and against were supported to the same arguments for any supported to the same arguments for any supported to the support of predemic discusses, and especially of cholera, was to make sanitary improvements. If the had arrived at this conclusion by the study state have improved the same arguments of the same arguments and the same arguments and the same arguments are the same arguments and the same arguments are supported to the same arguments and the same arguments are supported to the same are supported to the same arguments are same arguments are supported to the same argum

These facts taken together amount to a presumptive case against
one or other of these parasites as the cause of sleeping sickness.
The probable life-interies of these worms is then indicated,
the Filarin los being considered the parental form, and an inthe Pilaria lea being considered the parental form, and an in-sect, called the mangrowe fly, the intermediary host of Pilaria is hairna. The parental form of Filaria is h fertilaria is not known, but, assuming that the worm of craw craw, skepping suckness, and dermalous parantaire is the same, and that the skin form a an advanced stage of the embryo filaria found in the skin form is an advanced stage of the emoryo mara found in the blood, then, arguing from the analogy to what happens in the case of the embryo of Filaria mediumsis, which closely resembles this skin parasite, the probable intermediary host of re-embles this skin parasite, the probable intermediary host of Filaria 1 h gerdian: as freshwater animal, possibly a cyclops, Provided the hypotheses as regards there parasites and the diseases they produce are correct, both divesse and parasites may be avoided by securing a pure water supply to which the intermediary hosts of the parasites do not get acceptable to for assistance in cleaning up the subject, and for further in for assistance in cleaning up the subject, and for further in

An appendix to the paper contains directions for demonstrating in the surest, most rapid, and most effective way the presence or absence of filaria embryos in blood, and of making collections of slides of blood for storage and future examination Dr Sonsino, of Pisa, made a few remarks on Dr Manson's sper The meeting then adjourned.

On Wednesday, August 12, the chair was occupied suc-cessively by Sir Joseph Fayrer, Dr Pistor of Berlin, and Surgeon General Roth of the Saxon Army

DISCUSSION ON DIPHTHERIA

Dr. Edward Senson, of Londou, opened a dicension on "Diphiens, with opened reference," and distribution and to the need for comprehensive and systematic inquiry into the causes of its prevalence in certain countries and parts of countries, with a view to its prevention."

Dr. Seaton and that he should confine himself in introducing

Dr. Seaton and that he should confine himself in introducing in subject to leading statements, showing the necessary for competeness and systematic inquiry to be pronoted by Govern countries and parts of comprise, with a view to its prevention. He first of all pointed to the special prevalence of the daesae, as shown by Ir. Longstaff, in Norfolks and Wales, and the foundation of the control of the daesae, are the disease prevailed more in He then dwelt on the facts that the disease prevailed more in rural than urban districts, although it has shown of late years an increasing preference for urban populations, especially that of London. He showed the independence of the disease of what are ordinarily called vanistay conditions, and illustrated that by a table taken from Dr Thorne Thorne's recent electures at the Royal College of Drystanas, showing the fall in enteric fewer mortality in Bigland and the College of Drystanas, though the con-tinuation of the College of Drystanas, though the fall in enteric fewer mortality in Bigland and the College of Drystanas, though the con-tinuation of the College of Drystanas, though the College of Drystanas, the College of Drystanas, though the College of Drystanas, the College of Drystanas, though the College of Drystanas and D mortatily in England and wates which had spinchfolized with a rate in the mortality from diphthers. He further what are usually termed sanitary conditions by experiences gathered from a large manufacturing town in the Midlands, and from certain parts of the metropolis in which he had special opportunities for observation as a medical officer of health, as well as in connection with the work of the Metropolitan Asylums well as in connection with the work of the Metropolitan Asylums Board, into whose hospitals cases of diptherins had been re-bened to the most of the most of the most of the con-experience of a Surrey village, in which the disease had pre-valled in an epidemie form, shortly after the replacement of the old insanitary cesspool system by a new and elaborately con-structed sewerge system. The occurrence of the disease under these circumstances gave rise to the suspicion that there might be a connection between diphtheria and conditions of soil, which needed to be investigated in a comprehensive and systematic manner, to be investigated in a comprenensive and systematic manner. In conclusion, he pointed out the importance of these main considerations, viz. (t) the prevalence of the disease in strakingly different degree in countries in the same latitude and with similar climatic conditions and also in parts of countries close to each other, (2) the fact that it has not apparently been influenced favourab by the adoption of sanitary measures which have been generally

found effective in reducing the death rate, prove the necessity for a comprehensive inquiry by our own Government as well as those of other countries, into the causes which determine the prevalence of diphtheris. Such an inquiry should take into those of other countries, into the causes which determine the prevalence of diphthers Such an naquity should take into account what has already been ascertained with regard to the occasional causation and spread of the disease by milk, and the influence which schools have on its production and spread, and also the subsidiary influence of deimpness, dirt, overcrowding, &c ; but its main object would be to ascertain the local ing, &c; but its main object wouls doe to ascertain the local conditions and circumstances who caccount for the growth of the disease. To ascertain these the inquiries must, of course, be made in countries murked by freedom from the disease as well as in those which suffer from it specially. Dr. Schrewen, of Tournai, followed with a paper entitled "Contribution a Fétude des cases arounant les endemles diphehériques," of which the following is an abstract

By investigating carefully how the ravages committed by diphtheria are distributed over the different districts, one can diphtheria are distributed over the different districts, one can attain more easily to a presets knowledge of the external conditions which favour the barbouring of diphtheritic germs, and which result in such germs heng frought into a locality. In-different control of the co ravages the same fact was observable in the case of diphthems; and that when ehiphthems secured its smallest number of vectors the number of deaths caused by typhool fever diministration of the control march of diphtheria and typhoid fever stands out clearly On what does this relation, this agreement rest? On this fact, that these two diseases must be considered as feecal diseases, as B. these two diseases must be considered as feecal diseases, as B. Russell, of Glasgow, has remarked The bacilli of Loffer, like the bacilli of Eberth, develop admirably, prosper, and extend wherever filth and rubbish of all kinds are stored up or spread out, there exists, however, this slight difference between the conditions which are severally favourable to them impurities on the surface of the soil suit the bacilli of Loffler in a special degree, while impurities of the subsoil please the bacilli of erth better.

Even the exception formed by East Flanders tends to confirm this rule, masmuch as it is perfectly clear that its surface ought to be more easily cleared of all impurities by reason of the to be more easily cleared of all imparities by reason of the numerous watercourses which furrow it. A further proof that it is, in a special degree, impurities of the surface which serve to harbour diphtheritic germs in certain localities, is the exaggeration of mortality from diphtheria in country distincts compared to what obtains in towns, density of the population is not of the least influence on the increase of the mortality due to diphtheria, but the surface of the soil is much better protected in towns against impurities of all kinds

Another circumstance which may foster diphthena in a locality Is the breeding of certain species of animals presenting a great receptivity for diphtherogenic germs for example, Italian fowls and game-cocks. The transmission of diphtheria to man by these animals is so well established by the observations colthe the salimans is so were examined by the observations con-lected by the author for several years past that he feels per-suaded of the need of further attention being paid to this subject. Finally, a third condition which necessarily fosters diph-theria in a locality is the aegligence exercised in the application of measures of disinfection and holdation.

Every case of diphtheria must be notified to the local anthority, who will see to it immediately that all the children anthority, who will see to it immediately that an the cinieren of the sick periods family be kept away from school as long as any danger of contegion exists. In every case distribution must be ragorously attended to and performed by special agents. Notification and disinfection ought to be obligatory. The altitude of the locality does not probably exercise any very great influence. One would suppose that diphtheris would be specially prevaient in low, damp pixees. Recent observations are considered to the content of the content of the speciality prevaient in low, damp pixees. Recent to be specially prevaient in low, damp pixees.

very great influence. One would suppose that depintheria would be specially prevalent in low, damp places Recent observations by the author on the progress of diphtheria in three contiguous parishes of the district of Ath (Eadeghien, Ostiches, and Mainvault), show that in each of these parishes there was a

principal seat of the malady, and that in the three parabes this seat was in precisely the most elevated hamlet of ill, a fact which from the first appears somewhat strange. One may, perhaps, conclude that Loffler's bacillus does not like too much damp, and that it is in this respect that its character differs from the bacillus of Eberth

Dr. Hewitt, Secretary and Executive Officer of the State Board of Health of Minnesota, U.S.A., said that his experience covered eighteen years of saultary service with the disease in an interior State of the American Union with a very complete public health service, consisting of 1575 local hoards of health, with a State Board Notification of infectious disease by physicians, householders, hotel and inn keepers, has been obli gatory since 1883 with penalty, as is also isolation and dis-infection by the local boards of health. The facts believed to he proven in Minnesota were that the disease is very infectious, that it is communicable by persons and things, that the infectemperature, that it is very tenacious of life as against measures of disinfection, and lives for long periods in clothing and bedding and on floors and walls. Isolation and systematic disinfection. and on noors and wans. I solution and systemace distinctions with the most perfect sanitary regulation, are most efficient at present in the control of the disease. Since these had been in efficient use the prevalence had assumed a family character, limiting itself to one or more associated families, and rarely hinting stieff to one or more associated families, and rarely going beyond, except by erasion of the law on the part of an infected person. What was needed now was more careful facts of each outbrack with a very to a more accurate knowledge of the disease, not neglecting the perenties and controlling measures now found to be most theness, as above. Dr. Jules Bergeron, of Parss, followed with a paper entitled with the measures plate that Dr. Jules Bergeron and the state of the person said what the measures plate that Dr. Jules Bergeron said what the measures plate that Dr. Jules Bergeron said what the measures plate that Dr. Jules Bergeron said what the measures plate that Dr. Jules Bergeron said what the measures plate that Dr. Jules Bergeron said what the measures plate that Dr. Jules Bergeron said what the measures plate that Dr. Jules Bergeron said which we have the proposed to the proposed to

that the measures to be taken against diphtheria were disinfec-tion and isolation disinfection of all clothing, &c, contamition and solution disinfection of all clothing, &c, contaminated with secretions from the affected pair, isolation of all cases and of all doubtful cases, such as those of a herpetic character, which are difficult to distinguish from diphiheran in the early stage of the disease. An important question to be answered is, How long ought isolation to continue, how long, in fact, does contagion last? Dr. Bergeron says that he adopts so weeks' isolation as the maximum, and that he has never observed a case of transmission of the disease when a case has been isolated

for this period.

Dr Gibert, of Havre, spoke of diphtheria in Havre Dr. Gibert, of Havre, spoke of diphthera in Havre Hot and that diphthera appeared in Havre shout 1866, it there was an innited to the Graville Justicer in 1866, there was an innited to the Graville Justicer in 1866, there was an innited to the Graville Justicer in 1866, there was an innited to the Justicer in 1866, there was an innited to the Justicer in 1866, there was an innited to the Justicer in 1866, the Justicer in 1866, the was a fine death content of the disease increased until 1885, when a singuist de sinishrild was formed as an annexe to the Bureau distingtion of 1867, the divellings occupied by diphtheric patients d'Hygiène The dwellings occupied by diphtheritic patients having been regularly disinfected, the mortality curve has since decreased to such an extent as to justify the hope of its total extinction, provided all the medical men of the town furnish accurate information to the Bureau d'Hygiene

Dr. S. W Abbott, of Boston, U.S.A., read a paper on "Diphtheria in Massachusetts from 1871-88." From his observations he concludes that diphtheria is an eminently contagious disease, that it is infectious, not only by direct exposure of the sick to the well, but also through indirect media, such as clothing and other articles that have come in contact with the sick; ing any other actions may be some as in the case of some of the other infectious diseases, notahly small-pox and scarlet fever. Dr Abbott also concludes that overcrowding, &c., favours the spread Abbott also concauses that overcrowing, &c., favours the spread of the disease, but that its transmission through the water supply is not proved. Its transmission is favoured by soil-mosture and dump houses, and the poison may remain infective to hosses for a long period.

If the district of the distr

the Morement of the Subsoil Water." The conclusions he arrived at were that the organism of diphthers inshins organi-ally polluted surface-soil, and that, subject to suitable conditions and the subsection of the subsection of the subsection of the food, it threes and multiples in the soil, the superment, and thus produced being liable to displacement from the sitemines of the polluted surface soil, and to dispersal into the appear-nments of the polluted surface soil, and to dispersal into the superm-cambout air; in this manner detertialing outbreaks of the disease. So that, given the existence of the publique form, two sets

of factors at least are engaged in the production of a state of affairs that culminate in an outbreak of diphtheria First, those that promote and support the growth of the germ in the soil. such, for instance, as moisture, temperature, air, food, and so on Secondly, agents of dispersal, by which the germs already existing in the soil are driven out and distributed into the atmosphere, and so come to be breathed by man and animals, for example, sudden rainfall, rise of subsoil water, lowering of barometric pressure
Mr Charles E Paget, of Salford, followed with a paper on

"A Local Examination of the Difference in Susceptibility between Old and New Residents"

The general conclusion at which he arrived as the result of an The general conclusion at which ne arrived as the result of an aximation of the statistics of Salfori was, that a shorter average period of residence before an attack of diphtheria was observed where the general mortality rate was highest and once word, that, in fact, the relative incidence of diphtheria during an epidemic period, in respect of length of residence, was de-

an epidemic period, in respect of length of resucence, was de-pendent to no small extent on general santary circumstances. Prof. D'Espine, of Geneva, foll-wed in the discussion. He drew attention to the great value in the prophylaxis of diphtheria, in the systematic washing out of the mouth and pharynix by antiseptic solutions, corrosive sublimate (t in 10,000), salicylic acid (r in 2000), and line juice In his practice he used salicylic

acid (it in 2000), and linne juice
In his practice he used salicylic
acid in the strength of 1 j to 2 per 1000
Dr Tripe, of Hackney, who followed, said he had had large
experience of this disease, as he had been 35 years Medical
Officer of Health in Hackney
During that time all deaths had
been investigated, and lately all cases, with the result that there was no evidence that insanitary conditions of houses caused the disease, although they might predispose to it. He believed that closing playgrounds in schools is as effectual in checking the disease as closing the schools, that prompt removal to hospital and disinfection of clothing and rooms, burning of infected rags, &c., are the best methods for checking the disease.

Dr Thursfield, of Shrewsbury, agreed with Dr Hewitt that dampness had a great deal to do with the citology of diphtheria, he had lumself stated so thirteen years ago in a series of papers on the subject. He thought Dr. Adams's conclusion regarding the connection of the rise and fall of the subsoil water with out-

the connection of the rise and tall of the subsoli water with out-breaks of diphtheria a somewhat hasty generalization. Dr. Gunther of Dresden, Dr. Janssens of Brussels, Dr. Hubert of Louvain, Dr. Escherich of Graz, Dr. Jules Felix of Brussels, and Dr. P. Sonsino of Pisa, also took part in the discussion, many of the speakers emphasizing the need of local anticeptic measures in the prophylaxis of diphtheria.

anticeptic measures in the prophysics of dipinteria. At the end of the discussion, the following recommendation was unanimously adopted by the Section —
"That this Section urges the European Governments to make a comprehensive and systemative inquiry into the causes of diphthera."

On Tuesday afternoon, Sir John Banks, K.C.B, and

Overlacge Bentzen, Christiania, occupied the cliair, DISCUSSION OF THE PREVENTABILITY OF PHILIPSIS.

Dr Arthur Ransome, F R.S., read a paper "On the Need of Special Measures for the Prevention of Consumption." He said, that consumption is both curable and preventable will be acknowledged at once by all medical men who have had any experience of modern methods of dealing with the disease.

experience of modern methods of deathing with the disease. Its currishinty is attested (if) by the reports of many pathologists as to the presence of evidence of healed phthiss in a large proportion of bodies examined in public institutions. Many thousands of such examinations have now been made, and the unousants of such examinations have now been made, and the results show that from 25 to 50 per cent of persons dying from other diseases than phthats give signs of spontaneous cure of tubercular disease. (2) The tectimony of all the most eminent modern physicians is to the same effect, that consumption is distinctly curable

With regard to the preventability of the disease we have also a strong basis for our faith.

a strong basis for our tain.

(i) In the marvellous results that followed the improved dramage and ventilation of the harracks of the British army in all parts of the world. Before the year 1842, the mortality from lung disease amongst the picked population of these dwellings was a scandial to the nation, and was enormously greater than that of the ordinary inhabitants of our towns, especially in the battalions sent to warm climates, such as those of India, Ceylon, the West Indies, the Mediterranean, &c.

Thanks to the above mentioned measures, it now stands at

from one-third to one-tenth of its former rates.

(2) The influence of improved drainage has been shown by (a) The influence of improved dramage has been shown by T Buchanan, in his table of towns, contrasting the mortality by phishas and other diseases before and after the introduction of the general phishins rate of the country from agoo per 1,000,000 in 1867, to 1500 per 1,000,000 in 1889. My own observation in Manchester and Salford, and those of Dr. Tiven in Oldham, and of Dr. Tiven in Philadelphia, and of Dr. Tiven in Philadelphia, and of the property of

bouses. Under these circumstances it seems to me that the duty of sanitary authorities is clear. They should regard pithusis as a disease to be dealt with on precedy the same lines as the analogout diseases, typhoof fever, clotter, and feyour,—disease which spread by material throws off from the bodies of the patients. The means to be employed to thus end would also be very similar of 10 notification of cases, 2) disintalection, (3) loopital accommodation, and (4) general sanitary measures, such as ventilation, dranges, and reconstruction of unhealthy

(1) Notsheatron -At first it may sound somewhat novel to (1) Notification —At Inst it may sound someware moves to demand that a slowly progressing alment like phihus should be notified as if it were liable to become an epidemic disease, but, after all, we may fairly inquire whether the purpose of notification is not the prevention of any disease that could be arrested by early intelligence of its existence being sent to the health officer, nor would there be much difficulty in oblaming. the notification of phthisis Although phthisis is not directly contagious, there would be nothing uttreasonable in classing it with other diseases that need special measures to prevent its

(a) Distinction.—After recoving notice of a case of tubercules, the next step to be taken by a local authority would be to accratian whether proper care is or can be taken to preven the proper care is or can be taken to preven the information is given by the metical attendant would be said faceat, but where the case is that of a poor person it should be sufficiently but where the case is that of a poor person it should be sufficiently and the sufficient of the premises, and to the disposal of distinction by subplier and the steaming of dolbest should be carried out. Paper spintons that can be burnt should be instead upon After death, also, measures should be taken for the deating and dissification of house, bedding, and clothes the deating and dissification of house, bedding, and clothes question of the propriety or possibility of removing the sick (2) Disinfection .- After receiving notice of a case of tubercu-

(3) Hayifal Accommodation — Their would next come the question of the propriety or possibility of removing the sick person to hospital. So long as he for she) could work, and so remove the property of the property of the property of the more than I have aiready indicated; but when the patient becomes unable to follow his employment; and the family are obliged to acek for assistance from the parith, he has a claim to be received into the workhoose hospital, and such an anytim abould be offered him, and should be made as little humiliating and as free

from ignominy as possible
(4) But it is probably to general sanitary measures that we (4) but it is prousing to general same and mortality from tubercle

It has been found that deep and thorough drainage of the subsoil will greatly diminish this mortality. of Salisbury, as you are probably aware, it was reduced by one-half, and similar reports have come from other towns, and though the same result has not always been obtained elsewhere, there can be no doubt as to the importance both of draining and concreting the foundations of dwelling houses, so as to prevent organic vapours from rising along with the ground air

into living-rooms.

It is for this reason that I have ventured to suggest that where consumption is prevaled there must exist some special numment which either (t) serves to prolong the life of the bacillus.

retain its power for evil much longer than when it was exposed to some fresh air and light.

It is possible that these may be regarded as somewhat strong proposals, but at least they have the merit that they may all be proposals, but at least they have the ment that they may an up to flore without any material increase in the powers now possessed by local subhorities. The only thing needed to enable them to be carried out in their entirety is a powerful public opinion to back them up. When people generally, and especially the working classes, realize that a large part of their distinguishment. celly the working classes, realize that a large part of their side ness and consequent loss of time and money is due to their ness and consequent loss of time and money is due to their neglect, they will unquestionally be on our side. The under-taking possesses, moreover, the further ment that not only will all this sanitary improvement prevent consumption and other tothercular diseases. by doing away with the sources of infection, but it will also prevent them by raising the general standard of health amongs town dwellers. It will so strengthen those who are already predaposed to the disease that they will more rankly throw of any stray germs of tubercle that may find an entrance into their bodies. conduce to spontaneous care, will prevent recurrence of the Of Soil on the Spread of Tuberculous Diseases "On the Influence of Soil on the Spread of Tuberculous Diseases"

He showed on a large map of Germany that the localities where phthisis was most prevalent were those in which there was a printing was most prevaient were those in which there was a moory soil with signating and high-standing ground water, such as aome districts in the north western provinces, in the Rhenish province, in Upper Basira, and in some parts of Silesia These facts agree with the conclusions of Bowditch and Buchanan Overcrowding did not appear to have much

and Buchanan Overcrowding did not appear to have much influence on the spread of philisis.

Dr. J. Edward Squire, of London, read a paper entitled, "To what extent can Legislation assist in diminishing the Prevalence of Consumption and other Tubercular Diseases."

Dr Squire considered that the danger of infection increase In Squire considered that the danger of intection increased with the close crowding of the sick and healthy, and with def-cient ventilation, and that by sanitary improvements this danger might be obviated. There ought also to be a proper supervision of food (meat and milk) obtained from tuberculous cattle. I rade

of food (meat and mulk) channel from tuberculous cattle. I rade an relation to philms were also discussed.

Dr. Gibert, of Havre, followed with a pater entitled "De is distribution geforaphague de la Unitario phinoasite dans la description of the proposition, avec l'alcoolume, et avec la musice "Dr Gibert thought from houberrations that overcrowding was a great factor in the etiology of phihms but that a leoholism played a much greater part, and poverty was also a factor ! If showed on a map the distribution of phihms in Havre Sr John Banks, of Dahlin, who spoke in the discussion, Sr John Banks, of Dahlin, who spoke in the discussion,

mentioned that the sanitary improvements undertaken in Dublin had produced a great diminution of disease Practice both in hospital and private had demonstrated this to him. Mr Weaver, of London, and Dr B O'Connor also took

part in the diacussion.

"Bibliotheca Botanica," illustrated by eleven fine plates, by Herr G. Karsten. Herr Karsten points out that, in addition to the obvious mechanical function of these roots, serving as a supporting organ to attach the trees more firmly to the very loose soil in which they grow—this is especially observable in Rhitsphora mangle—there is another important function performed by them, at least in a large number of the trees which formed by them, at least in a large number of the trees which make up the mangrore-regulation, though I do not recollect that Assessment in the specially mentioned. In the specialline scannined by Karsten, these aerial roots possess very large intercellular spaces, which serve to promote the interchange of gases, and he considers it unquestionable that their chief function is to and in commers it unquestionance that their caler function is to assist respiration. He therefore proposes for them the term "pneumatophores." It would be interesting to examine the structure of the trees at the Botanic Garden in this respect All mangrove-trees also contain large quantities of tannin, which is probably serviceable in pieventing folling.

The Tasman Sea

I SEND you the inclosed copy of a letter from the Secretary of the Admiralty, in case you should consider the matter of sufficient interest for notice in your columns.

A. LIVERSIDGE, Permanent Hon Sec

Australasian Association for the Advancement of Science

The University, Sydney, July 4.

Admiralty, May 19, 1891 SIR,—With reference to your letter of March 17, forwarding copy of a resolution passed by the Australasian Association for the Advancement of Science at the meeting held at Christchurch, New Zealand, that the name of Tasman Sea should be given to the sea between New Zealand and the islands of the north-west the sea between New Zealand and the islands of the north-west of New Zealand on the one hand and Australia and Tasmania on the other, I am commanded by my Lords Commissioners of the Admiralty to acquaint you that the name will be inserted in Admiralty charts and other publications.

I am, Sır, Vour obedient servant.

EVAN MACGREGOR. To Prof. Liversidge, M A , F R S , The University, Sydney

Reduplication of Seasonal Growth

LAST summer I sent you a note on the occurrence of apple-blossoms and the blossoms of the mountain ash in July. Before bossoms and the consoners of the mountain and in July.

Before me now, as I write, is a simple but elegant bouquet containing a beautiful and fragrant coryinb of the latter tree in full flower, side by side with one of the ripe scarlet fruit, which the blackbirds have begun to devour

These were cut from one and the nica have beguin to devour. These were cut from one and the self-ame tree this morring at the top of my garden, while from the self-ame tree that the self-ame tree that the self-ame tree the leaves from which all the chlorophyl has disappeared, the phenomena which mark the beginning and the end of the season thus appearing side by side. These trees grows on the Upper Baghot Sinds, and I have no doubt that this reduplectuon of sonal growth is due to the later rains developing some centres of flowering energy in the plant, which had remained dormant during the spring owing to deficiency of moisture and warmth. Wellington College, Berks, August 17. A. IRVING.

Rain-gauges.

I HAVE been using the ordinary Symonds pattern rain-gauge, but find that the percentage of rain collected varies in proportion to the strength of the wind; when this is moderately strong, smoot the whole of the rain passes across the top, strating and being retained by vertical surface only.

The present method of estimating the rainful is far from state to correct or uniform, and I should like to ascertain if which correct or uniform, and I should like to ascertain if

any gauge has been made with a correctly-proportioned inverted cone, which will collect and compensate for side drive, and, if so, what are the correct proportions. It would appear that cither this, or a fannel mounted on glabals and balanced to face the wind at the correct angle, must be the only correct method to accertain the actual rainfall. The present apparatus would appear to be crude, untrustworthy, and incapable under any conditions in practice of giving results which are at all trust-THOS FLETCHER. Grappenhall House, Grappenhall, near Warrington. August 17

THE BRITISH ASSOCIATION

(FROM OUR CORRESPONDENT.) CARDIEL, Wednesday Morning

THE preparations of the Local Committee are now in an advanced state, and members of the Association are beginning to arrive in considerable numbers

A change has been made in the position of the Recep-tion Room, which is now located entirely in the Drill Hall, the Town Hall having had to be abandoned for that purpose owing to the impossibility of making adequate provision for the accommodation of the large number of guests expected The Drill Hall is a large building, and has been divided into two parts by a screen, which also serves the purpose of a notice-board. On the entiance side are the offices for various purposes, post and excursions : and at a central oval counter, all other requirements relating to tickets, reserved seats, publications, and lodgings are attended to by a numerous staff of clerks

Beyond the screen the hall has been fitted up as a drawing-room, and from this lead off smaller from the drawing-room by a passage is the gun room, from which were things has been removed, and tables laid down so as to convert it into a dining-room

The President's address will be given in the Park Hall, this evening, and for the half hour of waiting before the business commences Mr T E Avlward will give a recital upon the fine organ in that hall. It is understood that Lord Bute, as Mayor of Cardiff, will at the outset welcome the Association in the name of the town of Cardiff.

The conversazioni will also be given in the same hall, and from 8.30 to 9 pm, Lord Buie, as Chairman nail, and from 3,0 to 9 pm, Lord Dile, as Chairman of the Local Committee, accompanied by Lady Bute, will receive the guests At 930 pm an exhibition of views will be given by the lime-light, amongst them some fine ones, by Mr M Stirrup, of the limestone region of fine ones, by Mr M Surrup, of the Immesione region of Languedoc. Amongst other attractions will be taking impressions of finger-tips, by Sergeant Randall (Mr. F. Astronomer-Royal of Scodinal, dawings in black and white of the Himalayas, by Col Tanner; a collection of local maps and adlates, by Mr O H. Jones; the Esteddfold concert given at Swansea transmitted by the Charles of t of interest.

Arrangements have been made for military and vocal

No alteration has been made in the Section rooms from that mentioned in our former article

The publications of the Local Committee are ready for distribution, and comprise the local hand-book of 240 pages dealing with the archeology of the land of Morgan, the education, botany, geology, industries, and topo-graphy of Cardiff; the excursions-guide containing a map of the district on a scale of four miles to the inch, and two maps on a larger scale, one of the Bute Docks, and the other of the Barry Dock The excursions number twenty in all—twelve are arranged for Saturday, the 22nd, and eight for Thursday, the 27th, and moderately detailed descriptions of each are given in the guide to the excursions.

The local programme, and the list of lodgings and hotels, are the remaining publications of the Committee. The total number of members of all classes who have taken out tickets for the meeting was, at 6 p.m. yesterday,

The President's address is as follows '-

INAUGURAL ADDRESS BY WILLIAM HUGGINS, ESQ., D.C.L. (OXON.), LL.D. (CANTAB., EDIN., ET DUBL.), PH.D. (LUGD BAT.), F R S, F R.A.S., HON F R S.E., &c., CORRESPONDANT DE L'INSTITUT DE FRANCE, PRESIDENT.

It is now many years since this Association has done hos to the science of Astronomy in the selection of its President. Since Sir George Airy occupied the chair in 1851, and the late Lord Wrottesley nine years later, in 1860, other aciences have been represented by the distinguished men who have

have been represented by the distinguished men who have presided over your meetings. The very remarkable discovernes in our knowledge of the heavens which have taken place during this period of thiny branches of science—have not passed unnoticed in the addresser of your successer Persidents, still it seems to me fitting that I should speak to you to-might chiefly of those newer methods of attributional presents which have led to those discovernes, and which have become possible by the introduction since 1850 into the observatory of the spectroscope and the modern plotagraphic plate

plate
In 1866 I had the honour of bringing before this Association,
at one of the evening lectures, an account of the first fruits of
the novel and unexpected advances in our knowledge of the
celestial bodies who followed rapidly upon Kirchhoff's original
work on the solar spectrum and the interpretation of its lines.

Since that time a great harvest has been gathered in the same field by many reapers. Spectroscoper astronomy has become a distinct and asknowledged branch of the sciences, possessing a large interature of its own and observatories specially devoted to it. The more recent discovery of the gelatine dry plate has given a further great impetus to this modern side of astronomy, and has opened a pathway into the unknown of which even an enthusiast thirty years ago would scarcely have dared to dream.

In no science, perhaps, does the sober statement of the results which have been achieved appeal so strongly to the imagination, which have been entieved appear so strongly to the imagination, and make so evident the almost boundless powers of the mind of man. By means of its light alone to analyze the chemical nature of a far distant body, to be able to reason about its present state in relation to the past and future, to measure within an English mile or less per second the otherwise invisible within an English mile or less per second the otherwise invivible motion which it may have towards or from us, to do more, to make even that which is darkness to our eyes light, and from vibrations which our organs of sight are powerless to perceive to evolve a revelation in which we see unirrored some of the to evolve a revelation in which we see mirrored some of the stages through which the stars may pay in their slow evolutional progress—surely the record of such achievements, however poor the form of words in which they may be described, is worthy to be regarded as the scientific epic of the present century.

I do not purpose to attempt a survey of the progress of spec-troscopic astronomy from its birth at Heidelberg in 1859, but to point out what we do know at present, as distinguished from what we do not know, of a few only of its more important prob-lems, giving a prominent place, in accordance with the traditions of this chair, to the work of the last year or two.

In the spectroscope itself advances have been made by Lord Rayleigh by his discussion of the theory of the instrument, and by Prof. Rowland in the construction of concave gratings.

Lord Rayleigh has shown that there is not the necessary con-nection, sometimes supposed, between dispersion and resolving power, as besides the prism or grating other details of construction and of adjustment of a spectroscope must be taken into

The resolving power of the prismatic spectroscope is propor-tional to the length of path in the dispersive medium. For the heavy flint glass used in Lord Rayleigh's experiments, the thickess necessary to resolve the sodium lines, came out 1'02 cm. If this be taken as a unit, the resolving power of a prism of similar glass will be in the neighbourhood of the sodium lines. similar giass will be in the neighbourhood of the sodium lines equal to the number of cenimieres of its thickness. In other parts of the spectrum the resolving power will vary inversely as the third power of the wavelength, so that it will be eight times as great in the volet as in the red. The resolving power of a spectroscope is therefore proportional to the total thickness of the dispersive material in use, irrespective of the number, the of the dispersive materias in use, irrespective or tire number, sine angles, or the setting of the separate prisms into which, for the sake of convenience, it was be distributed. The resolving power as a grating depends upon the total number of lines on its surface, and the order of spectrum in

use; about 1000 lines being necessary to resolve the sodium lines in the first spectrum.

As it is often of importance in the record of observations to

As it is often on importance in the record or observations to state the efficiency of the spectroscope with which they were made, Prof Schuster has proposed the use of a unit of purity as well as of resoluting power, for the full resolving power of a spectroscope is realized in practice only when a sufficiently harrow all it is used. The unit of purity also is to stand for the separa-tion of two lines differing by one-thousandh of their own wavelength , about the separation of the sodium pair at D.

A further limitation may come in from the physiological fact that, as Lord Rayleigh has pointed out, the eye, when its full aperture is used, is not a perfect justrument. If we wish to realize the full resolving power of a spectroscope, therefore, the emergent beam must not be larger than about one-third of the

opening of the pupil

Up to the present time the standard of reference for nearly all op to the present time the samulation reversible to meany an spectroscopic work continues to be Angastróma map of the solar spectrum, and his scale based upon his original determinations of absolute wave-length. It is well known, as was pointed out by Thalen in his work on the spectrum of iron, in 1884, that Angstrom's figures are slightly too small, in consequence of an error existing in a standard metre used by him. The corrections for this have been introduced into the tables of the wave-lengths this Association from 1885 to 1887. Last year the Committee added a table of corrections to Rowland's scale

The inconvenience cansed by a change of standard scale is, for a time at least, considerable, but there is little doubt that in the near future Rowland's photographic map of the solar spectrum, and his scale based on the determinations of absolute wave length by Pierce and Bell, or the Potsdam scale based on original determinations by Muller and Kempf, which differs

very slightly from it, will come to be exclusively adopted
The great accuracy of Rowland's photographic map is due

The great accuracy of Rowland's photographic map is due therefly to the introduction by him of concave graining, and of a method for their use by which the problem of the determination of relative wave length as sumplified to measures of coin. The concave graining and its peculiar mounting, in which he lenses or telescope are needed, and in which all the spectra are infects together, formed a new departure of great importance in the measurement of spectral intens. The valuable method of photographic enusiren for different parts of the spectrum has canalled Froft Rowland to include m his map the whole vanible solar spectrum, as well as the ultra-violet portion as far as it can get through our atmosphere. Some recent photographs of the solar spectrum, which include A, by Mr George Higgs, are of great technical beauty

During the past year the results of three independent researches have appeared, in which the special object of the obsearches have appeared, in which the special object on the ob-servers has been to distinguish the lines which are due to our atmosphere from those which are truly solar—the maps of M Thollon, which, owing to his lamented death just before their final completion, have assumed the character of a memoral of

him, maps by Dr Becker, and sets of photographs of a high and a low sun by Mr. McClean.

At the meeting of this Association in Bath, M. Janssen gave an account of his own researches on the terrestrial lines of the solar spectrum which owe their origin to the oxygen of our atmosphere He discovered the remarkable fact that, while one atmosphere He discovered the remarkable fact that, while one class of bands varies as the dentity of the gas, other diffuse bands vary as the square of the density. These observations are in accordance with the work of Egoorf and of Ussewist, and of Liveng and Dewar on condensed oxygen. In some recent repersents Observable, with a layer of liquid oxygen concludent with Franshofer's A; a remarkable instance of the measurement of the proportion through a remarkable instance of the measurement of shootton through a remarkable instance of the persistence of absorption through a great range of temperature. The light which passed through the liquid oxygen had a light blue colour resembling that of the sky.

Of not less interest are the experiments of Knut Augstrom, which show that the carbonic acid and aqueous vapour of the

atmosphere reveal their presence by dark bands in the invisible infra-red region, at the positions of bands of emission of these

It is now some thirty years since the spectroscope gave us for the first time certain knowledge of the nature of the heavenly bodies, and revealed the fundamental fact that terrestrial matter

ia not peculiar to the solar system, but is common to all the stars which are visible to us.

which are visible to us.

In the case of a sar arch as Capella, which has a spectrum
almost identical with that of the sun, we feel justified in concluding that the matter of which is is beaut up is sumilar, and
that its temperature is also high, and not very different from the
becomes, however, one of very great difficulty when we have to
do with spectra differing from the solar type. We are thrown
hack upon the laboratory for the information necessary to enable
us to interpret the indications of the spectroscope as to the
chemical nature, but dentally and pressure, and the temperature of the celestial masses.

What the spectroscope immediately reveals to us are the waves which were set up in the other filling all interstellar space, years or hundreds of years ago, by the motions of the molecules of the celestial substances. As a rule, it is only when a body is gaseous and sufficiently bot that the motions within its molecules can produce bright lines and a corresponding shorption. The spectra of the heavenly bodies are, molecul, to a great extent absorption appears, but we have usually to study them through the corresponding emission spectra of hother brought of the corresponding emission spectra of hother brought of all selections of all selections are considered as the contraction of all selections are considered as the contraction of all selections are considered as the contraction of the corresponding contractions are considered as the contraction of all selections are considered as the contraction of the corresponding contractions are considered as the contraction of the contract years or hundreds of years ago, by the motions of the molecules mto the gaseous form and rendered luminous by means of names or of electric discharges. In both cases, unfortunately, as has been shown recently by Profs. Livening and Dewar, Wullner, E. Wiedemann, and others, there appears to be no certain direct relation between the luminous radiation as shown in the spectroscope and the temperature of the flame, or of the gaseous scope and the temperature of the flame, or of the gaseous contents of the weature table—that is, in the usual sense of the term as applied to the mean motion of all the molecules. In the content of the content of the content is the content to the charge is taking place may be low, as shown by a thermometer, quite apart from the consideration of the extreme smallness of the mass of gas, but the vibrations of the luminous inolecules must be violent in whatever way we suppose them to be set up by the discharge, if we take Schuster's view that comparatively few molecules are carrying the discharge, and that it is to the fierce encounters of these alone that the luminosity is due, then if all the molecules had similar motions, the temperature of the gas would be very high.

gas would be very night.

So in flames where chemical changes are in progress, the vibratory motions of the molecules which are luminous may be, in connection with the energy set free in these changes, very different from those corresponding to the mean temperature of the flame.

Under the ordinary conditions of terrestrial experiments, erefore, the temperature or the mean we were of the molecules may have no direct relation to the total radiation, which, on the other hand, is the sum of the radiation due to each luminous

molecule These phenomena have recently heen discussed by Ebert from

the standpoint of the electro-magnetic theory of light
Very great caution is therefore called for when we attempt to reason by the aid of laboratory experiments to the temperature eavenly bodies from their radiation, especially on the reasonable assumption that in them the luminosity is not ordinarily associated with chemical changes or with electrical dis-charges, but is due to a simple glowing from the ultimate con version into molecular motion of the gravitational energy of shrinkage.

shrinkage.

In a recent paper Stas maintains that electric spectra are to be regarded as distinct from flame spectra, and from researches of his own, that the pairs of lines of the sodium spectrum other than D are produced only by disruptive electric distinctions. tram other than D are produced only by disruptive electric dis-charges. As these pairs of lines are found revensed in the solar spectrum, he concludes that the sun's radiation is due mainly to electric discharges. But Wolf and Diacon, and later, Watts, observed the other pairs of lines of the sodium spectrum when the vapour was raised above the ordinary temperature of the Bunsen fisme. Recently, Liveling and Dewar saw easily, be source, name necessity. Avering and Dewar saw easily, be sided D, the citron and green pairs, and sometimes the blue pair and the orange pair, when hydrogen charged with sodium vapour was burning at different pressures in oxyge... In the case of sodium vapour, therefore, and presumably in all other vapour, and gases, at it is a matter of indifference whether the necessary

vibratory motion of the molecules is produced by electric dis-charges or by flames. The presence of lines in the solar spec-rum which we can only produce electrically, is an indication, however, as Stas points out, of the high temperature of the

We must not forget that the light from the heavenly bodies may consist of the combined radiations of different layers of gas at different temperatures, and possibly be further complicated to an unknown extent by the absorption of cooler portions of gas

Not less caution is needed if we endeavour to argue from the Not less castion is needed if we endeavour to argue from the condening of insen and the coming in of a continuous spectrum as no the relative presser of the gas in the coleculal atmospheres, the widening of the lines in a Plucker's tible follows upon in-creasing the density of the residue of hydrogen in the tube, when the whatening ser more frequently disturbed by fresh encounters, and that a broadening of the softium lines in a finne at ordinary pressure as produced by an increase of the quantity of softium in the flame, but it is doubtful if pressure, as distinguished from quantity, does produce an increase of the breadth of the lines. An individual molecule of sodium will be tensibly in the same Ån Individual molecule of sedium will be tenshly in the same condition, considering the relatively enforment number of the copiously fed with the volume sair. With a small quantity of sodium wapour the intensity will be feetle except near the maximum of the lines; which, however, the quantity is increased, allow the light from the sidditional molecules met with in the path of the vasual ray to strengthen the reduction of the mole-cules farther back, and so mercease the breadth of the lines

In a gaseous mixture it is found, as a rule, that at the same ressure or temperature, as the encounters with similar molecules become fewer, the spectral lines will be affected as if the body were observed under conditions of reduced quantity or tem-

In their recent investigation of the spectroscopic behaviour of flames under various pressures up to forty atmospheres, Profs Live-ing and Dewar have come to the conclusion that, though the prominent feature of the light emitted by flames at high press appears to be a strong continuous spectrum, there is not the slightest indication that this continuous spectrum is produced by On the contrary, photometric observations of the brightness of On the contrary, photometric observations of the brightness of the continuous spectrum, as the pressure is varied, show that it is mainly produced by the mutual action of the molecules of a gas. Experiments on the sodium spectrum were carried up to a pressure of forty atmospheres without producing any definite effect on the world of the lines which could be ascribed to the pressure. In a similar way the lines of the spectrum of water showed no signs of expansion up to twelve atmospheres ; though more intense than at ordinary pressure, they remained marrow and clearly defined

It follows, therefore, that a continuous spectrum cannot be considered, when taken alone, as a sure indication of matter in the liquid or the solid state. Not only, as in the experiments the injust or the soils state wood only, as in the experiments already mentioned, such a spectrum may be due to gas when under pressure, but, as Maxwell pointed out, if the thickness of a medium, such as sodium vapour, which radiates and absorbs different kinds of light, be very great, and the temperature ligh, the light emitted will be of exactly the same composition as that tions which are feehly emitted will be also feehly absorbed, and can reach the surface from immense depths. Schuster has shown

can rach the surface from mmense depths. Schuster has shown that oxyges, even in a partially exhausted tube, can give a con-tinuous spectrum when excited by a feeble electric duchauge, trum; but, on the subtrainty leaves a spectrum does not neces-sarily above the presence of compounds—that it, of molecules to the subtrainty of the subtrainty leaves that support on the containing different kinds of atoma-but simply of a more com-plex molecule, which may be made up of similar atoms, and the case—for examine, in the diffuse bands of the absoration seentherefore, an allotropic condution of the same body. In some cases—for example, in the diffuse bands of the absorption spec-trum of oxygen—the hands may have an intensity proportional to the square of the density of the proportional to the square of the density of the part of the square of the case of pressure, or it may be to the constraint to which the one-localist are subject during their encounter with one another. It may be thought that at least in the coincidences of highly lines we are not the solid ground of certainty, since the broght of

the waves set up in the ether by a molecule, say of hydrogen, is the most fixed and absolutely permanent quantity in nature, and is so of physical necessity, for with any alteration the mole-

374

and is so of physical necessity, for with any siteration to mou-cule would cease to be hydrogen coincidence were certain; but Such would be the case if the confidence were certain; but an absolute coincidence can be only a matter of greater or less probability, depending on the resolving power employed, on the number of it hims which correspond, and on their characters. number of the lines which correspond, and on their characters. When the coincidences are very numerous, as in the case of iron and the solar spectrum, or the lines are characteristically grouped, as in the case of hydrogen and the solar spectrum, we may regard the coincidence as certain; but the progress of science has been greatly retarded by resting important conclusions. science has been greatly retarded by resting important conclusions upon the apparent connedence of single lines, in spectroscopes of very small resolving power. In such cases, unless other reasons supporting the connedence are present, the probability of a real coincidence is allost too small to be of any ability of a real consodence is al- out too small to be of any importance, especially in the case of a heavenly body which may lave a motion of approach or of recession of unknown amount. But even here we are met by the confinemon introduced by multiple special, corresponding to different molecular groupings, and the confinemon introduced by multiple special, corresponding to different molecular groupings are considered to the confinement of the

I have said as much as time will permit, and I think indeed sufficient, to show that it is only by the laborious and slow pro cess of most cautious observation that the foundations of the science of celestial physics can be surely laid. We are at present in a time of transition, when the earlier, and, in the nat sent in a time of transition, when the earlier, and, in the nature of things, less precise, observations are giving place to work of an order of accuracy much greater than was formerly considered attainable with objects of such small brightness as the stars.

The accuracy of the earlier determinations of the spectra of

The accuracy of the earlier determinations of the spectra of the terrestrial elements are in most case; inswifcient for modern work on the stars as well as on the sun. They fall much below the reale adopted in Rowland's map of the sun, as well as below the degree of accuracy attained at Potsdam by photography in a part of the spectrum for the brighter stars increase of resolving power very frequently breaks up into groups, in the spectra of the vun and stars, the lines which had been regarded as single, and their supposed coincidences with terrestrial lines fall to the ground. For this reason many of the early conclusions, to the ground. For this reason many of the early concussions, based on observation as good as it was possible to make at the time with the less powerful spectroscopes then in use, may not be found to be maintained under the much greater resolving power of modern instruments

The spectroscope has failed as yet to interpret for us the remarkable spectrum of the Aurora Borealis. Undoubtedly in this phenomenon portions of our atmosphere are lighted up by this phenomenon portions of our atmosphere are figured up by electric discharges we should expect, therefore, to recognize the spectra of the gases known to be present in it. As yet we As yet we the spectra of the gates known to be present in it. As yet we have not been able to obtain smilar spectra from these gases artificially, and especially we do not know the origin of the principal line in the green, which often appears alone, and may have, therefore, an origin independent of that of the other lines. Recently the suggestion has been made that the aurora is a phe-nomenon produced by the dust of meteors and falling stars, and that near positions of certain auroral lines or flutings of man-ganese, lead, barium, thallium, iron, &c , are sufficient to justify games, each garding meteoric dust in the atmosphere as the origin of the auroral spectrum. Liveing and Dewar have made a con-clusive research on this point, by availing themselves of the dust of excessive minuteness thrown off from the surface of electrodes of various metals and meteorites by a disruptive dis-charge, and carried forward into the tube of observation by a more or less rapid current of air or other gas. These experiments more of less rapio current on air or other gas. These experiments prove that metallic dust, however fine, suspended in a gas will not act like gaveous matter in becoming luminous with its characteristic spectrum in an electric dicharge similar to that of the aurora. Prof. Schuster has suggested that the principal the aurora. Prof. Schauter has suggested that the principal line may be due to some very light gas which is present in soo small a proportion to be detected by chemical analysis or even by the spectroscope in the presence of the other gases near the earth, but which at the belight of the auroral discharges is in a sufficiently greater refative proportio; to give a spectrum. Lemstrom, indeed, states that he saw this line in the silent day

charge of a Holtz machine on a mountain in Lapland. The lines may not have been obtained in our laboratories from the atmo-spheric gases on account of the difficulty of reproducing in tabes with sufficient nearness the conditions under which the auroral

discharges take place.

In the spectra of comets the spectroscope has shown the In the spectra of comets the spectroscope has shown the presence of carbon presumably in combination with hydrogen, and also sometimes with nitrogen; and in the case of comets approaching very near the sun, the lines of sodium, and other lines which have been supposed to belong to iron. Though the researches of Prof. II. A. Newton and of Prof. Schuparelli of the prof. II. A. Newton and of Prof. Schuparelli of the prof. II. A. Newton and of Prof. Schuparelli or the prof. II. A. Newton and of Prof. Schuparelli or the prof. II. A. Newton and of Prof. Schuparelli or the prof. II. A. Newton and or the prof. leave no doubt of the close connection of comets with correleave no doubt of the close connection of comets with corre-sponding periodic meteor swarms, and therefore of the probable identity of cometary matter with that of meteorites, with which the spectroscopic evidence agrees, it would be perhaps unwise at present to attempt to define too precuely the exact condition of the matter which forms the nucleus of the comet. In any case the part of the light of the comet which is not reflected solar the part of the light of the counter which is not reflected solar light can excretely be attributed to a high temperature produced by the clashing of separate meteoric stones set up within the nucleus by the sum's disturbing force. We must look rather to disruptive electric discharges, produced probably by processes of evaporation due to increased solar heat, which would be amply sufficient to set free portions of the occluded gases into the vacuum of space. May it be that these duckarges are assuated, sulhcient to set free portions of the ofcolineting master into the accounted passes. May it be that these dischanges are sunsteed, or the utility of the substitution of the unit has been designed and the utility of the unit has been then the substitution of the sun's light? Lenard and Wolfe have shown that ultim-volet light can produce a discharge from a negatively electrified protect of metal, while Hallwachs and Righl have shown further that utility utility land light when a constant protect of the sun's light and the substitution of the supported matter when a const approaches the sun, and help to explain an electrified condition of the exposured matter which would have to return to that point in speaking of the salar corona. A very great advance has been made in our knowledge of the constitution of the sun by the recent work at the Johns Hopkins ultraversity by means of photography and concave graining, in ultraversity by means of photography and concave graining, in directly with the appears of the terreptial excellent power. Growland has shown that the lines of thirty-ax, terrestrial

Rowland has shown that the lines of thirty-six terrestrial Rowland has shown that the lines of thirty-ix terretiral clements at lest-1 are certainly present in the solar spectrum, while eight others are doubtful. Fifteen elements, including intogen as it shows titelf under an electric discharge in a vacuum tube, have not been found in the solar spectrum Some ten other elements, inclusive of oxygeen, have not yet been

Some ten other elements, inclusive of oxygen, have not yet been compared with the sun's spectrum.

Rowland remarks that of the fifteen elements named as not found in the sun, many are so classed because they have few strong lines, or none at all, in the limit of the solar spectrum as The lines of hismuth are compound and to diffuse. Therefore even in the case of these fificen elements there is little evidence

that they are really absent from the sun.

It follows that if the whole earth were heated to the temperature of the sun, its spectrum would resemble very closely the

ture of the sun, its -pectrum would resemble very closely the old a spectrum of the sun the terrestrial elements in the sun

the terrestrial elements in the sun. Best results of eleven years of Siss in a recent paper gives the in a state of party, and on the possibility of decomposing them by the physical and chemical forces at our disposal. His experiments on calcium, strontum, lithium, magnesium, silver, sodium, and thallium, show that these substances reatm their individuality under all conditions, and are unalterable by any forces that we can bring to bear upon

Prof. Rowland looks to the solar lines which are unaccounted for as a means of enabling him to discover such new terrestrial elements as still lurk in rare minerals and earths, by confronting their spectra directly with that of the sun. He has already resolved yttrium spectroscopically into three components, and

actually into two. The comparison of the results of this indeactually into two. The comparison of the results of this inde-pendent analytical method with the renarkable but different conclusions to which M. Lecoq de Boisbaudran and Mr. Crookes have been led respectively, from spectroscopic observation of these bodies when glowing under molecular bombardment in a vacuum tube, will be awaited with much interest. It is worthy remain tune, will be awaited with much interest. It is worthy of remark that, as our knowledge of the spectrum of hydrogen in its complete form came to us from the stars, it is now from the san that chemistry is probably about to be enriched by the dis-

covery of new elements. In a discussion in the Bakerian Lecture for 1885 of what we knew up to that time of the sun's corona, I was led to the conclusion that the corona is essentially a phenomenon similar in the cause of its formation to the tails of comets-namely, that it the cause of its formation to the tails of comets—namely, that it consists for the most part probably of matter going from the sen under the action of a force, possibly electrical, which vance as the surface, and can therefore in the case of highly attenuated matter easily master the force of gravity even near the san Though many of the coronal particles may return to the sun, those which form the long rays or streamer do not return; they separate and soon become too diffused to be any longer variety. and may well go to furnish the matter of the zodiacal light, which and may well go to turnish the matter of the zontacal light, which otherwise has not received a satisfactory explanation. And further, if such a force exist at the sun, the changes of terrestrial magnetism may be due to direct electric action, as the earth moves through lines of inductive force.

These conclusions appear to be in accordance broadly with the lines along which thought has been directed by the results of subsequent eclipses. Prof. Schuster takes an essentially similar view, and suggests that there may be a direct electric connection between the sun and the planets. He asks further whether the between the sun and the planets. He asks further whether the sun may not act like a magnet in consequence of its revolution about its axis. Prof Bigelow has recently treated the coronal forms by the theory of spherical harmonics, on the supposition that we see phenomena similar to those of free electricity, the rays being lines of force, and the coronal matter discharged from rays being lines of force, and the coronal matter dascharged from the tan, or at least arranged or controlled by these forces. At power may be lost, and gravitation set in, bringing the matter lost to the sun. The mitter which does lever the sun sper-naturely transported to the equatorial plane of the corona, in attack the sun attention of the coronal plane of the coronal in the sun spering the sun attention of the sun sper-naturely transported to the equatorial plane of the coronal. In tancer from the sun along this equator of such like material Photographs on a larger scale will be destrable for the full development of the conclusions which may follow from the natively of the curved forms of the coronal structure. Prof Schaeberle, of the curvest form of the coronal structure. Froi Scinaevite however, considers that the coronal phenomena may be satisfactorily accounted for on the supposition that the corona is formed of streams of matter ejected mainly from the spot zones with great initial velocities, but smaller than 33z miles per second Puriber that the different types of the corona are due to the effects of perspective on the streams from the earth's place at the time relatively to the plane of the solar equator

Of the physical and the chemical nature of the coronal matter we know very little. Schuster concludes, from an examination of the eclipses of 1882, 1883, and 1886, that the continuous spectrum of the corona has the maximum of actinic intensity displaced considerably towards the red when compared with the spectrum of the sun, which shows that it can only be due in spectrum of the sun, which shows that it can only be due in small part to solar light scattered by small particles. The lines of calcium and of hydrogen do not appear to form part of the normal spectrum of the corona. The green coronal line has no known représentative in terrestrial sub-tances, nor has Schuster been able to recognize any of our elements in the other lines of the corons.

The spectra of the stars are almost infinitely diversified, yet they can be arranged with some exceptions in a series in which the adjacent spectra, especially in the photographic region, are scarcely distinguishable, passing from the bluish-white stars like Sirius, through stars more or less solar in character, to stars with banded spectra, which divide themselves into two apparently independent groups, according as the stronger edge of the bands is towards the red or the blue. In such an arrangement the

sun's place is towards the middle of the series.

At present a difference of opinion exists as to the direction in the series in which evolution is proceeding, whether by further condensation white stars pass into the orange and red stages, or whether these more coloured stars are younger and will become white by increasing age. The latter view was suggested by white by mcreasing age. Johnstone Stoney in 1867

NO. 1138, VOL. 44]

About ten years ago Ritter in a series of papers discussed the behaviour of gaseous masses during condensation, and the probable resulting constitution of the heavenly bodies. Accordprobable resulting constitution of the heavenly bodies. According to him, a size passes through the orange and red stages are proposed to the proposed of the constitution of the proposed stage, and a second time during a more prolonged stage of gradual cooling. He suggested that the two groups of bandes stars may correspond the proposed stage of gradual cooling. He suggested that the two groups of bandes stars may correspond the stage of the s

Recently a similar evolutional order has been suggested, which is based upon the hypothesis that the nebulæ and stars consist of colliding meteorie stones in different stages of condensation. of colliding meteorie stones in different stages of condensation. More recently the view has been put forward that the diversified spectra of the stars do not represent the stages of an evolutional progress, but are due for the most part to differences of original constitution.

The few minntess which can be given to this part of the address are insufficient for a discussion of these different views I purpose, therefore, to state briefly, and with reserve, as the I purpose, therefore, to state briefly, and with reserve, as the subject is obscure, some of the considerations from the characters as the consideration from the characters are considerated by the consideration of the consideration of the stars from their photographic spectrum in 1879. In Sorder is essentially the same as Vogel had previously proposed in his classification of the stars as Vogel had previously proposed in his classification of the stars as Vogel had previously proposed in his classification of the stars in 1874, in which the white stars, which are most numerous, represent the early adult and most persistent stage of stellar life, the solar condition that of full maturity and of commencing age; while in the orange and red stars with banded spectra we see the while in the orange and red stars with bandes spectra we see the setting in and advance of old age. But this statement must be taken broadly, and not as asserting that all stars, however different in mass and possibly to some small extent in original constitution, exhibit one invariable succession of spectra.

In the spectra of the white stars the dark metallic lines are relatively inconspicuous, and occasionally absent, at the same time that the dark lines of hydrogen are usually strong, and more or less broad, upon a continuous spectrum, which is remarkable for its brilliancy at the blue end. In some of these stars the hydrogen and some other lines are bright, and sometimes variable

As the greater or less prominence of the hydrogen lines, dark or bright, is characteristic of the white stars as a class, and diminishes gradually with the incoming and increase in strength of the other lines, we are probably justified in regarding it as due to some conditions which occur naturally during the pro-gress of stellar life, and not to a pecuharity of original consti-

To produce a strong absorption spectrum a substance must be at the particular temperature at which it is notably absorptive; and, further, this temperature must be sufficiently below that of the region behind from which the light comes for the gas to the region behind from which the light comes for the gas to spear, so for as in special rays are concerned, as darkness upon spear, so for as in special rays are concerned, as darkness upon be raised before it can also wit is characteritic emission and short feelbieness or absence of the other lines, not to the passety of the feelbieness or absence of the other lines, not to the passety of the substances behind them as to show rebelly, if all all, by reversion Such a state of things would more probably be found, it seems to me, in conduction attentor to the solar size. A considerable eooling of the sun would probably give rise to banded spectra due to compounds, or to more complex molecules, which might form near the condensing points of the vapours

form near the condensing points of travelor as consisting of glow-ing vapours surrounded by a photosphere where condensation is taking place, the temperature of the photospheric layer from which the greater part of the radiation comes being constantly renewed from the hotter matter within.

At the surface the convection currents would be strong, pro-dueing a considerable commotion, by which the different gases would be mixed and not allowed to retain the inequality of proportions at different levels due to their vapour densities

Now the conditions of the radiating photosphere and those of the gases above it, on which the character of the spectrum of a the gases above it, on which the character of the spectrum of a star dependar, will be determined, not alone by temperature, but also by the force of gravity in these regions; this force will be fixed by the star's mass and its stage of condensation, and will become greater as the star continues to condense.

In the case of the sun the force of gravity has already become In the case of the sun the force of gravity has already become or great at the surface that the decrease of the density of the gaves must be extremely rapid, passing in the space of a few miles from atmosphere pressure to a density infaintesimally small; consequently the temperature gradient at the surface, if determined solely by expansion, must be extremely rapid. The gases here, however, are exposed to the fierce radiation of the if any solid or liquid particles were present from condensation or

convection currents. convection currents.

From these causes, within a very small extent of space at the surface of the sun, all bodies with which we are acquainted should fall to a condition in which the extremely tenuous gas could no longer give a visible spectrum. The insignificance of snound tail to a constituen in which the extremely tensious gas could no longer give a visible spectrum. The insignificance of the single subtended by this spice as seen from the earth should cause the boundary of the solar atmosphere to appear defined. If the boundary which we see he that of the sun proper, the matter above it will have to be regarded as in an essentially dynamical condition—an assemblage, so to speak, of gaseous pro-jectiles for the most pair failing back upon the sun after a greater or less range of flight. But in any case it is within a space of relatively small extent in the sun, and probably in the other solar stars, that the reversion which is manifested by dark

lines is to be regarded as taking place
Passing backward in the star's life, we should find a gradual weakening of gravity at the surface, a reduction of the tempera ture gradient so far as it was determined by expansion, and con-vection currents of less violence producing less interference with he proportional quantities of gases due to their vapour densities. while the effects of cuptions would be more extensive

while the effects of captions would be more extensive At last we might come to a state of things in which, if the star were hot enough, only hydrogen might be sufficiently cool relatively to the mistianto behind to produce a strong absorption. The lower vapours would be protected, and might continue to be relatively to the scholer, their hotse might be possible as be relatively to the scholer, their lines might be possible as continuous spectrum, besides, their lines might be possible as the scholer before the configurations scheric unthe vapours themselves of a continuous spectrum

In such a star the light radiated towards the upper part of the atmosphere may have come from portions lower down of the atmosphere many have come from portions lower down of the atmosphere itself, or at least from parts not greatly hotter. There may be no such great difference of temperature of the low and less low portions of the star's atmosphere as to make the darkening effect of absorption of the protocted metallic vapours. to prevail over the illuminating effect of their emission,

It is only by a vibratory motion corresponding to a very high temperature that the bright lines of the first spectrum of hydro temperature that the bright lines of the first spectrum of hydro-gen can be brought out, and by the equivalence of absorbing and emitting power that the corresponding spectrum of absorption should be produced, yet for a strong mbsorption to show it-olf, the hydrogen must be cool relatively to the source of redulation behind it, whether this be condensed particles or gas. Saeli conditions, it seems to me, should occur in the earlier rather than in the more advanced singer of condensation.

The subject is obscure, and we may go wrong in our mode of conceiving of the probable progress of events, but there can be no doubt that in one remarkable instance the white-star spectrum is associated with an early stage of condensation.

Sirius is one of the most conspicuous examples of one type of this class of stars Photometric ob cryations combined with its ascertained parallax show that this star emits from forty to sixty times the light of our sun, even to the eye, which is insensible to ultra-violet light, in which Sirius is very rich, while we learn from the motion of its companion that its mass is not much from the motion of its companion that its mass is not much more than double that of our sun. It follows that, unless we attribute to this star an improbably great emissive power, it must be of immense sue, and in a much more diffuse and there-fore an earlier condition than o it sun; though probably at in later stage than those white stars in which the hydrogen lines are bright.

A direct determination of the relative temperature of the photospheres of the stars might possibly be obtained in some cases from the relative position of maximum radiation of their cases not the error position in maximum a standard or the continuous spectra. Langley has shown that through the whole range of temperatures mobile we can experiment, and presume ably at temperatures beyond, the maximum of radiation-power has solid bodies gradually shifts upwards in the spectrum from the infra-red through the red and orange, and that in the sun it has reached the blue.

The defined character, as a rule, of the stellar lines of absorp-

NO. 1138, VOL. 44]

tion suggests that the vapours producing them do not at the tion suggests that the vapour producing them do not at the tome time excet any strong power of general absorption. Con-sequently, we should probably not go far wrong, when the pho-tosphere consusts of luquid or solid particles, if we could compare select parts of the continuous spectrum between the stronger lines, or where they are fewers. It is obvious that, if extended portions of different stellar spectra were compared, their true

relation would be obscured by the line-absorption. relation would be obscured by the line-absorption.

The increase of imperiator, as shown by the rise in the pectrum of the maximum of radiation, may not always be accompanied by no corresponding greater brightness of a star as estimated by the eye, which is an extremely imperfect photometric astrument. Not only a time eye blind to large regions of radiation, but even for the small image of light that we can use the contract of the contract of the contract of the contract of radiation, but even for the small image of light that we can use the contract of the contract of radiation, but even for the small range of light that we can use the contract of the contract see the visual effect varies enormously with its colour. According to Prof. Langley, the same amount of energy which just caables us to perceive light in the crimion at A would in the green produce a visual effect 100,000 times greater. In the violet the proportional effect would be 1600, in the blue 50,000, in the yellow 30,000, in the orange 14,000, and in the ref 1200. in the yellow 25,000, in the orange 14,007, and in the real ratio. Captain Abney's recent experiments make the sensitiveness of the eye for the green near F to he 750 times greater than for the red about C It is for this reason, at least in part, that I suggested in 1864, and have since shown by direct observation, that the

in 1804, and have since shown by direct observation, that the spectrum of the nebula in Andromeda, and presumably of similar nebular, is in appearance, only weather the the second of the specific properties of would increase in visual brightness, but not in proportion to the increase of energy radiated by it

The brightness of a star would be affected by the nature of the substance by which the light was chiefly emitted. In the laboratory, solid carbon exhibits the highest emissive power A laboratory, solic caroon exhibits the nignest emissive power stellar stage in which radiation comes, to a large extent, from a photosphere of the solid particles of this substance, would be favourable for great brilliancy. Though the stars are built up of matter essentially similar to that of the sun, it does not follow that the proportion of the different elements is everywhere the same. It may be that the substances condensed in the photospheres of different stars may differ in their emissive powers, but

probably not to a great extent

All-the heavenly hodies are seen by us through the tinted medium of our atmosphere. According to Langley, the solst stage of stars is not really yellow, but, even as gauged by our imperfect eye, would appear blush-white if we could free our-selves from the deceptive influences of our surroundings. From these considerations it follows that we can scarcely

infer the evolutional stages of the stars from a simple comparison mer en erviucional stages of mestan from a simple comparison of their eye magnitudes. We should expect the white stars to be, as a class, less dense than the stars in the solar stage. As great mass imply bring in the solar type of spectram at a relatively earlier time, some of the brightest of these stars may be very massive, and builder than the sum-for example, the bril very measure, and brighter that the sun—for example, the brilliant star Arcturus. For these reasons the solar stars should not only be dense than the white stars, but perhaps, as a class, surpass them in mans and eye-brightness. It has been shown by Lane that, so long as a condensing gaseous mass remains subject to the laws of a purely gaseous.

body, its temperature will continue to rise

he greater or less breadth of the lines of absorption of hydrogen in the white stars may be due to variations of the

hydrogen in the white stars may be due to variations of the depth of the hydrogen in the inter-of sight, armang from the case throughout the control of the case throughout the case through the case throughout throughout the case throughout the case throughout the ca anto which they have been davided by Vogel, Scheiner has re-cently investigated minor differences as suggested by the charac-cently investigated minor differences as suggested by the charac-too, that so far as his observations go the white stars in the constitution of from stand done, with the exception of Algoi, as passessing dark ince in the blue which has appearently the superior of the contract of the superior of the spectra of the spectra of these stars dark lines corresponding to the principal lines of the beright-line stars, and the planetary neutics with the

exception of the chief nebular line. The association of whatestaw with nebular matter in Orion, in the Pickides, in the region of the Milky Way, and in other parts of the heavest, may be regarded as falling in with the view that I have taken. In the stars possibly further reasoned from the with exception in the stars possibly further reasoned from the withen class than the stars of the stars, which are distinguished by absorption bands with their stronger edge towards the blue, the hydrogen lines are narrower than in the solar spectrum. In these stars, the density-gradient is more probably still more rapid, the depth of hydrogen may be less, the star of the stars of encounters with dissuminar mole state. In you have not a star with dark hydrocarbon bands, the hydrogen lanes have not been certainly observed; if they are really absent, it may be because the temperature has fallen below the point at which hydrogen can essert its characteristic absorption, besides, some the hydrocarbon bands may indicate a later evolutional stage, but the electric are.

the electric arc.

A number of small stars more or less similar to those which are known by the names of their discoverers, Wolf and Rayet, are known by the names of their discoverers, Wolf and Rayet, have been found by Pickering in his photographs. These are remarkable for several brillast groups of bright lines, including special properties of the properties of th nebula, the bright groups being due to the gaseous matter out side the star. Mr. Robeits, however, has not been able to bring out any indication of nebulosity by prolonged exposure. The remarkable star n Argis may belong to this class of the beavenly bodies.

In the nebules, the elder Herschel saw portions of the first must or "thanning fluid" out of which the heaven and the earth had been slowly fashioned. For a time this view of the nebules gave place to that which regarded them as external galaxies, comment "sand heaps," too remote to be resolved into separate sizes; though mided, in 1883, Mr. Herbert Speacer showed that the observations of nebulæ up to that time were really in favour

the observations of nebular up to that tune were really in favour of an evolutional progress
In 1864, I brought the spectroscope to bear upon them, the bright times which thanked upon the eyes showed the source of the bright times which thanked upon the eyes showed the source of the tap thanked the source, as an early stage of sidereal life at the probably their true place, as an early stage of sidereal life. At that early time our knowledge of sidelar spectra was small For this reason partly, and probably also under the undue under the undue under the control of the stage of the sta no longer have to an whina special modification or our own type of sun, but find ourselves in presence of objects possessing a distinct and peculiar plan of structure." Two years later, however, in a lecture before the Association, I took a truer position "Our views of the universe," I said, "are undergoing

ton "Our views of the universe," I said, "are undergoing important changes, let us wast for more facts, with minds unfettered by any dogmatic theory, and therefore free to receive the teaching, whatever it may be, of new observations." Let us turn saide for a moment from the nebulis in the sky to the conclusions to which philosophers had been resultily led the conclusions to which philosophers had been resultily led to the conclusions of which philosophers had been resultily led to the conclusions of which will be the conclusions of the co aggregation of bodies, but a system resting upon a multitude of relations pointing to a common physical cause. From these considerations Kant and Laplace formulated the nebular hypothesis, resting it on gravitation alone, for at that time the science of the conservation of energy was practically unknown. These of the conservation of case in the supposition that the space now occupied by the solar system was once filled by a vaporus mass, the formation of the sun and planets could be reasonably ac counted for

By a totally different method of reasoning, modern science by a totally dimercial mention of reasoning modern science traces the solar system backward step by step to a similar state of things at the beginning. According to Helmboltz, the sun'a heat is maintained by the contraction of his mass, at the rate of about 220 feet a year. Whether at the present time the sun is getting hotter or colder we do not certainly know. We can reason back to the time when the sun was sufficiently expanded reason back to the time when the san was subnemity expanded to fill the whole space occupied by the volar system, and was reduced to a great glowing nebula. Though man's life, the life of the rose perhaps, it so short to give us direct evidence of any distinct stagges of so august a process, still the probability is great that the nebular hypothesis, especially in the more precise form given to it by Koche, does represent broadly, notwithstanding some difficulties, the succession of events through which the

ing some united that is a sun and planets have passed

The nebular hypothesis of Laplace requires a rotating mass of fluid which at successive epochs became unstable from excess of motion, and left behind rings, or more probably perhaps lumps, of matter from the equatorial regions.

The difficulties to which I have referred have suggested to some thinkers a different view of things, according to which it is not necessary to suppose that one part of the system gravita-tionally supports another. The whole may consist of a congeries of discrete bodies even if these bodies be the ultimate molecules of matter. The planets may have been formed by the gradual of the condensing solar system consisted of separate particles or or masses, we have no longer the fluid pressure which is an essential part of Laplace's theory. Faye, in his theory of evolution fro is meteorites, has to throw over this fundamental idea of the nebular hypothesis, and he formulates instead a different succession of events, in which the outer planets were formed last, a theory which has difficulties of its own

Prof George Darwin has recently shown, from an investigaon certain assumptions a meteoric swarm might behave as a coarsegas, and in this way bring back the fluid pressure exercised by one part of the system on the other, which is required by Laplace's theory One chief assumption consists in supposing Laplace's theory One chief assumption consists in supposing that such inelastic bodies as meteoric stones might attain the effective elasticity of a high order which is necessary to the theory through the sudden volatilization of a part of their mass at an encounter, by which what is virtually a violent explosive is introduced between the two colliding stones Prof Darwin is careful to point out that it must necessarily be obscure as to how a small mass of solid matter can take up a very large amount of energy in a small fraction of a second

energy in a small fraction of a second.
Any direct indications from the heavens themselves, however, slight, are of so great value, that I should perhaps in this consistence of the control of all retirementable photograph, by Mr. Roberts, of the great is beabla in Andromedia. On this plate we seem to have presented to us some stage of contained evolution on a gigantic scale. The photograph shows a sort of white pool disturbance of the luminous matter which is distributed in a plane inclined to the line of sight, in which a series of rings of bright inclined to the line of vigit, in which a series of rings of bright matter exparated by dark spaces, greatly foreinbortened by per-manent of the parallex of this nebula, but there can be little uponant of the parallex of this nebula, but there can be little cloubt that we are looking upon a system very remote, and libera-fure of a magnitude great beyond our power of adequate com-prehencing. The matter of this nebula, in whatever state it may be, appears to be distributed, as in so many other nebulæ. in rings or spiral streams, and to suggest a stage in a succession of evolutional events not inconsistent with that which the nebular procliness requires. To likes this object more directly to any particular stage in the formation of particular stage in the formation of particular stage in the formation of the compare thing; great with small," and might be indeed to introduce a false analogy; but, on the other hand, we should err through an excess of ceution if we did not accept the remarks be features brooght to light by this photograph as a presumptive indication of a progress of events in cosmical history following broadly upon the fines of Lappiese's theory.

The old were of the original matter of the reluin, that it consisted of a "fire" mist, "".

"a tumultuous cloud Instinct with fire and aitre."

fell at once with the rise of the science of thermodynamics. fell at once with the rase of the science of thermodynamics. In 1654, Helinholts showed that the supportion of an original fiery condition of the neshboard stuff was unnecessary, stace in the potential energy sufficient to generate the high temperature of the sun and stars. We can scarcely go wrong in attributing the high of this neshboard control of the gravitational energy of shrankage into molecular motion. The side, that the light of comets and of nebulae may be due

to a succession of Ignited flashes of gas from the encounters of meteoric stones was suggested by Prof. Tait, and was brought to the notice of this Association in 1871 by Sir William Thomson

the notice of this Association in 1871 by Sir William Thomson in his Presidential Address.

The spectrum of the bright-line nebulæ is certainly not such a spectrum as we should expect from the flashing by collisions of meteorities similar to those which have been analyzed in our meteorities smillar to those which have been analyzed in our laboratories. The strongest inse of the substances which in the case of such meteorities would first show themselves, fron, sodium, mageneum, micele, &c., are not those which distinguish the nebalar spectrum. On the contrary, this spectrum is chiefly remarkable for a few brilliant innex, very narrow and defined, upon a lackground of a faint continuous spectrum, which contains namerous bright lines, and probably some lines of contains namerous bright lines, and probably some lines of absorption.

assopption.

The two most conspicuous lines have not been interpreted; for though the second line falls near, it is not consedied with a strong double line of iron. It is hardly necessary to say that though the near position of the bughet cloudle line of inforger, as seen in a small spectroscope in 1864, naturally suggested at that early time the possibility of the presence of this element in the nebula, I have been careful to point

sence of this element in the nebulz, I have been careful to point out, to preven imasprehension, that in more recent years the introgen lines and subsequently a lead line have been employed. The third line we know to be the excoold line of the first appearum of hydrogen. In Keeler has seen the first hydrogen line in the red, and photographs show that this hydrogen spectrum of substitution of the white first appearance of the hydrogen line first l

We are not surprised to find associated with it the line D₃, near the position of the absent sodium lines, probably due to the atom of some unknown gas, which in the sun can only show

near the position of the absent sociam lines, probably due to the intelligination of the absent social lines are intelliginated in the continuity of highest temperature, and for that reason does not reveal tutelf by absorption in the solar spectrum. It is not unreasonable to assume that the two brightest lines, which are of the same order, are produced by substances of a similar nature, in which a vibratory motion corresponding to a similar analysis, in which a vibratory motion corresponding to a few unknown elements which are wanting in our terrestral chemistry between hydrogen and lithium, unless indeed $D_{\rm h}$ to the lightest aid of hydrogen. The contract of the contract

small number of luminous molecules or atoms would probably be sufficient to make the nebulic as bright as they appear to us. On such an assumption the average temperature may ic low, but the individual particles, which by their encounters are luminous, must have motions corresponding to a very high temperature. and in this sense be extremely hot

In such diffuse masses, from the great mean length of free path, the encounters would be are but correspondingly violent, and tend to bring about vibrations of comparatively short period, as appears to be the case if we may judge by the great relative brightness of the more refrangible lines of the nebular

spectrum. Such a view may perhaps reconcile the high temperature which Such a view may pernapa reconcile the high temperature which the nebular spectrum undoubtedly suggrests with the much lower mean temperature of the gaseous mass, which we should expect at so early a stage of condensation, unless we assume a very enormous mass; or that the matter coming together had previously considerable motion, or considerable molecular agitation.

The inquisitiveness of the human mind does not allow us to

remain content with the interpretation of the present state of the cosmical masses, but suggests the question-

"What see'st thou else In the dark backward and abyon of time"

What was the original state of things? how has it come about that by the side of ngeing worlds we have nebulæ in a relatively jounger stage? Have any of them received their birth from dark suns, which have collided into new life, and so belong to a second or later generation of the heavenly bodles?

During the short historic period, indeed, there is no record of

such an event; still it would seem to be only through the collision of dark suns, of which the number must be increasing, that a temporary rejuvenescence of the heavens is possible, and by such abblings and flowings of stellar life that the inevitable end to which evolution in its apparently uncompensated progress is carrying us can, even for a little, be delayed

We cannot refuse to admit as possible such an origin for

nebula

nebulæ
In considering, however, the formation of the existing nebulæ
we must bear in mind that, in the part of the heavens within
our ken, the stars still in the early and middle stages of evolution
exceed greatly in number those which appear to be in an
advanced condition of condensation. Indeed, we find some stars which may be regarded as not far advanced beyond the nebular condition

It may be that the cosmical bodies which are still nebulous owe their later development to some conditions of the part of owe their later development to some conditions of the past of pasce where they occur, such as, concribably, a greater original homogeneity, in consequence of which concleasation began itself the past of the pas connected with it.

connected with it.
If light matter be suggested by the spectrum of these nebular, it may be asked further, as a pure speciation, whether in them we are wintening possibly a later condensation of the light representation of the light present proportion, after the first growth of worlds into which he heaver matter condensed, though not without some entanglement of the lighter substances. The write extent and great diffusiones of the highly the nebularly over a large part of the constitution of Orno may be regarded perhaps as pointing in this direction. The diffuse orbitons matter streaming round the rais direction — The diruse neonious matter streaming round the Pleiades may possibly be another instance, though the character of its spectrum has not yet been accertained.

In the planetary nebulæ, as a rule, there is a sensible increase

of the faint continuous spectrum, as well as a slight thickening of the bright lines towards the centre of the nebula, appearances which are in favour of the view that these bodies are condensing

Prof G Darwin, in his investigation of the equilibrium of a rotating mass of fluid, found, in accordance with the independent researches of Poincaré, that when a portion of the central body becomes detached through increasing angular velocity, the portion should bear a far larger ratio to the remainder than is observed in the planets and satellites of the solar system, even thus the compact had been a compact and satellites of the solar system, even taking into account heterogeneity from the condensation of the parent mass

parent mass

Now this state of things, in which the masses though not equal are of the same order, does seem to prevail in many enables, and to have given borth to a large class of lineary stars. Mr. See has recently investigated the evolution of bodies of this man, and the same continuous of the same continuous stars. The same continuous parent me to the relatively large mass-ration of the component bodies, as well as in the high econtricities of their orbits brought shout by tidal fraction, which would play a more important part in the evolution of such systems. Considering the large number of these bodies, he suggests that the solar system should perhaps no longer be regarded as representing cettalli evolution in its normal form—

A goodly Paterne to whose perfect mould He fashioned them

but rather as modified by conditions which are exceptional.

It may well be that in the very early stages condensing masses are subject to very different conditions, and that condensation may not always begin at one or two centres, but sometimes set in at a large number of points, and proceed in the different cases along very different lines of evolution

Besides its more direct use in the chemical analysis of the heavenly bodies, the spectroscope has given to us a great and unexpected power of advance along the lines of the older astronomy. In the future, a higher value may, indeed, be placed upon this indirect use of the spectroscope than upon its chemical rescletions

By no direct astronomical methods could motions of approach or of recession of the stars be even detected, much less could they be measured. A body coming directly towards us or going directly from us appears to stand still. In the case of the stars we can receive no assistance from change of size or of brightness The stars show no true disks in our instruments, and the nearest of them is so far off that if it were approaching us at the rate of a hundred miles in a second of time, a whole century of such rapid approach would not do more than increase its brightness by the one-fortieth part.

by the one-fortisth part. Still it was only too clear that, so long as we were mable to Still it was only too clear that, so long as we were mable to Still it was only too clear that the still it was one too the solid that the liter of sight, the speed and direction of the solid that the still it was too the solid that the still it was to the solid that the still it was to the still it was to solid the has wen, must remain more or less imperfedly prower, which, though so essential, appered almost the nature of things to lie for ever beyond our grasp; it enables us measure directly, and under favorable currountanest to within a mile per second, or even less, the speed of approach or of recession of a heavenly body. This method of observation has recession of a heavenly body. This method of observation has the great advantage for the astronomer of being independent of the distance of the moving body, and is therefore a applicable and as certain in the case of a body on the extreme confines of the visible universe, so long as it is bright enough, as in the case

the visible universe, to long as it is origin enough, so in increase of a neighbouring planet.

Doppler had suggested as far back as 1841 that the same principle, on which he had shown that a sound should become sharper or flatter if there were an approach or a recession between the car and the source of the sound, would apply equally to light; and he went on to say that the difference of colour of some of the binary stars might be produced in this way by their motions. Doppler was right in that the principle is true in the case of light, but he was wrong in the particular conclusion which he drew from it. Even if we suppose a star conclusion which he drew from it. to be moving with a sufficiently enormous velocity to after sensibly its colour to the eye, no such change would actually be seen, for the reason that the store of invisible light beyond both mits of the visible spectrum, the blue and the red, would be drawn upon, and light waves invisible to us would be exalted or degraded so as to take the place of those raised or lowered in the visible region, and the colour of the star would remain unchanged. About eight years later Fireau pointed out the importance of considering the individual wave lengths of which importance of considering the individual wave tengths of which white light is composed. As soon, however, as we had learned to recognize the lines of known substances in the spectra of the heavenly bodies, Doppler's principle became applicable as the bass of a new and most fruitful method of investigation. This measurement of the small shift of the celestial lines from their measurement of the small shift of the celestial lines from their measurement of the small shift of the celestral lines from their rule positions, as shown by the same lines in the spectrum of a terrestrial substance, gives to us the means of ascertaining directly in miles per account the speed of approach or of recasion of the heavenly body from which the light has come Anaecount of the first application of this method of research to the stars, which was made in my observatory in 1865, and the start of the start, which was made in my observatory in 1865, and the start of the start of

given by Sit Usarret Stokes from tails chair at the meeting at Lexter in 1859. The stellar motions determined by me were shortly after confirmed by Prof. Vogel in the case of Sirus, and in the case of other stars by Mr. Christie, now Astronomer Royal, at Greenwich, but, necessarily, in consequence of the madequacy of the instruments then in use for so delicate an inquiry, the amounts of these motions were but approximate.

The method was shortly afterwards taken np systematically at Greenwich and at the Rugby Observatory. It is to be greatly regretted that, for some reasons, the results bave not been sufficiently accordant and accurate for a research of such exceptional ciently accordant and accurate for a research of such exceptional delicacy. On this account probably, as well as that the spectro-scope at that early time had scarcely become a familiar ustrument in the observatory, astronomers were allow in availing themselves of this new and remarkable power of investigation. That this comparative neglect of so truly wonderful a method of ascortaining what was other wise outside our powers of observaascertaming what was otherwise outside our powers or observa-tion has greatly retarded the progress of astronomy during the last fifteen years, is but too clearly shown by the brilliant result-which within the last couple of years have followed fast upon the recent masterly application of this method by photography

at Production, and by see with the readel accuracy at the Left Departure. As the last this used to be sectioned to the last the place as one of the most potent methods of astronomical research. It gives as the motions of approach and of recession, not in angular measures, which depend for their translation into not in an agree which depend for their translation into the last translation and the last translation of the l

to look for the more important discoveries in sidereal astronomy which will be made during the coming century.

In his recent application of photography to this method of determining celestial motions, Prof. Vogel, assisted by Dr. Scheiner, considering the importance of obtaining the spectrum
of as many stars as possible on an extended scale without an exposure inconveniently long, wisely determined to limit the part of the spectrum on the plate to the region for which the ordinary silver-bromide gelatine plates are most sensitive—namely, to a small distance on each side of G—and to employ as namely, to a small datance on each sale of G—and to employ as the line of comparison the hydrogen line near C, and recently also certain lines of iron. The most ninute and complete mechanical arrangements were provided for the purpose of securing the absolute rigidity of the comparison spectrum rela-tively to that of the star, and for permitting temperature adjustments and other necessary ones to be made.

The perfection of these spectra is shown by the large number of lines, no fewer than 250 in the case of Capella, within the small region of the spectrum on the plate Already the motions of about fifty stars have been measured with an accuracy, in the case of the larger number of them, of about an English mile per second

At the Lick Observatory it has been shown that observations can be made directly by eye with an accuracy equally great.

Mr. Keeler's brilliant success has followed in great measure from the use of the third and fourth spectra of a greating 14.438 lines The marvellous accuracy attainable in his hands to the mch on a suitable star is shown by observations on lince nights of the star Arcturus, the largest divergence of his measures being not greater than six tenths of a mile per second, while the mean of the three nights' work agreed with the nican of five photographic determinations of the same star at Potslam to within one-tenth of an highsh mile. These are determinations of the motions of a sin so stupendoesly remote that even the method of parallax practically fails to findnen the depth of intervening space, and by mile that the same star of the same star determinations of the same star at Potsdam to within one-tenth

line of signt of lowne values passes, and considerable motion in space, if the values respected that nebulae considerable motion in space, if the best elider motions must have belonged to the nebule out of which they have been revolved. We may be the special passes when the special passes were specially materially in the semination of the motions greater than twenty five miles per second, were unsufficient. Mr. Keller has found in the examination of tensificated, which receives the special passes which were the

nebula, of vast extent and of extreme tenuty, is probably more nearly at rest relatively to the stars of our system than any other celestial object we know, still it would seem more likely that cerestian object we know, still it would seem more likely that even here we have some motion, small though it may be, than that the motions of the matter of which it is formed were so absolutely balanced as to leave this nebula in the unique position of absolute immobility in the unique of whirling and drifting sums and systems of suns.

and systems of suns.
The apperiors but of of determining criestal motions 1.
The apperiors in could be been failed in a wew but not allogather understeen detection, for it has, so to speak, given in a separating power far beyond that of any televoop the glass maker and the optician could construct, and so enabled us to support the could be supported by the could be supported by the support of the support of

of stellar systems, in which the components are in some eases of nearly equal magnitude, and in close proximity, and are re-volving with velocities greatly exceeding the planetary valocities

volving with verocines grown, of our system.

The K line in the photographs of Mizar, taken at the Harvard College Observatory, was found to be double at intervals of College Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory, was found to be double at intervals of the college Observatory. fifty-two days. The spectrum was therefore not due to a single source or ught, but to the combined effect of two stars moving periodically in opposite directions in the line of sight, It is obvious that if two stars recolve round their common centre of gravity in a plane not perpendicular to the line of sight, all the lines in a starting common centre. source of light, but to the combined effect of two stars moving lines in a spectrum common to the two stars will appear alternately single or double.

In the case of Mizar and the other stars to be mentioned, the spectroscopic observations are not as yet extended enough to furnish more than an approximate determination of the element-

of their orbits

Mizar especially, on account of its relatively long period-about 105 days-needs further observations. The two stars are moving each with a velocity of about fifty miles a second, probably in elliptical orbits, and are about 143 millions of miles apart. The stars, of about equal hightness, have together a

apart. Inc stars, or about equal transfer and mass about forty times as great as that of our sun.

A similar doubling of the lines showed itself in the Harvard. A similar doloring of the inica showed user in the same re-photographs of \(\theta\) Aurige at the remarkably close interval of almost exactly two days, indicating a period of revolution of about four days. According to Vogel's later observations, each star has a velocity of nearly seventy miles a second, the distance between the stars being little more than seven and a half mil-lions of miles, and the mass of the system 4'7 times that of the sun. The system is approaching us at the speed of allout sixteen

The telescope could never have revealed to us double stars of this order. In the case of \$\beta\$ Auriga, combining Vogel's distance with Pritchard's recent determination of the star's parallax, the greatest angular separation of the stars as seen from the earth greatest angular separation of the stars as seen from the earth would be 1/200 part of a second of ace, and therefore very fire too small for the highest powers of the largest telescopes. If we take the relation of aperture to separating power usually accepted, an object glass of about 80 feet in dismeter would be needed to restolve this binary star. The spectroscope, which takes no note of distance, magnifies, so to speak, this minute angular separation 4000 times, in other words, the doubling of the spectrum of the second seco the lines, which is the phenomenon that we have to observe, amounts to the easily measurable quantity of twenty seconds of

There were known, indeed, variable stars of short period,

There were known, indeed, variable stars of short period, which it had been uggested might be explained on the hypothesis of a dark body recolving about a bright sen in a few days, but his theory was net by the objection that no such systems of the contraction of the star of the contraction of the

length star as it moved in its orbit alternately lowards and from our system, which would need for its detection the fiducial positions of terrestinal lines compared directly with them. For such observations the Potsdam spectrograph was well adapted. Prof. Vogel found that the highly star of Algol did adapted. Prof. Vogel found that the highly star of Algol did pulsate backwards and forwards in the visual direction in a period corresponding to the known variation of its light. The explanation which had been suggested for the star's variability, that it was partially eclipsed at regular intervals of 68 8 hours by a dark companion large enough to cut of nearly five sixths of its light, was therefore the true one. The dark companion, no longer able to hide uself by its obscureness, was brought out into the light of direct observation by means of its grayitational

Seventeen hours before minimum, Algol is receding at the rate of about 24½ miles a second, while seventeen hours after minimum it is found to be approaching with a peed of about 25½ miles. From these data, together with those of the varia-tion of vis light, Vogel found, on the assumption that both staffs have the same density, that the companion, nearly as large

as the sun, but with about one-fourth his mass, revolves with a velocity of about infly-te miles a second mile of the desired of of or second miles as the second miles of the complex of

that they are in different stages of coordensation, and unsatimating the stage of coordensation, and obscure companion as inclined to the line of sight, the companion will peak above or helow the bright star, and produce no variation of its light. Such systems may be numerous in the heavens. In Voget's photographs, Spica, which is not variable, by a small shifting of its lines reveals a backward and forward periodical. shifting of its lines reveals a backward and forward periodical pulsation due to orbital motion. As the pair whirl round their common centre of gravity, the bright star is sometimes ad-vancing, at others receding. They revolve in about four days, each star moving with a velocity of about fifty-ix miles a second in an orbit probably nearly circular, and possess a combined
mass of rather more than two and a half times that of the sun.

mass of rather more than two and a half times that of the sun. Taking the nous probable value for the star's parallax, the greatest angular separation of the star would be far too small to the star between the star that the star type, while the bright star is solar in character, the composite spectrum would be solar with the hydrogen libes unusually strong. Such a spectrum would miself afford some probability of a double orange, and suggest the existence of a composition of the star type, and suggest the existence of a composition of the star type of the star t

In the case of a true binary star the orbital motions of the air would reveal themselves in a small periodical swaying of

the hydrogen lines relatively to the solar ones.

Prof. Pickering considers that his photographs show ten stars Prob. Pickering considers that his photographs show the stars with composite spectra; of these, five are known to be double. The others are ~ Perset, f Aurige, 8 Sagittani, 31 Ceti, and 8 Capricorni. Perhaps \$ 1. yrc: should be added to this list. In his recent classical work on the rotation of the sun, Duncr.

has not only determined the solar rotation for the equator but for different parallels of latitude up to 75° The close accord ance of his results shows that these observations are sufficiently accurate to be discussed with the variation of the solar rotation for different latitudes which had been determined by the older astronomical methods from the observations of the solar spots.

Though I have already spoken incidentally of the invaluable and which is furnathed by photography in some of the applications of the apertoms of the apertoms of the apertoms of the apertom of the approximation of the approximati to this subject

to this subject.

The longraphy is no new discovery, lessing about half—century.

Photography is no new discovery, lessing about half—century processes and the processes are presented in about 10 miles and the spitch control of the spitch of the spitch to the spitch bodies dates from the memorable occasion when, in 1830, Arago, announcing Dageners, spoke of the possibility of taking pictures of the sun and moon by the new process, yet that it is only within a few parts that the spitch and the spitch is the spitch in the process of the sun and moon by the new process, yet that it is only within a few parts that the spitch advanced in autonomical methods and dis-

years that notable advances in autonomical methods and dis-covery have been mided by its and.

The explanation is to be found in the comparative manifolding.

The explanation is to be found in the comparative manifolding that the property of the propert

grained texture, meets the needs of the assistance. In our possesses extreme sensitiveness; it is always ready for use;

it can be placed in any position; it can be exposed for hours, lastly, it does not need immediate development, and for this reason can be exposed again to the same object on succeeding reason can be exposed again to the same objection succeeding nights, so as to make up by several instalments, as the weather may permit, the total time of exposure which is deemed

Without the assistance of photography, however greatly the resources of genius might overcome the optical and mechanical difficulties of constructing large telescopes, the astronomer would have to depend in the last resource upon his eye. Now we canhave to depend in the list resource upon his eye. Now we can-not by the force of continued looking hring into view an object of vision. But the feeblest light which falls upon the plate is not lost, but is taken in and stored up continuously. Each hour the plate gathers up 3600 times the light-energy which it received during the fair second. It is by this power of accumulation that curring the first second 11 is by this power of accumulation that the photographic plate may be said to increase, almost without limit, though not in separating power, the optical means at the disposal of the astronomer for the discovery or the observation of faint objects

of faint objects.

Two principal directions may be pointed out in which[photography is of great service to the astronomer. It enables him within the comparatively short time of a single exposure to secure permanently with great exactness the relative positions of hundreds or even of thousands of stars, or the minute features of numercus or even of thousands of stars, or the minute features of nebular or other objects, or the phenomena of a passing eclipse, a task which by means of the eye and hand could only be ac-complished, if done at all, after a very great expenditure of time and labour. Photography bats in the power of the attronomer complished, if done at all, after a very great expenditure of time and labour. Photography plats it in the power of the astronomer to accomplish in the short span of his own life, and so enter into their fruition, great works which otherwise must have been passed on by him as a heritage of labour to succeeding genera-

The second great service which photography renders is not simply an aid to the powers the astronomer already possesses. On the contrary, the plate, by recording light-waves which are both too small and too large to excite vision in the eye, brings him into a new region of knowledge, such as the infra-red and

nim into a new region of knowledge, such as the intra-red and the ultra-violet parts of the spectrum, which must have remained for ever unknown but for artificial help The present year will be memorable in astronomical history for the practical beginning of the Photographic Chait and Catalogue of the Heavens, which took their origin in an International Conference which met in Paris in 1887, by the invitation of M l'Amiral Mouchez, Director of the Paris Observatory

The richness in stars down to the ninth magnitude of the photographs of the comet of 1882 taken at the Cape Observatory photographs of the come to fi88s taken at the Cape Observatory under the superintendence of Dr Gill, and the remarkable star charts of the Brothers Henry which followed two years later, stomatics the astromatical was found. The great excellence of the star o Observatory has conducted the initial steps, through the many delicate and difficult questions which have unavoidably presented themselves in an undertaking which depends upon the harmonious working in common of many nationalities, and of no fewer than eighteen observatories in all parts of the world so lewer than eignteen onservatories in all parts of the world. The three years since 1887 have not been too long for the de-tailed organization of this work, which has called for several elaborate preliminary investigations on special point in which our knowledge was insufficient, and which have been ably earlied out by Profs Vogel and Bakhayara, Dr. Trepted, Dr. Scheiner, Dr. Gill, the Astronomer Koyal, and others: Time also was required for the construction of the new and special sow asser equired for the construction of the new and special. instruments.

instruments. The decisions of the Conference in their final form provide for the construction of a great photographic chart of the heavest with exposures corresponding to forly uninted: exposure at some construction of a great photographic chart of the heavest construction of the conference of the construction of the conference of the construction of the construction of the positions of the starts a release with lines at distances of 5 mm apartrius to be previously impressed by a faint light upon the plate, so that the

image of the rheats will appear together with the images of the stars when the plate is developed. This great work will be durised, according to their listuides, among eighteen observations proyided with aimitar instruments, though not necessarily con-structed by the same maker. Those in the Bruish dominious and at Tacubusy have been constructed by Srt Howard Grubb.

Besides the plates to form the great chart, a second set of plates for a catalogue is to be taken, with a shorter exposite, which will give stars to the eleventh magnitude only. These plates, by a recent decision of the Permanent Committee, are to be pushed on as actively as possible, though as far as may be practicable plates for the chart are to be taken concurrently. Photographing the plates for the catalogue is but the first step in this work, and only supplies the data for the claborate measurements which have to be made, which are, however, less laborious than would be required for a similar catalogue without the sid of photography.

Already Dr Gill has nearly brought to conclusion, with the

assistance of Prof Kaptevn, a preliminary photographic survey

of the southern heavens

of the southern heavers With an exporter sufficiently long for the fantiest stars to impress themselves upon the plate, the accoundating action still help the plate of the pl the affirmative, though at present the empirical formula which have been suggested for this purpose differ from each other Captain Abney proposes to measure the total photographic action, including density as well as size, by the obstruction which the stellar image offers to light.

A further question follows as to the relation which the photoaphic magnitudes of stars hear to those determined by eye graphic magnitudes of star's hear to those determined by eye Visual magnitudes are the physiological expression of the eye's integration of that part of the star's light which extends from the red to the blue. Photographic magnitudes represent the plate's integration of another part of the star's light—namely, from a little below where the power of the eye leaves off in the blue to where the light is cut off by the glass, or is greatly reduced by want of proper corrections when a refracting telescope is used. It is obvious that the two records are taken by different methods It is obvious that the two records are taken by district measures in dissipalar units of different parts of the star's light. In the case of certain coloured stars the photographic brightness is very different from the visual brightness; but in all stars, changes, different from the visual brightness; but in all stars, clianges, especially of a temporary character, may occur in the photographic or the visual region, unaccompanied by a similar change in the other part of the spectrum. For these reasons it would seem desirable that the two sets of magnitudes should be tabulated. lated independently, and be regarded as supplementary of each

The determination of the distances of the fixed stars from the The determination of the distances of the fixen same proofs in small apparent shift of their positions when viewed frost widely separated positions of the earth in its orbit is one of the most refuned operations of the observatory. The great precision with which this minute angular quantity—a fraction of a second only has to be measured, is so delicate an operation with the ordinary micrometer, though, indeed, it was with this instrument that the classical observations of Sir Robert Ball were made, that a special instrument, in which the measures are made by moving the two halves of a divided object-glass, known as a heliometer, has been pressed into this service, and quite recently, in the skilful hands of Dr. Gill and Dr. Elkin, has largely increased our knowledge in this direction.

It is obvious that photography might he here of great service, if we could rely upon measurements of photographs of the same stars taken at suitable intervals of time Prof. Pritchard, same same taken at suitable intervals of time. Fro, Frichard, to whom is due the honour of having opened this new path, asked by his assistants, has proved by elaborate investigations that measures for parallat may be safely made upon photographic plates, with, of course, the advantage of learner and repetition; and he has already by an assistant continuous control of the properties of t parallax for twenty-one stars with an accuracy not inferior to that of values previously obtained by purely astronomical

methods.

The regarkable successes of astronomical photography, which depend upon the plate's power of accumulation of a very feeble light esting continuously through an expoure of several hours, are worthy to be regarded as a new revelation. The first chapter

opened when, in 1880, Dr. Henry Draper obtained a picties of the netwis of Orion; but a more important advance was made in 1883, when Dr. Common, by his photographs, brought to our knowledge details and extensions of this nebula hisherto unknown. A further disclosure took place in 1885, when the submound of the common of the nebula hisherto unknown. A further disclosure took place in 1885, when the part of the property of the ened when, in 1880, Dr. Henry Draper obtained a picture great extension of the nebular region which surrounds the traper-rum in the constillation of Orion. By his photographs of the great nebula in Andromeda he has shown the true significance of the dark canals which had been seen by the eye. They are in reality spaces between successive rings of bright matter, which appeared nearly straight towing to the micration in which they lie relatively to us. There bright rings surround an unde-fined central luminous mass. I have a fready apoken of this

processing.

Some recent photographs by Mr. Russell show that the great rift in the Milky Way in Argus, which to the eye is rout of status, is in rentity uniformly covered with them. Also, quite recently, Mr. George Hale has photographed the prominences by means of a grating, making use of the lines H and K.

The heavens are richly but very irregularly inwrought with stars, the brighter stars cluster into well known groups upon a background formed of an enlacement of streams and convoluted windings and intertwined spirals of fainter stars, which becomes

SECTION A

MATHEMATICS AND PHYSICS.

OPENING ADDRESS BY PROF OLIVER J. LODGE, D.Sc., LL D., F.R S., PRESIDENT OF THE SECTION

DURING the past year three or four events call for special mention in an annual deliverance of this kind by a physicist. One is the Faraday centenary, which was kept in a happy and One is the rarady centenary, which was kept in a happy and simple manner by a cosinopolitan gaihering in the place so long associated with his work, and by discourses calling attention to the modern development of discoveries made by him Another is the decease of the veteran Wilhelm Weber, one of

the originators of that absolute system of measurement which, though still ungrasped in its simplicity and completeness by the though still suggested in testing the support and comprehension by the majority of men engaged in practice, nor even, I fear, wholly understood by some of those engaged in University teaching, has yet done so much, and is destined to do (still more, for the unification of physical science, and for a thorough comprehension of its range and its limitations.

neation of physical science, and for a thorough comprehension.

A third event of importance during the year is the discovery in America of a binary system of stars, revolving round each other with grotscept hast, and with a promitty to each other such as to render their ordinary opical separation quite largost the stars of the property of the singular abstractly of the notion which was once property the singular abstractly of the notion which was once propounded by a philosopher, that motion of stars in our line of sight must for ever remain unknown to se; when the mere time for ever remain unknown to se; when the mere time of revolution of a stelline, compared with its distance from its mation on that head. As a matter of pedagogy it is mation on that head. As a matter of pedagogy it is mation on that head. As a matter of pedagogy it which is generally known to apply to the periodic disturbances concerned to the property of the principle called Doppler's which is generally known to apply to the periodic disturbances concerned to the property of the principle called the property of the

principle ¹ Any discrepancy between the observed and the calculated times of revolution of stars round each other can possibly
be explained by a relative motion between us and the pair of
bodies along the line of sight,

the first committee conditions asserting that the apparent
time of revolution of a satellite of Justice depends on the distance of the earth from that planet, instead of on the speed I
should indeed be sorry to be judged by the performance of my
on students, but I few that many of the less obvious mistakes
made by reasonably trained examination candidates are more
directly irrecable to their teachers than some of us as teachers would like to admit.

The change in the refrangibility of light by reason of the motion of its source, though commonplace enough now, was at first regarded as too su all to be observed, and one or two attempts directed to detecting the effect of this principle on the specira of the stars, or sometimes on sunlight reflected by a 45° mirror into the line of the earth's motion (which is not a possible method), wholly failed 1 take pleasure in remembering that this effect was clearly observed for the first time by the gentleman we this year honour as our President, and that it is by this very means that the latest sensational discovery in astronomy of the rapidly revolving twin star & Autigut, by Prof Picker-ing and the staff connected with the Draper Mcmorral, was made

The funds for the investigation that led to this result were and if & Aurigo does not constitute a satisfactory memorial, I am at a loss to conceive the kind of tombstone which the relations of a man of science would prefer

The fourth event to which it behoves me to refer is the practical The fourth event to which it believes the discovery of a physical method for colour photography. When I say practical I do not mean commercial, nor do I know that it I say practical I do not mean commercian, no do a most supplicable to the ordinary business of the photographer Whether it does or not, it is a sound achievephotographer Whether it does or not, it is a sound achieve-ment by physical means of a result which the chemical means ment by physical means of a result which the chemical means hitherto tred failed, some think necessarily failed, to produce I asy practical, because already it had been suggested as possible theoretically; and a step toward it, indeed very near it, had been actually made The first suggestion of the method, so far as I know, as made by Lord Rayleigh in the course of a matheniancial paper on the reflection of light, and with reference to some results of Beenjured obtained on a totally different plan. He said in a note that if by normal reflection waves of light were converted into stationary waves, they could shake out silver in siraia half a wave length apart, and that such strata would give selective reflection and show iridescence.

The colour of certain crystals of chlorate of potash, described in a precise manner by Sir George Stokes (Proc Roy Soc., February 1885), and also the colours of opal and ancient glass, returns 1989), and no the colours of opat and ancient glass, and been elaborately and completely explained by Lord Rayleigh ou this theory of a periodic structure (the laminated structure in the case of chlorate of potash being caused by twinning) (Fh.I.) Mag., September 1888, pp. 256 and 241), and he subsequently illustrated it with sound and a series of mushin disks one behind the ratest it with sounds and a series of musin disks one behind the other on as eto I say-tongs. Each membrane reflected an inappreciable amount, but successive equitistant membranes reinforced each other's action, and the entire set reflected distinctly one definite note, of wave-length twice the distance between adjacent muslim. So also with any series of equalistant strata each very slightly reflecting. They should give selective reflection, and the spectrum of their reflected beam should show a single line or narrow band, corresponding to a wave length twice the distance of the strata apart.

twee the distance of the strain apart.*

1) P. Huggma has polymlos ofto one a spriferly clear statement to the strain of the str

Independently of all this, Herr Otto Wiener, imitsting Hertz's experimenta with ordinary light, in 1889 reflected a beam directly back on itself, and, by interposing a very thin collodion film at extraordinarily oblique incidence, succeeded in the difficult experiment of so magnifying by the cosine of inclination the half wave length, as to get the silver deposited in strata of visible width, and thus to photograph the interference nodes themselves at the places where they were cut by the plane of the film (Wiedemann's Annalen, vol xl , 1890)

Then M. Lippmann, using a thicker film, not put obliquely but normal to the light, obtained the strata within the thickness of the film stself—hundreds of tayers, and so, employing incidence light of definite wave-length, was able to produce a stratified deposit, which reflected back at appropriate incidences the same wave-length as produced it , thus reproducing, of course, the definite colour

It is probable that the silver is first shaken out at the ventral segments, but that the strain so formed are thick and blurry. segments, but that the sirans so formed are thick and blurry. I competure that by over expourer this deposit is nearly all mopped up again, traces being left only at the noises, where the action is very feelbe and takes a long time to occur. but that these resultainstrain, heing fairly sharp and definite, will be likely to give much better-fletcs. And so I suppose that these are what are actually effective in obtaining M. Lippinian's very interesting, though not yet practically useful, results.

I now leave the retrospect of what has been done, although many other topics mucht usefully detain us, and I proceed to glance forward at the progress shead and at the means we have

giance forward at the progress anead and at the means we have for effectively grappling with our due share of it. There is a subject which has long been in my mind, and which I determined to bring forward whenever I had a cathedral opportunity of doing so, and now, if ever, is a sintable occasion It is to call attention to the fact that the further progress of physical science in the somewhat haphazard and amateur fashion in which it has been hitherto pursued in this country is becoming increasingly difficult, and that the quantitative portion especially increasingly difficult, and that the quantitative portion especially should be undertaken in a permanent and publicly supported physical laboratory on a large scale. If such an establishment were to weaken the sinews of private enterprise and individual research it should be strenously opposed; hut, in my opinion, it would have the opposite effect, by relieving the private worker of much which he can only with great difficulty, sacrifice, and expense, undertake. To illustrate more precisely what I mean, expense, undertake. To illustrate more precu The amateur asit is sufficient to recall the case of astronomy. The amateur as-tronomer has much work lying ready to the hand, and heg graphes with it manfully. To him is left the striking out of new lines and the guerila warfare of science. Skirmishing and brilliant carely) evolutions are his battural field, he should not be called upon to take part in the general infantry advance. It is wasting energies, and he could not do it in the long run well. Wi energies, and he could not do it in the long run well. What, for instance, would have been the state of astronometry—the nautical almanac department of astronomy—without the consecutive and systematic work of the National Observatory at Greenwish? It may be that some enthusiastic amateurs would have devoted their lives to this routine kind of work, and here at one time and there at another a series of accurate observations would live been kept for several years. Pur ued in that way, however, not only would the effort be spaamodic and temporary, nowever, not only would the effort be spaamodic and temporary, but the energy and enthusians of those amateurs would have been diverted from the pioneering more suited to them, and have heen cramped in the groove of routine, emineatly adapted to a permanent official staff, but not wholesome for an individual

Long continued consecutive observations may be made by a leader of science, as functions may be tabulated by an eminent mathematician, but if the work can be done almost equally well (some would say better) by a professional observer or com-

putator, how great an economy results

parties, and we great take compily to subpute. The ohm has been determined with a figure, perhaps with 5 figure, accuracy, thinks of the list of emment men to whose severe personal laborative ow this result, and ask if the spoil is worth the cost. Perhaps in this case it st, as a speemen of a well conducted determination. We must have a few speemens, and our leaders determination. We must have a few specimens, and our leaders must show as the way to do things. But let us not continue to use them for such purposes much longer. The quest of the fifth or sath declimal is a very legiturate, and may secome a very absorbug, quest, but there are plenty of the rank and file who can undertake it if properly generalled and led not as soluted individuals, but as workers in a National Laboratory under a competent head and a governing committee. By this means work far greater in quantity, and in the long run more exact in quality, can be turned out, by patient and conscientions thoour without much genus, by the gradual improvement of instrumental means, by the skill acquired by practice, and by the steady drudgery of routine. Paris has long had one form of such an institution, in the Conservatore de Afris et Métlers, and has been able to imthe Conservators east Arts et occuers, and nas need no see to impose the metric system on the civilined would in consequence, the first of just such a system. Berlin is now starting a similar or a more ambituous scheme for a permanent national physical institute. Is it not time that England, who in physical selence, I wenture to think, may in some sort claim a leading place,

I venture to think, may in some sort claim a reasing piace, should be thinking of starting the same movement?

The Meteorological and Magnetic Observatory at Kew (in the nauguration of which this Association took so large a part) is a step, and much useful quantitative work is done there. The new Relectine Standardising Laboratory of the Board of Trade is another and, in some respects perhaps, a still closer appproxi-mation to the kind of thing I advocate But what I want to see is a much larger establishment erected on the most suitable site. limited by no speciality of aim nor by the demands of the commer cial world, furnished with all appropriate appliances to be amended and added to as time goes on and experience grows, and invested with all the dignity and permanence of a national institution a with all the dignity and permanence of a national institution a Physical Observatory, in fact, percessly comparable to the Green-with the review of the control of the co in electrical matters already attained. The work and appliances of the mechanical engineer eclipse the present achievements of the physicist in point of accuracy, and it is by the aid of the mechanical and opticisal that precision even in astronomy has reached so high a stage. There is no reason why physical determinations should be conducted in an amateur fashion, it the committee of the property of the proper paratively imperfect instruments, as at pre-ent they mortly are Discoveries lie along the path of extreme accuracy, and they will turn up in the most unexpected way

The aberration of light would not have been discovered had not Bradley heen able to measure to less than 1 part in 10,000, and what a brilliant and momentous discovery it was! He was aiming at the detection of stellar parallax, but the finite velocity of light was a bigger discovery than any parallax This is the type of result which sometimes lurks in the fifth decimal, and which confers upon it an importance beside which the demands of nich who wish to serve the tasto and the pocket of the British public sink into insignificance
In a National Observatory accuracy should be the one great

end: the utmost accuracy in every determination that is decided end: the utmost accuracy in every determination that is decided on and made. Only one thing should be more thought of than the fifth againscant figure, and that is the sixth. The con-sequences flowing from the results may safely be left; such as are not obvious at once will distil themselves out in time. And are not obvious at once will distil themselves out in time. And the great army of outside physicists, assured of the good work being done at headquarters, will (to speak again is astronomical parable) cease from peddling with taking transits or altitudes, and will be free to discover comets, to invent the spectroscope, to watch solar phenomena, to chemically analyse the stars, to devise celestial photography, and to elaborate still more celestial theories, all of which novelties in their maturity may be handed over to the National Observatory, to be henceforth incorporated with, and made part of, its routine life; leaving the advance guard and skirmishers free to explore fresh territory, poracte with, and made part of, its routine life; leaving the an-vance guard and skirnishers free to explore fresh territory, secure in the knowledge that what they have acquired will be properly surveyed, mapped, and utilised, without further atten-tion from them. At to the practical applications, they shay any case he left to take care of themselves. The institute of humanity in this direction, and the so called solid gains associated with practical achievements, will always secure a sufficient number of acute and energetic workers to turn the new territory number of acute and energetic workers to turn the new territory mot arable land and pasture displeted to the demands of the most acute land and pasture displeted to the demands of the fettile is, of course, heyond pritter; but it is not the work of the ponner. As Mr. Husky eloquently put it, when contrasting the application of science with the advanced of the supplementation of the suppl craftsmen. But even while the cries of jubilation resound, and this flotsam and jetsam of the tide of investigation is being turned into the wages of workmen and the wealth of capitalists. the crest of the wave of scientific investigation is far away on its course over the illimitable ocean of the unknown."

I have spoken of the work of the National Laboratory i devoted to accuracy. It is hardly necessary to say that it will be also the natural custodian of our standards, in a state fit for use and for comparison with copies sent to be certified. Else perhaps some day our standard ohm may be buried in a brick wall at Westminster, and no one living may be able to recall precisely where it is,

But, in addition to these main functions, there is another. equally important with them, to which I must briefly refer.
There are many experiments which cannot possibly be conducted Inere are many experiments which cannot possibly be conducted by an individual, because forty or fifty years is not long enough for them. Secular experiments on the properties of materials— the elasticity of metals, for instance, the effect of time on mole-cular arrangement; it is influence of long exposure to light, or to

heat, or to mechanical vibration, or to other physical agents

Does the permeability of soft fron decay with age, by reason
of the gradual cessation of its Amperian currents? Do gases of the gradual cessation of its Ampirana currents? Do guess cool themselves when adiabalically preserved, by reaso on immediate when adiabalically preserved, by reaso on immediate the season of the

a national laboratory, with permanent traditions and a con-tinuous life, is undoubtedly the only appropriate place. At such a place as Glasgow the exceptional magnitude of a present occupant may indeed inspire sufficient piety in a successor to secure the continuance of what has been there begun, but in secure the continuance or what has been there began, and in most college laboratories, under conditions of migration, in-terregnum, and a new rigime, continuity of investigation is hopeless.

I have at any rate said enough to indicate the kind of work

for which the establishment of a well-furnished laboratory with fully equipped staff is desirable, and I do not think that we, as a nation, shall be taking our proper share of the highest scientific work of the world until such an institution is started on its

There is only one evil which, so far as I can see, is to be feared from it if ever it were allowed to impose on outside workers as a central authority, from which infallible dicta were issued, it would be an evil so great that no amount of good work carried on by it could be pleaded as sufficient mitiga-

tion If ever by evil chance such an attitude were attempted, it If ever by evil chance such an attitude were attempted, it must rest with the workers of the future to see that they permit no such shackles; for if they are not competent to be independent, and to conteaun the vace of authority speaking as mere authority, if their only safeguard hes in the absence of necessity for struggle and effort, they cannot long hope to escape from the futility which surely awaits them in other directions.

I am thus led to take a wider range, and, leaving temporary and special considerations, to speak of a topic which is as yebyond the pale of scientific orthodox, and which I might, more wisely, leave lying by the roadwide. I will, however, take the rask of introducing a rather ill favoured and disreputable looking stranger to your consideration, in the belief-I might say, in the assured conviction—that he is not all scamp, and that his present condition is as much due to our long-continued neglect

as to any inherent incapacity for improvement in the subject.

I wish, however, strenuously to guard against its being supposed that this Association, in its corporate capacity, lends its posed that this Association, in its corporate capacity, itemas-incountenance to, or looks with any favour on, the outcast. What I have to say—and after all, it will not be much—must rest on yown responsibility. I should be very sorry for any adventitious weight to attach to my observations on forbidden topics from the accident of their being delivered from this fails. The from the accident of their being delivered from this chair. The objection at which I have now hinted is the only one that seems objection at which I have now hinted it the only one first stems to the read by six weight, and on all other counts I am willing to mear such amount of opprobrium as naturally stuckles to those who enter on a region where the first of controversy are not extract, and in which it is quite impossible, as well as undesarble, for everyone to think alika. But the control of the contr

should ever be allowed to obtrude itself before us Our ancestors should ever be allowed to obtrude itself before us. Our ancestors togeth hard and suffered amon for the privilege of free and open inquiry, for the right of conducting investigation untransmelled reasons and the property of the conducting investigation untransmelled and the conducting the c mediately adjacent thereto, were to end in our losing the power of raining our year and recovering evidence of a totally fresh processes of the processes of the processes of mounty as each evidence of regions into which the support of the processes of mounty as each evidence of the processes of

For instance, there is the question whether it has or has not been established by direct experiment that a method of communication exists between mind and mind irrespective of the ordinary and, if so, what is the process It can hardly be through some unknown sense organ, but it may be by some direct phycon- unknown lean-regard, but may be by some direct physical indicates on may be by some direct physical indicates on the page of the may be by some direct physical indicates on the page of the page

the recognized scientific societies who would receive a paper on the subject 1. There are individual scientific men who bave

investigated these matters for themselves ; there are others who are willing to receive evidence, who hold their minds open and their judgment in suspense, but these are only individuals. The great majority, I think I am right in saying, feel active hostility to these recearches and a determined opposition to the reception or discussion of evidence. And they feel this confirmed

scepticem, as they call it, not after prolonged investigation, for then it might be justified, but sometimes after no investigation of at all. A few tricks at a public performance, or the artifices of tome impostor, and they decline to consider the matter further That individuals should take this line is, however, natural enough ; they may be otherwise occupied and interested

body is by no means bound to investigate everything, though, indeed, it is customary in most fields of knowledge for those who have kept aloof from a particular inquiry to deter in moderation to those who have conducted it, without feeling themselves called upon to express an opinion. Some there are, no doubt, who cognider that they have given sufficient time said attention to the subject with only negative results. Their evidence is, of course, morportant; but plantly, negative evidence should be of immense bulk and weight before it can outweigh even a moderate amount have kept aloof from a particular inquiry to defer in moderation to bulk and weight before it can outweigh even a monerate amount of positive evidence. However, it is not of the action of individuals that I wish to speak, it is of the attitude to be adopted by scientific bodies in their corporate capacity, and for a corporate body of men of science, inheritors of the hard-won tradition of free and fearless inquiry into the facts of nature tradition of free and fearless inquiry into the facts of nature untrammelled by prejudec, for any such body to decline to receive evidence laborously attained and discreetly and in-offensively presented by observer of accepted competency in other branches, would be, if erer actually done and persisted in, a terrible throwing away of their perogative, and an instation of the errors of a school of thought against which the struggle was at one time severe.

struggle was at one time server.

In the early days of the Copernican theory, Gahleo for some years reframed from teaching it, though fully believing its truth, because he considered that he had better get more fully settled in his University chair before evoking the storm of controversy which the abandonment of the Tolemaic system would arouse. The same thang in very more degrees is going on to day. Then the control is not the same thang in very more degrees in these new laveringstons of men who behalts to a vow introcts in these new laveringstons.

1 This, however, is mere conjecture I am not aware that the experiment

NO. 1138, VOL. 447

(I do not mean eredence—the time is too early for avowing tained facts—but hesitate to avow interest) until they have settled tained facts—but nestitate to avow interest) until mey nave setuted down more securely and made a name for themselves in other lines. Caution and slow progress are extremely necessary; fear of avowing interest or of examining into unorthodox facts is, I venture to say, not in accordance with the highest traditions of

the scientific attitude

the scendific attitude.

We are, I supposed of once extent afraid of each other, but
We are, I supposed of once the state of each other, but
the opinions of our elders and superiors, we find the opinions of our elders and superiors, we find the opinions of our elders and superiors, we find the opinions of our other, so we are silent. We have, moreover, a righteous mastruis of our own powers and knowledge, we perceive that it is a winder region extending into everal already cultivated that it is a wise region extensing into several arready cuturwater branches of science, that a many-sided and highly trained mind is necessary adequately to cope with all its ramifications, that in the absence of strict inquiry impositure bas been rampent in some portions of it for centuries, and that unless we are pre-terraturally careful we may get led into quaginites if we venture on it at all

on at airli

Now let me be more definite, and try to state what this field
is, the exploration of which is regarded as so dangerous I

Now let me to the state of the state of the state of the state
and the state of the state o and medicine. An occasional psychologisi has groped down and into it and become a metaphysician. An occasional physicist has wandered up into it and lost his base, to the horror of his quondam brethren. Biologists mostly look at it askance, or deny its existence. A few medical practicumers, after long maintenance of a miniar attitude, have begun to annex a portion of its western frontier. The whole region seems to be inhabited mainly by savages, many of them, so far seems to be inhibited mainly by awages, many of them, "of as we can page from a distance, given to gross supersistion. It may, for all I know, have been hastly traversed, and radely continued to the control of the co

writings may, when interpreted, mean much But to us, as physicists, they are unsatisfactory, their methods are not our methods. They may be said to have floated a balloon over the physiciss, my my may be said to have floated a balloon over use received in the phase caught received and fragments glass statehed, in which they have caught received and fragments glass to the phase per part of the phas

iar more than they saw
Our method is different
We prefer to creep slowly from our
base of physical knowledge, to engineer carefully as we go,
exhibiting fors, making roads, and thoroughly exploring the
country; making a progress very slow, but very lasting. The
psychologists from their side may meet us. I hope they will,
but one or other of us ought to begin.

but one or other of us ought to begin.

A valuerable spot on our side seems to be the connection between life and energy. The conservation of energy has been so long established as to have become a commonplece. The relation of life to energy is not understood. Life is not energy, and the death of an animal affects the amount of energy no whit, yet a live animal exerts control over energy which a dead one a live animal exerts control over energy which a dead one cannot Life it a guiding or directing principle, disturbing to the physical work but not yet given a place in the scheme performance of work; the guidine of energy needs no work, but demands force only. What is force? and how work but demands force only. What is force? and how worked by the demands force only when the force of the material control of the control of the control of the material control of the control of the control of the material control of the control of the control of the material control of the control of the control of the material control of the contr worked by preceding conditions—that is, soy the past—my un-materizable. After we so user that they are not worked by the feature too? In other words, that the totality of things, by where the sax well as the past, and that to attempt to deduce those actions from the past only will prove impossible. In some way matter can be moved, guided, disturbed, by the segancy of ling beings; is is some way there is a control, a directing-agency active, and remains are tassed at its choice and will that would not otherwise happen.

* The expression "controlled by the future" I first heard in a conversation with G. F. Fetagerald, who seemed to consider it applicable to all avents, without exception

A luminous and helpful idea is that time is but a relative mode of regarding things, we progress through phenomena at a certain defin to pace, and this subjective advance we interpret in an stenn to pace, and this subjective advance we interpret in an objective manner, as if events necessarily happened in this order and at this precise rate. But that may be only one mode of regarding them. The events may be in some sense existent always, both past and future, and it may be we who are arriving atways, both past and future, and it may be we who are arriving at them, not they which are happening. The analogy of a traveller in a rativacy train is useful. If he could never leave the train nor after its pace, he would probably consider the landscapes as necessarily successive, and be madde to conceive their co existence

The analogy of a solid cut into sections is closer The analogy of a solid cut into sections is closer We recognise the universe in sections, and each section we call the present. It is like the string of slices cut by a microtome, it is our way of studying the whole. But we may err in supposing that the body only exists in the slices which pass before our microscope

in regular order and succession.

We perceive, therefore, a possible fourth dimen-lonal aspect about time, the inexorableness of whose flow may be a natural part of our present limitations. And if once we grasp the idea that past and future may be actually existing, we can recognise that they may have a controlling influence on all present action, and the two together may constitute "the higher plane," or the totality of things, after which, as it seems to me, we are impelled to seek, in connection with the directing of force or determinism, and the action of living beings consciously directed to a definite

and preconceived end.

186

Inanimate matter is controlled by the vis a lergo, it is operated on solely by the past. Given certain conditions, and the effect in due time follows. Attempts have been made to the effect in due time follows. Attempts have been made apply the same principle to living and conscious beings, but without much succe s. These seem to work for an object, even if it be the mere seeking for food; they are controlled by the idea of something not yet palpable. Given certain conditions, and the section control are successful than the section of the conditions are the section of and their action cannot certainly be predicted; they have a sense of option and free will Either their actions are really arbitrary of option and free will Either their actions are really arbitary and indeterminate—which is lightly improbable—or they are controlled by the figture as well as by the pisa! Inagine bongs they will be invogrationate, and will eithbit all the characteristics of live creatures. Moreover, if they have a meterly expensionate and the characteristics of live creatures. Moreover, if they have a meterly expensionate havoring, necessarily intended by memory and bounded by the past, they will be unable to predict each under's actions with any creaturally, because the whole of the datas are not before the control of the control of the control to the control of the contr them May not a clearer apprehension of the meaning of life and will and determinism be gradually reached in some such direction as this?

By what means is force exerted, and what, definitely, is my what means is force exerted, and what, definitely, is force? I can lardly put the question here and now so as to be intelligible, except to those who have approached and thought over the same disculties, but I venture to say that there is here something not provided for in the orthodox scheme of physics, that modern physics is not complete, and that a line of possible advance her in this direction.

I might go further Given that force can be exerted by an act of will, do we understand the mechanism by which this is done? And if there is a gap in our knowledge between the conscious idea of a motion and the liberation of muscular energy needed to accommotion and the liberation of mutualar energy needed to accom-plifit, in low one know that is bodying up to the more dwinfout that such a thing is possible. I have tired once or twee to ob-serve its asserted occurrence, and failed to get anything that satisfied me. Others may have been above fortunate. In any decay the possibility. If the conservation of centry were upset by the process, we should have grounds for denying it. I such that the contract of the contract of a novel of a novel nobling that we know it speet by the discovery of a novel modium of communication, perhaps some more immediate action medium of the communication perhaps some more immediate action cline to examine phenomena because we feel too stare of their moustability. We ought to know the universe very thoroughly and completely before we take up that attracts and outside the perhaps that the perhaps the perhaps

This 14, of course, not assertion, but suggestion. It may be error to draw any such distinction between ammate and intermale

writing, or in other ways. A prearranged code called language, and a material medium of communication, are the recognised methods. May there not also be an immaterial (perhaps an ethereal) medium of communication? Is to possible that an idea can be transferred from one person to possible that an idea can be transferred from one person to another by a process such as we have not yet grown accustomed to, and know practically nothing about? In this case I have evidence I assert that I have seen it done, and am perfectly convinced of the fact. Many others are satisfied of the truth of it too. Why must we speak of it with bated breath, as of a thing, of which we are sishamed? What right have we to be ashamed of a truth?

ashamed of a truth?
And after all, when we have grown accustomed to it, it will not seem slogether strange. It is, perhaps, a natural consequence of the community of life of family relationship raining through all living beings. The transmission of slightening through all living beings. The transmission of slightening through all living beings, the transmission of slightening and all magnets are sympathetically coinceted, to this if voirably are perioded arterization from our disturbs others, even though they

be distant ninety-two million miles

It is sometimes objected that, granting thought-transference or telepathy to be a fact, it belongs more especially to lower forms of life, and that as the cerebral hemispheres develop we become independent of it, that what we notice is the relic of a decaying faculty, not the germ of a new and fruitful sense; and that progress is not to be made by studying or attending to it.

It may be that it is an immature mode of communication, adapted It may be that it is an immature mode of communication, anapter to lower stages of consciousness than onrs, but how much can we not learn by studying immature stages? As well might the objection be urged against a study of enhypology I may, on the other hand, be an indication of a higher mode of communi-cation, which shall survive our temporary connection with ordinary matter

I have spoken of the apparently direct action of mind on mind, and of a possible action of mind on matter. But the whole region is unexplored territory, and it is conceivable that matter may react on mind in a way we can at present only fimly imagine In fact, the barrier between the two may gradually melt away, as so many other harriers have done, and we may end in a wider perception of the unity of nature, such as

cou in a winer perception of the unity of nature, such as philosophers have already dreamt of. I care not what the end may be shall be conducted by us, and that we shall be free from the diagrace of jogging along accustomed roads, leaving to outsiders the work, the ndicule, and the grantification, of unfolding

a new region to unwilling eyes

a new region to unwilling eyes
It may be held that such investigations are not physical and
do not concern as. We cannot tell without pring. In that I
do not concern as a physicasts. It may concern other
which does concern us as physicasts. It may concern other
sciences too. It must, one would suppose, some day concern
biology, but with hat I have nothing to do. Bhologusts have
their region, we have ours, and there is no need for us to hang
hack from an investigation because they do. Our own steenes, of Physics or Natural Philosophy in its widest sense, is the King of the Sciences, and it is for us to lead, not to follow

And I say, have faith in the Intelligibility of the universe Intelligibility has been the great creed in the strength of which all intellectual advance has been attempted, and all scientific

progress made.

At first things always look mysterious. A comet, lightning, the At first things always look mysterious. A comet, lightning, the autora, the rainbow—all strange anomalous mysterious appartions. But scrutinized in the dry light of science, their relationship with other better-known things becomes apparent. They cease to be anomalous; and though a certain mystery

necessarily remains, it is no more a property peculiar to them, it is shared by the commonest objects of daily life. The operations of a chemist, again, if conducted in a hap-hazard manner, would be an indescribable medley of efferves a concentration of the chemist, again, if conducted in a hap-hazard manner, would be an indescribable medley of efferves. ansatz manner, would be an indescribate medicy of energe-cences, precipitations, changes in colour and in substance; but, guided by a thread of theory running through them the processes fall into a series, they all become fairly intelligible, and any explosion or catastrophe that may occur is capable of explanation

Now I say that the doctrine of ultimate intelligibility should Now I say that the doctrine of ultimate intestigating since be pressed into other departments also At present we hang back from whole regions of inquiry, and say they are not for us. A few we are beginning to grapple with. The nature of disea e is yielding to scrutup with fruitful result; the mental aberrations and abnormalisties of hypotolism, duplex personality, and allited phenomena, are now at last being taken under the wing of science after long riducile and contempt. The phenomenon of crime, the scientific meaning and justification of altrulam, and other matters relating to life and conduct, are beginning, or perhaps are barely yet beginning, to show a vulnerable from

pernaps are narely yet beginning, to show a vulnerable from over which the forces of science may pour Facts to airsinge that they have been called miraculous are now no longer regarded as entirely incredible. All occurrences seem reasonable when contemplated from the right point of view, and some are believed in which in their essence are still quite marvellous. Apply warmth for a given period to a sparrow's egg, and what result could be more incredible or magical if now discovered for the first time. The possibilities of the universe are as infinite as is its physical extent. Why

of the universe are as immire as a large should be grope with our eject always downward, and deny the possibility of everyining out of our accustomed best. If there is a puzzle about free will, let it be attacked, puzzles mean a state of half knowledge, by the lime we can grant something more approximating to the totality of things, the paradoxity of paradoxes drops away and becomes unrecognizable I seem to myself to catch glimpses of clues to many of these old questions, and I urge that we should trust consciousness, which has led us thus far, should shrink from no problem when the time seems ripe for an attack upon 11, and should not hestate to press investigation, and agcertain the laws of even the most recondite problems of life and mind

recondite problems of life and mind.

What we know is as nobling to that which remains to be known. This is sometimes said as a trusm, sometimes it is half doubted. To me it seems the most literal truth, and that if we narrow our view to already half conquered territory only, we shall he false to the men who won our freedom, and treason-

able to the highest claims of science
I must now return to the work of this Section, from which I have apparently wandered rather far afield, further than is customary—perhaps further than is descrable. But I hold that occssionally a wide outlook is wholesome, and that without such occasional survey, the rigid attention to detail and minute scrutiny of every little fact, which are so entirely admirable and are to rightly here fostered, are apt to become unhealthily dull and monotonous. Our life works is concerned with the rigid framework of facts, the skeleton or outline map of the universe tramework of facts, the sketeton or outline map of the universe and, though it is well for us occasionally to remember that the texture and colour and beauty which we habitually ignore are not therefore in the slightest degree non-existent, yet it is safest speedily to return to our base and continue the slow and laboraous march with which we are familiar and which experience has instified justified It is because I magine that such systematic advance is now beginning to be possible in a fresh and unexpected direction that I have attempted to direct your attention to a subject which, if my prognostications are correct, may turn out to be one of special and peculiar interest to humanity

THE LATE PROF. MARTIN DUNCAN, F.R.S. X/E have already announced the death of this wellknown geologist, and now give a brief account of his services to science.

As a Fellow of the Royal, Linnean, Geological, and Microscopical Societies, and for some time President of the two last-named of these, it goes without saying that his attainments were of no mean order. Educated for the medical profession at King's College, London, he matriculated at the London University in 1841, taking honours in anatomy and physiology in 1844, and the degree of Bachelor of Medicine in 1846, in which year also he qualified as a Member of the Royal College of Surgeons His early life was passed at Rochester with Dr. Martin, and at Colchester, where he was in practice for some years, and where he so won the esteem of all who knew him that he was elected Mayor of that city Fascinated with the study of geology, and impressed with the idea that to make any mark in the scientific world a man should take up some spécialite, he not only obtained a broad grasp of his favourite subject, but devoted himself especially to a study of fossil corals and echinoderms, on which subjects at intervals he published numerous valuable memoirs Indeed, for many years, and up to

within a comparatively short period of his death, he conwithin a comparatively stori period of instealin, he con-tinued to work at his sperial subject, and contributed many important papers to the Annals and Magazine of Autural History, the Journal of the Geological Society, the Geological Magazine, Quarterly Journal of Micro-sophical Science, the Philosophical Transactions and Proceedings of the Royal Society, the Proceedings and Transactions of the Zoological Society, and the Journal of the Linnean Society

He soon found that residence out of London, away from scientific societies and important works of reference. was a great obstacle to work, and that if he was to make any real progress with his special studies it was absolutely necessary for him to seek some appointment in the metro-polis Portunately for him, as it happened, the Chair of Gology at King's College became vacant, and he was appointed to fill it. This at once gave him the oppor-tunity he had so long hoped for, and the preparation of his lectures proceeded side by side with much useful work, which, by degrees, he found time to publish. Such, for example, was his account of the Madreporaria collected during the expedition of H M S Poscupine, which appeared in the Transactions of the Zoological Society (Part 1, vol viii p 303, &c, and Part 2, vol x p 235, &c), his description of deep-sea and litoral corals from the Atlantic and Indian Oceans (Proc Zool Soc, 1876, p. 428, &c); and his important revision of the Echinoidea, printed in the Journal of the Linnean Society, of which it occupied four numbers

This was all strictly scientific work, but by no means represented all that he accomplished. As a popular exponent of the teaching of geology and zoology, especially in regard to the lower forms of life, he published many excellent articles which were designed to awaken an interest in subjects little investigated, though well worthy of attention.

Lucidly written and full of facts, these articles were at once instructive and suggestive, and from a teachers' point of view did more to educate youthful naturalists and encourage research than any of his more scientific papers, which, being of a more technical character, were less acceptable to the majority of readers because less intelligible to them

Of this class were his articles on "Corals and their Polypes" (Intellectual Observer, 1869, pp 81-91, 241-50, with two coloured plates), "Studies amongst Ameche" (Popular Science Review, 1877, with two plates), and "Notes on the Ophiurans, or the Sand and Brittle Stars"

(Popular Science Review, 1878, with a plate)
lits attention, however, was not confined to invertebrate 200logy or geology. In 1878 he commenced the publication, in six volumes quarto, of a popular " Natural History," which had the ment of being written by a number of able specialists upon a comprehensive plan under his direction, and, while taking upon himself the laborious duties of editor-in-chief, he contributed many of the sections himself Thus, while securing the cooperation of such well-known zoologists as the late Prof. W. K. Parker, the late Mr. Dallas, Prof Seeley, Prof. Boyd Dawkins, Dr. H. Woodward, Dr. Murie, Mr. H. W. Bates, and Mr. R. B. Sharpe, he himself undertook the preparation of the articles on Apes and Monkeys, Lemuis (part), Edentata, Marsupialia, Reptilia, and Amphibia He also wrote the introduction to the Invertebrata, and the articles Vermes, Zoophytes, and Infusoria which appeared in the last volume, published in 1883.

For an excellent summary of marine zoology, in which the appearance, structure, and habits of such animals the appearance, structure, and mabits of such animals and plants as may be found upon our coasts are well described, the reader may be referred to a little volume by Dr Duncan, entitled "The Sea shore" It forms one of a series of "Natual History Rambles," issued a few years since by the Society for Promoting Christian Knowledge, ard, for the amount of information which it contains, as well as for its lucid expression, deserves to be better known

Dr. Marin. Duncan was undoubtedly one of the working bees in the great hive of science; and in his own quiet, unostentations way has stored up a considerable amount of material the value of which will be more and more appreciated as those for whose benefit it was accumulated come to examine and understand it.

In his ardent devotion to science, and patient industry in spite of trials and troubles which would have deterred many less earnest workers, he set a bright example, which those of a younger generation of naturalists would do well to follow

NOTES

IT seems that those members of the Government, whichever they may be, who are responsible for buildings for scences and art, have determined to even new galleries for the Art Museum at South Kennington, practically to cover all the ground which is supposed to be applicable for art purposes there. These buildings are to cost some £40,000, and, when this moving it a special to the suppose the South Kennington Art Museum will be finished by the suppose, also, that the building of a Science Museum will by this action, be delayed for another twenty years. This will be a great victory for art, and will afford another interesting example of the results of the way in which matters scientific are managed in this country.

Ms. EDAN. TRUNKTON, Curator of the Government Museum at Madras, has been appointed to officiate for two years for Dr. Watt, at Calcutta, in reporting on economic products and organizing collections of products and manufactures for the Calcutta and other Indian Museums, in dutte at Madras being in the meantime discharged by Dr. Warth, of the Geological Department.

PROF GOEBEL, of Marburg, has been appointed to the Chair of Botany at Munich in succession to the late Prof Naegeli.

WE regret to announce the death of Dr. Weiss, the Professor of Botany and Director of the Plant Physiological Institute of the University of Prague

THE late Cardinal Haynald's important herbanum and botanical library has been placed in the National Museum at Budapest

WE learn from Madras that the observations made under the direction of the late Mr. Pogson are in a forward state of reduction, and that the real activity of the Observatory is not to be measured by the fact that the last published volume of Observations contains the record of those made in 1870. The funds at the disposal of the Madras Observatory have not permitted the regular and early publication of the masses of observations which the industry of Mr Pogson and his assistants has accumulated, and the scheme which the Director proposed to himself did not permit him to give, from time to time, an abstract of his work through the ordinary and recognized channels open for the dissemination of astronomical results. Mr. Michie Smith writes that the "Variable Star Atlas" alone contains the observations of about 60,000 stars, made and reduced by Mr Pogson. We may express an earnest wish that no long time may be suffered to elapse before astronomers have an opportunity of judging the value of this mass of material in an interesting branch of astronomical inquiry.

UNDER the McKinley rigame it seems to be a very generous this for an Austrian second to communicate a paper to a British society-fibe of them writes as follows to the Nation—
"A learned society of Scotland, in pursuance of its liberal policy, mailed to me fifty author's copies of a paper which had been honoured by admission to its Transactions. The bandle

came to the local post-office this week opened, and accompanied by a slip gring the package a commensial value "of waive dollars, and assessing a duty of as per cent. The local collector of customs thicks that I am resisting the just claims of a hardworking Government in delaying payment; but curiosity as to how they discover the commercial value of a paper whose real audience might, I think, be numbered on the fingers of the two hands, has teld me to appeal the case.

Science states that the executors of the estate of the late William B Ogden, the first Mayor of Chicago, have selected the University of Chicago as one of the beneficiaries, giving it a scientific school. The gift, which will amount to from three hundred thousand to half a million dollars, will endow a separate department of the University, to be called the Orden Scientific School, its purpose being to furnish graduate students with the best facilities possible for scientific investigation by courses of lectures and laboratory practice. The income of the money appropriated is to be devoted to and used for the payment of salaries and fellowships, and the maintenance of laboratories in physics, chemistry, biology, geology, and astronomy, with the subdivisions of these departments A large share of the time of the professors in the school is to be given to original investigation, and encouragement of various kinds is to be furnished them to publish the results of their investigations, a portion of the funds being set apart for the purpose of such publication.

It seems as if in time the publishers of sea-side guides may realize that some people who require a holiday are intelligent, possess eyes, and perchance even some acquaintance with natural history We have just received a copy of Johnson's illustrated 'Visitors' Companion" to Eastbourne and its vicinity, which contains, besides the matter usually supplied, an account of the flora, consisting of 291 varieties of wild flowers, 9 orchids, 18 ferns, 12 mosses and their allies, 34 varieties of sea-weeds (with directions for collecting and preserving them), particulars are also given of 56 varieties of butterflies (with time of appearance), 45 varieties of moths (with time of appearance, and how to catch them by the electric light), 29 varieties of wild bees, pebbles, fossils, land and freshwater mollusca, a brief geological survey of the district, and an extensive list of wild birds which frequent the neighbourhood, together with a guide to fresh and salt water fishing. Have we to thank Prof Huxley's local influence for this

As achistion of the successes in aclimatination achieved in Runsi will be opened at Macow, in connection with the International Congresses of Zeology and Perhatoric Archeology and Anthropology which will be held in the Russian capital in August 892. The results of the numerous experiments in accinuatization of a great variety of plants which have been made during the last twenty-five years, especially in the Ansatre domaintoin of the Empire, will be exhibited.

IN a Vice-Presidential Report to the U.S. National Geographic Society, on the "Geography of the Air," Lieut. A. W. Greely reviews the progress of meteorological science during the past year, chiefly with reference to the work of American meteorologists. Referring to the recent controversy on the causes of cyclones and anticyclones, he says :- "The status of the meteorological discussion which has been going on for some time seems to be this A number of men, applying themselves to investigation in separate branches or stages of the same science, are attempting to reconcile their views, which, based as they are upon entirely different processes of investigation, are not entirely accordant. Some at least of these writers are still apparently groping in the preliminary, the 'natural history' stage of the science of meteorology, while one alone stands as the exponent of the 'natural philosophy' of meteorology." This view ems somewhat Inappreciative, and the account given of Dr. Hann's work inadequate and not quite correct. Dr. Hann's memoir demonstrated that the temperature conditions of antievelones, and probably extra-tropical evelones are inconsistent with the convectional hypothesis as worked out by Prof. Ferrel, and he suggested as an alternative that their cause is to be sought in the general circulation of the atmosphere. But he did not originate this view, which had been put forward long before by Werner Siemens; nor did he attempt to develop it. It is incorrect, therefore, to represent this hypothesis as the main object of his memoir In connection with the work of the Weather Bureau, of which Lieut. Greely is Director, he notices the experiments of Prof. Marvin on wind pressures and velocities, which confirm the results of some previous experimenters in proving that the indications of the Robinson anemometer are too high, also that pressures computed from velocities by the usual formula are much in excess of the truth , the result being that the pressure computed from the readings of the Robinson anemometer, when the actual velocity is sixty miles per hour, is 50 per cent. too high. Other subjects briefly noticed are Finley and Hazen's work in connection with tornadoes, and Prof Russell's on cold -

In a pamphlet entitled "Physical and Geological Traces of Permanent Cyclone Belts." Mr. Marsden Manson treats of a somewhat large subject in the small space of ten pages. Starting with the assumption that the main features of the barometric zones of the earth have been the same throughout past ages as they are at the present day, and that there has always been a belt in the north temperate zone, between 50° and 60° N. lat , which is the mean track of maximum evelone frequency and low mean pressure, he infers that, owing to the diminished pressure, this has always been an axis of upheaval, and at the same time, owing to excessive precipitation, a zone of maximum denudation. His ideas are apparently suggested by the geological structure, the orographic and meteorological features of North America, and little or no attempt is made to verify his inferences by the geological and meteorological conditions of Europe and Asia, which hardly seem to bear out his hypothesis, Thus he instances the Archiean axis of Canada as the secular result of upheaval and denudation along an axis roughly coinciding with the average storm track, but he omits to show any similar relations between the Archiean rocks of Bohemia or the Alpine chain and the average course of storms in Europe. It is, however, altogether premature to criticize a theory put forward in so crude a stage of development, and it is hard to see what service can be rendered to science by such premature publica.

DR W DOBERCK has published the observations made at the Hong Kong Observatory in the year 1889 Returns were received from forty land stations, and extracts from logs of ninety three ships which visited Chinese waters were collected during the year, and will be utilized in investigations of the meteorology and typhoons of the Eastern seas. The stations in connection with maritime meteorology extend to the Island of Luzon, and a most valuable station has been established on the rsland of Formosa, by the Chinese Maritime Customs The observations of the rain-band have been regularly continued. and have been found of use both in prediction of fine weather and of heavy thunderstorms An advance Report Issued for 1890 shows that considerable improvement in the storm-warning service has been effected by the connection of the Observatory with the telegraph offices A committee of inquiry which sat in the early part of 1890, has recommended that more financial and other assistance be given to Dr Doberck in carrying out his work.

THE Central Meteorological Office of Paris has recently published its *Annales* for the year 1888, consisting of three NO. 1138, VOL. 447

large quarto volumes. Vol 1 contains -A discussion by M Fron on the character of the thunderstorms of the years 1887 and 1888, with charts for each day on which such storms occurred . a review by M. Moureaux of the magnetic observations at Park of Saint Maur, together with factimile curves of the most interesting disturbances Owing to an agreement with Greenwich Observatory, the curves published in this country and in brance will generally correspond to the same disturbances, and will therefore allow of interesting comparisons Résumés of the magnetic observations made at 53 other stations in France are also published. A discussion by M. Angot of the phenological and other periodical phenomena during the years 1886 and 1887 These observations have now been continued for eight years, M. Ancot has also studied the effect of the amount of cloud on the daily variation of temperature at Paris A paper by M. Raulin on the seasonal rainfall of various countries in Europe. in which he shows that when a number of years are taken into consideration the condensation of vapour follows a regular scasonal range, with a minimum in winter and a maximum in summer, where the range is not interfered with by secondary causes, such as proximity to the sea, &c M Teisserenc de Bort presents a paper on the mode of formation of types of sobars, and on the theory of the general circulation of the atmosphere, illustrated by diagrams Vol. ii contains the observations made at various stations and mountain observatories, including also several stations in Algeria, Egypt, Panama, &c Vol in contains values of rainfall at a large number of stations, with monthly, seasonal, and annual charts. The actual number of stations reaches nearly 1800, and daily values are published for 925 stations

A NAMARKABLE weather change is reported to have occurred at Orenburg on November 19, 1890. After a temperature of 3°C, with beavy run, there was a fail to - 30°C in 20 minutes. Some thirty Kirghines, who were returning to Orenburg, were drenched with the rain, then frozen on their horses. Ten of them had been found, and the others were being sought for. Many horses and other animals succumbed to the cold

SNOW DRIFTS are found a serious disturbance of the Russian railway system With a view to forecasting such occurrences, M Sresnewskii has lately collected information about snowdrifts on the Russian lines during 1879-89 (Rep. fur Met.) The drifts occur in the Northern and Eastern Governments, chiefly with south-west wind, but in Southern Russia with north-east, In the north, greater gradients are required than in the south. The maximum of the drifting is in mid winter, but there is more in the second half of winter than in the first, that having more snow. In course of wirter the snow grows in thickness, so that in March there is more to drift than in December. The marked diminution of drifting in February is due to the less wind in that month (a fact not yet explained, as the number of cyclones shows no decrease) Two kinds of drifting are distinguished, it may be only or chiefly snow lying on the ground that is whirled and carried along, or the wind may drive falling snow. There are most drifts in the months that have least snowfall and the smallest number of days of snow. The snow-drifts in South Russia with north-east wind are chiefly connected with anticyclones in the central region, or cyclones on the southern border, those in the east and north with cyclones in European Russia In Central Russia they occur with cyclonic winds of various direction, seldom with anticyclones.

An investigation (more comprehensive than the previous ones by Forel, Fritz, and others) of the variations of Alpine gladiers, has been recently made by Herr Richter, of the German and Austrian Alpine Clinb To six advances of glaciers, previously known, he adds three, and his account of the six differs somewhat from previous ones. The dates of commencement of the nine advances are 1592, 1630, 1675, 1712, 1735, 1767, 1814, 1835, 1875 (2). The following are some of Richter's conclusions -- Glacier advances recur in periods varying between twenty and forty five years , on the average of three centuries, thirty-five years. The advances are not all of equal intensity. nor allke in their progress. Nor is the intensity in a given advance period the same in all glaciers. In the case of some glaciers, a period is occasionally skipped, the advance or retirement being very weak, so that the thirty-five years period gives place to one of seventy years. The glacier variations corre-spond, in general, with Bruckner's climate variations. The glacier advance generally begins a few years after the moist and cool period has set in. There is no good reason to suppose that, in historic time, before the sixteenth century, the Alpine glaciers were smaller than now, or that variations occurred of different order and period from those of the last 300 years. About 1880, the earth was passing through a moist and cold period, which should have resulted in a general advance, but the advance has been but slight hitherto, and, in the Eastern Alps, mostly absent. The cause of this is not at present clear. but the mild nature of this last cold period may have something to do with it

THE bacillat of tuberculous, it is known, is often to be found in places lived in by consumptives Herr Pranaunt has lively collected the dux in various compartments of trains which often convey patients from Berin to Marra, and inoculated a number of guine-pigs with it. Two, out of five compartments we examined, were found to contain the bacillats, the dust of one rendered three out of four guine-pigs suberculous, that of the battle out of the compartments were a substantially and the substantial training the capter of mail. The fact, however, seem to point to the necessity of disinfaction of such railway cartiages, eventably the expects or mail.

To the usual well-known ways of stimulating muscles to con raction, viz electrical, thermal, mechanical, and chemical, M D'Arsonyal has recently added that by means of light. He could not, indeed, get any contraction to a fresh frog-musclewhen he suddenly threw bright light on it in a dark chamber; but having first in darkness stimulated a muscle with induction currents too weak to give a visible effect, and then suddenly illuminated the muscle with an arc light, the muscle showed slight tremulation. Not thinking this conclusive, however, M D'Arsonval attached a muscle to the middle of a piece of skin stretched on a funnel, and connected the tube of the funnel by means of a piece of india-rubber tube with the ear. The muscle being now subjected to intense intermittent light, he heard a tone corresponding to the period of illumination, and this ceased when the muscle was killed with heat. Arc light was used, which was concentrated by a lens and passed through an alum-solution to stop the heat rays

FOR nearly two years there has been at work in Denver, Colo, an automatic refigerator system, which seems to be thoroughly successful. Ammoniscal lugor in the proportion of 29 parts present in Stored through a nann to the policy of the proportion of 29 parts and the proportion of 29 parts and the proportion of 29 parts affected there for quick supermixtun, and after absorption by afforded there for quick supermixtun, and after absorption by water, the luquid returns by section to the central station. There are not mits of mains having connection with tenstyrance boxes, each containing a grill near the top to which the luquir is thouch the proportion of the proportion of the state of th

clean, the moisture collects on the grill as frost. In one experiment a piece of meat was kept six mopths and then cooked and eaten, and it seemed no way different from fresh meat

THE French Sociéte de l'Encouragement lately offered a prize of 1000 france for conservation of potatoes and other vegetables. Four of the five applicants used some isolating substance (woodash, sawdust, rve-straw with sand). M. Schribaux, who calned the prize, puts potatoes for ten hours in a 11 per cent solution of commercial sniphuric acid to kill the buds (a 2 per cent. solution for thick skins). The potatoes are taken out and thoroughly dried, and they will keep without alteration more than a year. The same solution serves for repeated immersions, the concentration remaining constant. The process is not applicable to Another prize by the same Society (3000 francs) is awarded to M Candlot for a memoir treating of the action of sea-water on cements. He shows that the sulphate of lime resulting from decomposition of sulphate of magnesia by limesalts of the cement combines with aluminate of lime to give a double crystalline salt containing half its weight of water. The crystallization of a salt so greatly hydrated involves considerable swelling, and this accounts for the disaggregation of cements in marine work M Candlot has observed the curious fact that over baked lime, which takes several days to extinguish in water, is extinguished in a few minutes in a 3 per cent solution of chloride of calcium. This is thought to have important practical bearings.

M RASPAII has lately called attention, in the Zoological Society of France, to the serious diminution of birds in that country through destruction of their nests. Some insectivorous species are becoming very rare, while the rayages of parasites on useful plants are extending Boys, of course, do a great deal of the mischief, and of the various animals which attack nests (the squirrel, the hedgehog, the dormouse, the magnie, &c) M Raspail regards the cat as the worst offender On a recentlywooded property of about 7 acres he observed last year as follows -Out of 37 nests, carefully watched, only 8 succeeded : 29 were destroyed, 14 of these by the cat, though effort had been made to ward off this insatiable marguder. On a large property in the centre of a village the owner had about 80 cats annually caught in traps. The place having lately changed hands, the gardeners estimate that more than 100 Bests were destroyed last year, three fourths of these by cats M. Raspall advocates a rigorous application of the law for protection of insectivorous species, the disqualification of the cat as a domestic animal, and the giving of prizes to foresters and others for destruction of all animals which prev on eggs and young in the

TOBACCO fermentation, a very essential process, is brought about by firmly packing ripe tobacco in large quantities. It had been generally supposed that the fermentation is of purely chemical nature, but Herr Suchsland, of the German Botanical Society, finds that a fungus is concerned in it. In all the tobaccos he examined, he found large quantities of fungi, though of only two or three species Bacteriacese were predominant, but Coccacese also occurred. When they were taken and increased by pure cultivation, and added to other kinds of tobacco, they produced changes of taste and smell which recalled those of their original nutritive base. In cultivation of tobacco in Germany it has been sought to get a good quality, chiefly by ground cultivation, and introduction of the best kinds of tobacco. But it is pointed out that failure of the best success may be due to the fact that the more active fermenting fungi of the original country are not brought with the seeds, and the ferments here cannot give such good results. Experiments made with a view to improvement on the lines suggested have

A PROPERABLE INSIGHT, build, beard of, is carried on among the fill for Connectivat (Ser. Am.). It as the manufacture or butch oil, which is used largely for confectionery, and gives a refect wintegreen flavoir. There are eight noils in the State—the first built only ten years ago. Burch brush, without longage, and notiver 24 inches in diameter, from the black, mountain or reager burch (not the yellow or white), is chopped up and holled with water to inside. The team, passing through an iron pipe near the top, is condensed in a coil immersed in rounning water, and drops into a glass jur. The oil is much heavier than water, and in the crude state is of copper has the mills work only from October to Apul A good deal of adulterated birch oil is used in tanning leather to imitate Kusua leather.

WE have just received the Report for 1890 of the Botanical Exchange Club of the British Isles There are about fifty members, and a list of the plants that are wanted is sent out every spring. The Secretary is Mr Charles Bailey, Ashfield College Road, Whalley Range, Manchester The distributor for last year was the Rev. E T Linton, one of our most pains taking British botanists, and the Report is edited by him number of specimens received was 4100, from twenty six con tributors. The most interesting novelty of the year is an Arenaria found at the head of Ribblesdale, in Yorkshire, which is nearly allied to, but not quite identical with, 4 nor vegica, known only within the British area in the Shetland Islands and Orkney, and I ciliata, known only in County Sligo Mr. Linton treats it as I rothica. Fries , but that plant is an annual, whilst the Ribblesdale plant is a perennial It is, in fact, a form about half way between normerua and cothica Out of thirty eight pages of the Report, eleven are occupied by Rubi. A new general working up of the British Rubi is much wanted, and it is evident the different referees to whom the specimens have been sent do not use some of the names with the same application or range of significance. What beginners want are good typical specimens of the most distinct forms To give their the intermediate connecting links before they know thoroughly the typical sub species only bewilders them roses the difficulty is that it is often impossible to determine a given plant positively without seeing it in three singes-flower, young fruit, and mature fruit-and nearly all the specimens sent to the Club arrive in a single stage. The above remark applies to R mollis and tomentosa, concerning which there are eleven paragraphs in the Report, none of which tend to any real en lightenment. To Hieracia the same remark applies as to Rubi , but Mr. F A. Hanbury's elaborate monograph, now fairly started off, will put this right. Three other sets of plants are at present receiving much attention from the members, se, hybrid willows, hybrid Epilobis, and Potamogetons At the end of the Report there is a long list of new county records

THE additions to the Zoological Society's Gardens during the past week include a Brown Capuchin (Cebus fatuellus 9) from Guiana, presented by Miss Phyllis Duncan, a Red-bellied Squirrel (Scene us variegatus) from Trinidad, a Golden Agouti (Dasymocia aguis) from Guiana, a West Indian Agouti (Dasy procta cristata) from the West Indies, two Violet Tanagers (Euphonia violacca) from Brazil, presented by Mr. R J. L. Guppy, C.M.Z S ; a Common Otter (Lutra vulgaris), British, presented by Mr D E. Cardinall , a Marbled Polecat (Putorins sar maticus) from Quettah, presented by Colonel C Shepherd . a Vuloine Soulrrel (Sciurus vulpinus) from North America. presented by Miss Pickford , seven Lemmings (Myodes lemmus) from Norway, presented by Mr. T. T. Somerville, two Sparrow-Hawks (Accepter misus), British, presented by Mr. Digby F. W. Nicholl, F.Z S.; a Grey Parrot (Psittacus erithacus) from West Africa, presented by Mrs. Hale; a Golden Eagle (Aquila

chymacsis), European, presented by Capisan Tsylor; a Common Chameleon (Chameleon vilcas) (from North Africa, a. Dwaf Chameleon (Chameleon Vilcas) (from North Africa, presented by Capisan Wood, is to Common Chameleons (Chameleon vilcas) (from North Africa, presented by Mr. E. Palmer; as Egyptian Ichneumon (Infrastes twin winse) from Span, a Blackheaded Calque (Casto melanocybula) from Denesara, deposited; a Vak (Irohafong virmunus), hom un the Gardens

OUR ASTRONOMICAL COLUMN

PERIODIC VARATIONS IN THE LATTIUDE OF SOLAR PROMINENCE—From a paper by 176 Rice), in Comptate conduct for August 3, it appears that the meen lantitude of solar results for August 3, it appears that the meen lantitude of solar prominences varies periodically in the same way as that of sports, and the same of the solar prominences and the same way as that of sports, and dimension of solar prominences have been made at Palermo an 2207 slays, with the same refractor and spectroscope. In this period food prominences have been observed, having a height period to or greater than 30° Neglecting a few irregularities, excitivity prominences occur neasest the sam's equator, the mean intuited for both hemispheres in the second vera refer the last maximum being 37° 5. There is then a rapid general increase in the latitude of most frequent occurract, upon other frequent courtered, upon the same size of the s

of spins according to Prof. Sporer's observations, and three found from the profit of the Currefound from the profit of the Currefound from the parallel to each other, and are separated by an
approximately equal number of degrees at all points: It is
worthy of remark that the photographs of the solar corona
recently investigated by Prof. Biggiove exhibit a movement in
littude which is most probably connected with the latitude,
variations of sina-posts and prominences:

PHOTOSCHAPHY OF SOLAR PROMINENES AND THEE SECTEMA — In the American Journal of Sizence for August, and Attenuan has Medicated as Son 505, Prof. C. If East piece of Sizence is the Sizence of Sizence in the S

liarly useful as backgrounds for the bright prominence lines, and

liarly useful as backgrounds for the bright promuences lines, and allows the use of a wide allo. Working with a tangential alli, Frof Hale has obtained excellent photographs of revertals of Hand K. The former line is found to be double, the compation being about 1 y sent-metres less refrangible, and position of the properties of the be made while the exposure to the H and K region is going on.

Certainly, if Prof. Hale should be able to do for invisible proobservable, our knowledge of the relation between the two classes of phenomena and their connection with sun spots would be considerably extended

The Congress of Hygiene . . .

PAGE

393

THURSDAY, AUGUST 27, 1891.

THE CONGRESS OF HYGIENE.

TE continue this week our account of the work done at this Congress. It will be clear that with the space at our disposal it is only possible to refer to few among the many subjects discussed Among these we have selected those which have the closest connection with those researches now attracting special attention.

In regard to the subject of tuberculosis it was certainly a happy inspiration of the officials of the Bacteriological (II.) and Comparative Pathological (III) Sections of the International Congress of Hygiene and Demography, to call a joint meeting in order that a full discussion of the scientific and practical bearings of the questions relating to "the transmission of tuberculosis from animals to man by means of flesh and milk derived from tuberculous animals" might be possible, and it was also fortunate, as far as its success was concerned, that the discussion was opened by Profs Burdon Sanderson and Bang, each of whom in his own sphere is singularly well fitted to lay before the members of the Sections what is at present known in the medical and veterinary scientific worlds concerning this important subject. Prof Sanderson's early researches on tuberculosis have opened up the way for much of our present knowledge on the subsect, in addition to which he has watched the question most carefully through its various stages of evolution, whilst Prof. Bang, by his numerous practical observations and scientific experiments, has given a completeness to our knowledge which has not been attained as the outcome of | teids, that it is rendered very much less digestible; and the work of any other observer

The discussion on this question afforded another instance of the intimate connection between the purest research and the most practical affairs of every-day life.

Thus from the tenor of the discussion it may be gathered that the danger arising from the ingestion of tuberculous milk and meat has probably been exaggerated.

Some of those who took part in the discussion, for example, seemed to doubt whether primary tuberculosis of the alimentary canal-re. tuberculosis confined to this region and evidently the result of infection through the mucous membrane -was ever met with in adults, and even whether it was of very frequent occurrence in the child . whilst other speakers were able to instance out of their own experience certain cases of the former and many of the latter, strongly accentuating the fact that such primary disease of the intestinal canal does exist. Then, again, one speaker was convinced that Koch's bacillus had little or nothing to do with the production of tubercular disease . but the contention had been met by so many accurate observations and experiments that he may be said to have been ruled out of court, though it was on all hands agreed that the bacillus might be helped in its work by various predisposing causes, many of which were brought into full prominence during the discussion. It was also accepted that the tuberculosis of cattle is similar, as re-

gards its causal agent, to the tuberculous of the human subject, and that the disease is merely apparently modified owing to the different conditions, and perhaps delicate tissue modifications, offered by the different hosts of the parasitic bacillus; and from the most careful and detailed experiments, of which a large number were described. there seems to be no question that tuberculosis is communicable from animals to man, and certainly there appears to be none that it is communicable in the opposite direction.

There was a general expression of opinion as the outcome of the discussion that legislation of some kind or other is necessary, but, as pointed out by Burdon Sanderson, if laws were made to morrow there is absolutely no staff of inpectors capable of giving effect to any that might be drafted It is probable that this will draw attention, first, to the necessity for conferring powers of inspection of dairy and store cattle on some central authority; and second, to the necessity there is that our veterinary surgeons should undergo a thorough scientific and practical training, such as would fit them to fill the posts from which unfortunately they are necessarily now in many instances excluded

When all is said and done, it appears that the danger arising from the consumption of tuberculous meat is far less serious than that involved in the consumption of milk from tuberculous animals, as meat, if thoroughly cooked, appears to be perfectly innocuous, the tubercle bacilli being readily destroyed by heat, whilst the nutrient properties of the meat itself are little, if at all, interfered with by judicious cooking. In the case of milk, however, in which the presence of tubercle bacilli has been so often demonstrated, it has to be borne in mind that boiling so alters the constituents of the milk, especially the proits nutritive value is greatly interfered with

We now pass to the discussion

TUBERCULOSIS IN ALL ITS RELATIONS.

Prof Burdon Sanderson said the subject which he had under-taken to bring before the notice of the conjoint Sections for discussion was one of the gravest importance, for there was no disease, acute or chronic, which was so productive of human suffering or so destructive of human life. In a Concress of Hygiene the subject of tube culous could only be considered in relation to its causes, the aim of hygiene being to prevent disthose questions which relate to the dangers which are alleged to arise from the use of tuberculous food (1) Does general luberculosis in man originate from intestinal infection? (2) If it does, is it possible to guard against so fearful a danger? the purpose of avoiding useless discussion on subjects on which there each to be perfect agreement of opinion, he asked that certain fundamental propositions should be accepted as settled, such as, for example, the existence of a materies more in the form of the tubercle bacillas, its constant association with the tuberculous process, and the identity of human with bovine tubercle; and also that it be assumed that any part of the body of a tuberculous animal or any secretion of such an animal would, if it contained tubercle bacilli, be a source of danger, and would, I'll contained tuberrie uscill, no a source or stanger, and that they use of such inquid or part ought to be prohibited or on the quantum and the properties of the properties of the logical or stilogical, the others practical or admunitrative. The collogical questions might be said to relate to the three possible ways in which a human being may be infected by tubercle— namely, inheritance, pulmonary inhikation (temospheric infe-tion), and food (enteric meterion). The practical issues were—

(1) Is the risk to the individual consumer of such a nature that it can be detected and estimated?
(2) Is it of such a nature that it can be counteracted?

(3) Is the collective risk to which the community is exposed sufficient to demand the interference of the State? and

sufficient to demand the interference of the State? and (a) If it is, I how can the State Interfere with effect? (d) If it is, I how can the State Interfere with effect? (d) If it is, I how can the State Interference Interfere

chedly from the point of view of the vetermarian In 1888, M. Adiong, following out the principles enunciated by another gifted pathologist, the late M. Toussaint, that tubercle is a diverse total uniform to engineer annatumed that the time had come to act "conformant à la logique." One out of every six carcasse had been shown, he said, to be infective, when tested by administering it to test animals as food. If calculated that over one thousand persons joined in the conformation of sumption of every such carcass, and consequently that one-sixth of this number—that is, about 170 persons—must be subjected to the risk of infection for every animal sent to the shambles If this reasoning were true, if we could measure the danger to to this reasoning were true, it we could measure the danger to the human consumer by the presence of tuberculous among animals used for food irrespectively of other considerations, then M Arloing was right in his practical deduction from it that whatever interests conflict with public health they must give way It was our duty to insist on the right of science to dictate : but in doing so it was necessary to be careful not to do so until the question had been looked at from all sides and the whole evidence

had been heard. In some of these discussions it had not been sufficiently considered that the question was not whether the consumption of tuberculous meat was in itself attended with risk, but whether the presence of tuberculous diseases among ourselve, was in any the presence of tunerculous diseases among ourselves was in any way due to the fact that we occasionally eat meat which contained bacill. It was not sufficient to show that on the one hand there was a fearful mortality from tunerculous diseases, and that on the other there existed a cause to which this calamity might be attributed. It must also be shown that the effect was actually produced by the cause, in such sense that if the cause were removed we might hope that the effect would disappear

Twenty-three years ago Chauveast fed three heifers with tuberculous material from the body of a cow and obtained positive results. At that time the idea that tuberculous was a virulent disease was new M Villemin had made his great discovery, but it had not yet been accepted, and consequently Chauveau's results were severely criticized, and were the subject of much discussion, which extended over several years (1868-74), during which he repeated his abservations, effectually silenced his opponents, and determined with the greatest exactitude all the conditions which are required to insure success in the experimental pro-duction of tuberculosis by feeding. Gerlach about the same time made similar experiments in Germany which led him to advocate in the most energetic manner the restriction of the sale of tuberculous meat.

These two mittal investigations were followed by many others. In 1884, Baumgarten showed that a couple of ounces of milk to which a pure culture of tubercle bacillus had been added were sufficient to produce characteristic tuberculosis in the in-testines of a rabbit; and that the effect of such feeding was so constant that by examining the animals so fed at successive constant that by examining the animals to led at successive periods all the larges of the process could be thoroughly investi-period and the larges of the process could be thoroughly investi-lation; of a fortnight, during which no traces of infection were viable, the lymphatic follicles of the mucous membrane and the mesentence glands began to enlarge simultaneously without any change whatever in the intestinal epithelium.

It was thus shown with a precision which was not before ob-tainable that the initial phenomenon of tuberculosis was primarily a proliferation of the adenoid issue of the lymphatic system, and that the bacillus was capable of finding its way into the lym phatic system without leaving behind it any appreciable traces of its presence at the portals by which it had gained admission Since 1884 our knowledge of the subject had been still further advanced by Cornil, under whose direction two very important researches, confirming and extending Baumgarten's results, have been recently published, from which it was evident that when

the tubercle bacillus is absorbed from the intestine it follows the course of the lacteals, and that the lesions which it produces correspond closely with those which present themselves in those rare instances in which it is possible to observe the first begin-

nings of enteric tubercle in the hunan subject

Much, however, has still to be learned by the experimental muen, however, has still to be learned by the experimental method—information which could only be guized by observation on animals. According to those who regard tuberculesis as ancessarily a disease, believe institution to organize the body is contaminated, all meat derived from the body of a tuberculova named another to be contaminated. part of the body is contaminated, all mext derived from the body of a tuberculous animal ought to be condemned, whether it appears healthy or not, for they argue that in every such animal, however localized the disease may be, bacilli circulate in the blood, and are so universally distributed

Prof Sanderson believed that this was not true, and that we are not entitled to assume that the flesh of every tuberculous animal is infectious unless it be proved to be so. As against the animal is infectious unless it be proved to be so. probability of its being so, it must be noted that the tubercu-losis of cattle, although the product of the same bacillus as the tuberculosis of man, is a disease of comparatively slow progress It localizes itself in structures which are not essential to life, and It localizes item in structures which are not essential to the, and nutrition might be so little interfored with that the animal could be readily fattened for the market. There was no doubt that the fish of such animals might be to all appearances in good condition, and might be offered for sale as meat of prime quality, and as yet we have no evidence that it is infective.

Turning from the source of infection to its effects, from the bacillus to its field of disease and death-producing action, I'rof Sanderson said that tuberculous diseases contribute something like 14 per cent to the total of deaths from all causes, and that during childhood, as distinguished from adult life on the one hand and from infancy on the other, tuberculous mortality/scarcely amounts to a quarter of this percentage, whereas in infancy it only falls a little short of it, and in early adult life. it very far exceeds it

There was evidence that under certain conditions the virus of tubercle was absorbed by the lymphatic system from the small intestine in man, and that when this happens it may give rise to lesions of the same nature as those produced in animals by the injection of liquids in which bacilli are suspended—that is, to disease of the intestinal mucous membrane, although very cou-mon, never occurred in the adult and very rarely in infancy as a primary disease. In the adult it might occur as an ulterior consequence of pulmonary consumption, the way in which it occurred being very evident. In the advanced stages of that disease muco-pursient inpul was discharged in quantity from might infect the mucous membrane along which it passed so that it is easy to distinguish bronch which lead from vomme by the tuberculous nodules with which they are more or less best. In advanced philine the putture is to shundant that a certain proportion of its from time by time study. For closely offer the proportion of the free constitution of the constitution o primary disease In the adult it might occur as an ulterior conpasses too rapidly, while in the latter the mucous membrane is effectually protected by the gastro junce, which, although mea-able of devitaling the bacilits of tubercle, areast its develo-ment. In the alkaline contents of the small intestine a condition more favourable to its development was found, and from there it was absorbed, just as any other particle of similar size might be, by the lymphatic follicles. Tuberculous disease of the small intestine in the adult thus occurred. It was always a

secondary result of pulmonary phthsis.

In childhood the case is different. Tuberculosis does not begin to assert itself as a cause of death until the third month of extra uterine life, but after this there was good reason for sup posing that the bacillus plays an important part as a cause of mortality.

mortality.

mortality of the plant is question of how latent tuberculous of the papather system or of bose oreginates, as how the hacillity which produce them are introduced into the blood aream was one of great interest. Prof. Sanderon confessed it to the his belief that m a certain proportion of cases the cryptogenetic proportion of the proposition of and that the mucous membrane of the intestine is tuberculous in a still smaller proportion—less than a quarter. In many of these cases the mucous membrane was no doubt affected subsequently on tuberculous disease of the lungs, but in the remainder the disease seemed to be primary — If it could be proved that such cases were primary, the fact would afford clearer evidence than any we now possess of the enteric origin of tuberculosis.

than any we now possess of the esteric origin of tuberculous.

In the absence of such proof, human pathology had very little
indeed to say in favour of the bellef that human tuberculous
could owe its origin to the convumption of tuherculous food, and
even if it were proved that the absorbeats afforded a channel of
entry for the tuberculous versu in children it would have little

significance as regards the consumption of mest.
The author beld, therefore, that we are not as yet in a position to demand the interference of the State on the ground that the community actually suffers from the consumption of ubbrealous meat, the evidence that it is so being too weak to be insisted on, but he manitumed that the consumption of subervicelous meat was attended with some danger, and that on that ground its was attended with to be prevented by the State and avoided by the Individual.

and regards the administrative question, he held that if we held, to-morrow, a law forbidding the sale of any mest containing the bacillas of tubercle, it could not be carried out unless those charged with its administration were able to distinguish such charged with its administration were able to distinguish such the law would depend on the question whether the art of discriminating between infecting and non-infecting mest had attained to such perfection as to enable an adequately transcell discriminating between infecting and non-infecting mest had attained to such perfection as to enable an adequately transcell interested for contamption should be withpeted to inspection, interested for contamption should be withpeted to inspection, interested for contamption should be withpeted to inspection, adequate compensation, but all this would be of no use unless the principles on which the discrimination of infecting from non-infecting mean in to be founded could be laid down, and the the principle of the principle of the discrimination of the contamp of the discrimination of the contamp of the discrimination of the discrimination of the contamp of the discrimination of the discrimination of the contamp of the discrimination of the discri

but by practical skill.

Dr Sanderson then submitted the following propositions to the meeting of the combined Sections —

(1) That tuberculous must be added to the list of disease regarded by the law at contigons. There is no sufficient reason for supposing that in the human adult the introduction of the bacilli of tuberclib by enteric absorption is the efficient cause of the particle of the control interpolar tuberculous diseases of the lymphatic system are probably due to the penetration of bacilli into the organism from the missine; but the evidence which we at present possess on his subject is not sufficiently precise or extended to server as tuberculous in a lifancy is a subject which trigently requires investigation.

investigation.

(a) It has been proved that the ingestion of any material which contains the bacilli of tubercle is a source of risk to the consumer, but the conditions which limit this risk are insuffi-

ciently known. It would, therefore, be unjust to enforce the destruction of any specimen of meat apparently healthy, even though it were known to be derived from a tuberculous animal, excepting on evidence given as regards the particular case that it would be infecting if administered to test animals.

trough it were known to no enrived from a tunerculous animas, accepting on evidence given as regards the particular case that excepting on evidence given as regards the particular case that (3) As regards the duty of the State in relation to the prevention of tunberculous, what is immediately required in that an efficient system of skilled inspection should be created. Thus it desirable, not merely as a first step toward, a prevention of the sale and consumption of tunberculous meat, but as an indispersable means of acquiring better information than now exist. To be of use it must be confused by men of technical skill wit forth. It must be confused by men of technical skill wat forth.

sating under scientisic guidance
"In conclusion," said Dr Sanderson, "I would beg you
to notice that I have limited myself to the question of the
consumption of sense. Although I have purposely left the
source of the sense of the sense of the sense of the
minds bear upon it. We have seen it to be exceedingly
probable that about 40 per cert of the children that die
in hospital, die tuberculous I have alrealy expressed my
stylependent on causes which have operated before hirth.
Some are probably infected by inhalation of the tubercle bacilise
from the aimosphere, notwithstanding that pathology affords so
satisfactory evidence, I cannot result the conviction that the consamption of unboided mild during the years which follow weaning
must have its share in bringing about the fatal previdence of
sell that, whatever course may be taken as regard in users, I can
jonn hearnily with those who tlank that the sale of contaminated
fills of the sell o

Dr Bang, Lecturer in the Royal Veternary College, Copenbagen, in a paper on "The Alleged Danger of consuming the apparently Healthy Meat and Milk of Tuberculous Animals," stated that the great majority of investigators are agreed that the essential source of tuberculous is man is found in man himself, but almost all admit that he may contract the disease through the ingestion of milk derived from animals affected with tuberculous.

It is always agreed that such a danger exists, but as to the extent of the danger there is little unanimity.

Of course, it might be said that there would be no danger if

Of course, it might be said that there would be no danger if the use of meat and milk from the tuberculous animals were entirely interdicted, but it must not be quoted that the application of such a stringent measure would, existed enforcing loss where the fivessee has a very wide distribution amongst bowne namials. He looked upon the general application of the French regulations as out of the question, at least for the present, which such a course appeared on the whole to be unnecessary. As regards milk, the question of prophylaxs was comparatively enabled that the such as the contraction of the property of the contraction of the property of the contraction of the property of the present such that a should never be employed. How can we protect ourselves against the products of milk?

The experiments made by Galter, the saturb, Hum, and other.

The experiments made by Galifer, the author, Hum, and otherhave proved that the various products derived from milk, batter, cream cheese, cheese, and batter milk may all contain tubered period of from Goutteen to thirty days. It was true the majority of these bacills may be separated from milk if the cream berevoed by means of a centringful enabline, as a generally done money of the control of the cream between the control of the control of the wind that the control of the cream between the control of the control money of the control of the conbefore charming to a temperature high enough to kill the tuberels of the control of the control of the control of from 60° varue, so far as to render t incapable of setting up infection of the alumentary canal. This method is coming more and more into use in Demanri, as by it several other vources of infection in the butter are also neutralized. As however, many popular to the control of th

that when the udder is affected with tuberculosis there are usually numerous bacilli in the milk, which is consequently exusually numerous Bacilli in the mile, which is consequently ex-remely dangerous. But he also finds that manmary toberous abundance of Copenhagen, for example, it has been found that only in 1 per cent. of tuberculous cattle was there disease of the udder. From twenty-eight tuberculous cows, in which, how-ever, there was no disease of the udder, the milk was supected into forty sight rabbits, and in only two was there any positive result. He then inoculated forty guinea pigs with milk from twenty-one tuberculous cows, in this case with four positive results. Recently he had carried on a new series of experiments with the milk from fourteen extremely philipsical cows In this series the milk was virulent in three cases, so that from saxiy three tuberculous cows the milk contained virulent tubercle bacilli in nine cases only. All these cows were affected in a very high degree, and it is probable that in some at any rate the uider was affected, though this could not be demonstrated in the living animal, as it was in three out of the four cases of the second series. Others were affected with miliary tuberculosis in second series. Others were affected with military tuberculosis in the different organ, a condition which one rarely finds in an animal that is still giving milk, and in one case the sapramammary lymphatic glands were affected with tuberculosis, although no lesions in the udder itself could be demonstrated. In several of the positive cases the number of bacilli in the milk must have been very small, as one only of the two guinea-pigs experimented upon succumbed to the disease, this happen-ing in three instances.

It should be added that the quantity of milk injected in the later series was larger than in the earlier series. In the two later screek was larger than in the earlier series. In the two first series 1 of 3 c.c. was injected, in the third 5 to 10 c.c. He maintained that, although in many cases the milk from phthiascal cows is not virulent when the mammary gland is unaffected, it is in a certain proportion of cases, and should always be looked upon with susplicion, and that it is abolutely necessary to take prophylactic measures against the use of such milk, although the danger should no doubt not be exaggerated.

the danger should no doubt not be exaggerated.

Mat.—The his tied very seldom contains any ubserile. NeverMat.—The his tied very seldom contains any ubserile. Nevermancle jusce may contain tubercie bacille, but such cases, according to the observations of Charaves, of Ariolog, Feoth, Galtier,
Nocard, Kastner, and others, are absolutely in a minority

anunals moculated.

animals inconnated.

M. Nocard's experiments in this connection are very interesting. He found that when a culture very rich in bacilli was injected into the veni of the ear of a rabbit, the muscle juice of the animal was virulent only when it was killed within five days after the incoulation, from which he argued that the bacilli carried by the vessels to the muscles only preserve their vitality for five days. If to this experimental result be added the ob for nive days. It to this experimental result be added the ob-servation that tubercle is very seldom developed in the mucles, servation that tubercle is very seldom developed in the mucles, loss, it must be concluded that muscular tissue is a soil so in-favourable for the growth of tubercle bacilli, then, that can be found in the field of tuberclous saminals as layers extremely found in the field of tuberclous saminals as layers extremely limited. It is of course true, as M. Arloing has objected to M Nocard's conclusions, that the circulatory system of a tuber-culous animal can continually receive into it fresh bacilli, and therefore until within only a few minutes before the animal is slaughtered. But, on the other hand, it must not be forgotten that it is only in the case of the development of an acute miliary that it is only in the case of the development of an acute minary unbercalous that one can suppose that the number of bacilit inunbercalous that one can suppose that the number of bacilit inunbercalous the case of the

unimportant part in the result obtained.

Prof. Bang stated that he had recently completed a series of experiments on the virulence of the blood of cows in an advanced stage of tuberculosis. From twenty tuberculous cows he moralated thirty-eight rabbits and two guinea pigs with defibrinated blood, injecting from 10 to 18 c.c. (in four cases only 5 to 9 c c.). mjecting from 10 to 18 c.c. (in foor cases only 5 to 9 c.c.). In eighteen cases the results were negative, in two positive, and one of these in which the lesson was small was one of two rabbits in-jected with blood from the same cow. The cow that supplied the blood with which the other positive result was obtained had developed acute miliary tuberculosas after an injection of tuberculon. Three weeks previously blood from the same cow had given negative results. Even amongst those cases in which the results were negative there were several cases of acute miliary

He concluded from the foregoing that the seizure of all inberrre concused from the foregoing that the setzure of all ther-citious animals is too stringeria measure. So long as the tuberculous is strictly localized, the meat is not a source of danger, where the malady is generalized, the consumption of the meat may be dangerous, allhough it is not always so. The eating of uncoded meat should be discouraged, but the best means of avoiding danger to the health of man is to take all possible measures for preventing the propagation of tuberculosis amongst our domestic animals.

Prof Ariong, of Lyons, contended that the question of transmissibility of tubercelosis from animals to man was one of vigerest importance, but he adminted that the daggards private was represent programs, but he demonstrated that the daggards private was great, and he thought could scarcely be esaggerated. Moreover, he held dvery strongly that, except under certain special circumstances, the total condemnation of between the was necessary, and on grounds of public health he dissented entirely from Dr. Bang's position. The fest of all tubercelous sundamins should be suspected as

dangerous to health, the more so as mest was very often indangerous to heatin, the more so as mest was very outen in-sufficiently cooked, the haddlip resent under these conditions remaining pathogenic. From satistics he had gathered, he felt no doubt on this subject, and although it might be possible, by first carefully cooking under public supervision, to allow to fish from animals in which the tuberculous was localized to be sold, he still maintained his position that total confiscation of the sour, he still maintained his position that total connection of tuberculous meat was the safest method to be adopted. It was necessary, however, that in the first in-tance we should have a system of strict inspection, not only in our large towns, but also in all the smaller centres of population.

A paper was then given by Prof. M'Fadyean (Edinburgh) and Dr. Woodhead (London), on the transmission of tuberculosis from animals to man, by means of flesh and milk derived from tuberculous animals They maintained that the evidence as to the transmission through the flesh or milk of tuberculous animals was transmission tarongo the near or mile of tuberculous animals was very conflicting, apparently in great part because the methods used were different, and the conditions were not uniform. They had attempted to follow the line of infection of tuberculous in a number of children, and had found that in 127 cases analyzed number of children, ann nat sound inax in 127 users manayers unberted of the intestine was present in 43, 124 of these cases occurring between one and five and a half years; tuberted of the meenteric gland was found in 100 cases, or in nearly 79 per cent of the whole, here, again, 62 of these occurring between one and five and a half years, and of it cases in which the one and a read a native years, and of 14 cases in which the mesentence glands were primarily affected—i.e. no trace of tubercle could be found in any other part of the body—were referred to the same period. It was noticeable that of these foo cases only 20 were diagnosed during life as suffering from about must lubercle. From all that could be learned from these cases (and reference could be made to a large number of other sets of statistics practically proving the same point), it was evident that intestinal and mesenteric tubercle are inost frequently met with in children during the period after they are weaned, at which time cow's milk has been substituted for mother's milk. pant of entrance appeared in these cases to be by the intestine. They had come to the conclusion that in some cases at least the tubercle bacilli had passed from the intestine into the mesenteric glands without leaving any trace of lesion to indicate their point of entrance. There could now be no doubt that tubercle health of enrance. There could now be no doubt that tubercle baselin were sometimes present at the male from tuberculous catie, on the could be a supported to the male from tuberculous catie, or bins from the could be considered to colonia such bandle embedded in the epitheliam of the milk duct, or lying free in the ducts after the death of the animal They concluded that wherever the presence of a tuberculous the colonial could be considered that wherever the presence of a tuberculous behinder that the considered that wherever the presence of a tuberculous behinder to the considered that where the considered that where the considered that the co

poor classes, where the standard of health is exceedingly low and the hability to catarrhal conditions very great. From a series of incottalions with tuberculous udder, and with milk from tuberculous udders, it out of 10, or over 70 per cent, had given possitive results; with non tubercular udders, and with nulk from otherwise tuberculous cows, only 2 cases out of 13, or milk from otherwise tubercolous cows, only 2 cases out of 13, or a lattle under to per cent, gase positive result. Where the failure to produce tubercolous occurred in the first series, the case of the control of the played an important part in determining the severity and rapidity of the course of the disease, and they stated that their experience accorded with that of other observers, that inoculainto the perstoneal cavity is much more certain than noculation into the subcutaneous listue, especially where the number of bacilli introduced is comparatively small. They are also led to believe, from a number of feeding experiments, that the production of tuberculosis through the introduction of bacilli into the allmentary canal is of still less frequent occurrence into the ailmentary canal is of titll less frequent occurrence than when inoculation is made into the connective tissue. As regards the possibility of the flesh of tuberculous animals setting up tuberculosis, (a) when introduced an mazis, (b) when expressed juice only was exhibited, their experiments went to prove that the juice only did not in most cases contain a sufficient number the juice only did not in most cases contain a sufficient number of bacilit to set up tubertele, even when noncolated most small redents, but from the fact that they have observed tubercular masses in the muncles of the buttoes for furnerculous cattle, it must be accepted that tubercle bacilit may sometimes, though perhaps retry, be present in considerable numbers in this position. Of three cows Mangaleted in one day at one stangther house, when contains the most of these three variables when the contained in new contained to the contained to most of these three variables contained to the conta definant tubercle was found in the muscles of the battock of two naminals; in one of these there was tubercellosis in every organ and part of the body; in the other there were only a few nodies and no stone of the glainst, there was certainly no modiles and not stone of the glainst, there was certainly no manifested. They concluded that there was great necessity for a thorough inspection of both dury cattle and of ammals that were slaughtered for food purposes, but it might be accepted that the danger of contracting tubercle from milk was greater than proportion of cattle affected with tubercellous did there seem to be any danger to be anticipated from the ingestion of the flesh. proportion of cattle affected with tuberculosis did there seem to be any danger to be anticipated from the ingestion of the flesh. In the main they agreed with Prof. Burdon Sanderson and Dr. Bang that there was not yet sufficient evidence on which to decide that the total seizure of meat from tuberculous animals should be resorted to.

Prof. Hamilton, of Aberdeen, said that there were two principal channels of infection, (1) the gastro-intestinal tract, (2) the lungs, but in addition to these whad what ingit he spoken of as localized tubercle, which seemed to be shut off entirely from all communication with the external world (1) In the body the sflection might take place by the sir channels, as in the case an communication with the external words (1) is the body of the color present of the color of th

positive results obtained in which all possible sources of failure could be eliminated. Whilst saving this, he must admit that in the case of children tuberculous material, whether in meat the case of children tuberculous materias, whether as mean or milk, would always prove a very important source of danger. He would draw attention to the disease as it occurred

danger he would draw attention to the disease as it occurred no cuts, on which animals he had made many experiments. Dr. Hume, of Bradford, was glad to find that our foreign frends, who are not hampered as we are in making experiments, agree with us in the main. He thought that we were likely to run wild on the subject of the total sleziare of tubercular meat, run wild on the subject of the total seture of tubercular mear, and he would point out that in no county does a total serure law exist such as it is proposed to adopt here in England. In England he would point out that the inspection is worse than in any other country. He referred to Prof. Lingard's experiments any other country He referred to Prof Lingard's experiments given in an official report, which, he pointed out, spoke only of tubercle being transmitted by caseous material, and not by meat from a tuberculous cow, as was usually assumed We had the authority of Koch himself, said Dr. Hime, that there is danger only when tubercular material itself is ingested. Infection by milk he looked upon as proved, but he would also insist very strongly that the majority of infection in cases of phthisis was directly between man and man, and it was far more important directly between man and man, and it was far more important that we should eliminate possible sources of contagion between that we should eliminate possibilities of infection from animals to man. Dr. Barlow (London), speaking from a clinical point of view, was scarcely able to indone the results of experimental researches, and he manimated that as regards suberculous in

children we must for the present keep our minds open children we must for the present keep our 'minds open. There was no doubt that the post morient in children's hospitals gave evidence of the curronous frequency of toberculosis, but the evidence of the curronous frequency of toberculosis, but the contract of the curron of the curro danger

of. Perroncito, of Turin, referred to a number of experiments Prol. Perroncies, of 1 urns, reterred to a number of experiments that he had carried out with meat, milk, and the products of the latter, and then pointed out that spontaneous tubercle very rarely occurred in the pig, though it might frequently be met with as the result of infection. The same might be said of sheep Here, also, it might occur, though rarely, as the result of direct

Prof Burdon Sanderson, in reply, said he was pleased to find Prol Burdon Sanderson, in reply, said he was pleased to find that the difference of opinion among to amany suffordite was so slight. If was evident that all were agreed that impedies no sa regard the difficulty of diagnosis. He way glid to find that as regard the difficulty of diagnosis. He way glid to find that for total science, except under very well-defined conditions, he had so fir given way as to acknowledge that such meat might after careful conchine by entailed under special restorations. In order nad so far given way as to acknowledge that such meat might after careful cooking be retailed under special restrictions. In order that something definite might come out of this discussion, he proposed that it be minuted that "the etiology of tubercular disease of early infancy (between three mouths and five years)" be referred for discussion at the next Congress

This was seconded by Dr. Septimus Gibbon, and was carried

unanimously

The President said that he had been greatly interested in the discussion, and he hoped that much good should arise therefrom. He was glad to find that there were some animals, such as the

He was glad to find that there were some animals, such as these pand pig, in which pontainous tuberice was never met with, and he hoped that we might eat these in asfery Supercelly appeared to have a great minimum; as regards tuberich, subject of tuberculous.

Dr. Metschnilforf and Dr. Roux, gave a joint paper on the changes that took place in the issues around tuberich bestellin; twa reads by the former, who illustrated his remarks by means of drawings on the black-board, and by microscopic specimes of drawings on the former, who illustrated his remarks by means of drawings on the black-board, and by microscopic speciments. the tubercle bacillus. He could not understand the comparative immunity from tubercle enjoyed by the pericavilim and the stomach. Prof. Nocard, of Paras, did not think that sufficient proof bad as yet been accumulated that ingestion of tubercalous meat. The process of recovery was indicated by the presented coaled give rise to tubercalous in any high proportion of cases; the greater number of supermental cases had give no contentify enjoy of had an indicated by the presence results, and she hold, to convince himself, require to see more justices the supermental cases had give as process of calculations.

Prof. Ehrlich proceeded to give Koch's present views re-garding tuberculin. He said that the results that bub eva-lation is a superior of the professional professional professional pro-lated to the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of the control of the control of the con-trol of the control of t long as possible the specific excitation of the tissues, and not to do away with this, as was the case where large doses were used. Wherever successful results had been obtained they had all been by the use of repeated minute doses of tubercuhn, which all been by the use of repeated minute doses of tubercum, which were only very gradually increased in strength, and it should be specially noted that the pathological signs found as the result of the action of tuberculin were always produced by large doses Prof. Cornil, Dr. Bardach, Dr. Fonnnck, and Prof. Hueppe were agreed that tuberculin was an heroic and dangerous semedy

were sured that tuberculin was an heroc and dangerous remedy about which we as yet knew little, and which was therefore to be looked upon as still being experimented with Italso seemed to be the general opinion that where it was in use there existed a danger of acting up generalization of a tuberculosis that had hitherto been localized

hitherto been localized — The Hard Revented Park William (1994) and the Hard Revented Park Hard Revented Par remedial effect.

The President, summing up, hoped that in time we should all be able to obtain the wonderfully satisfactory results that had been so fully described by Prof. Ehrlich on Dr. Koch's behalf.

NO. 1139, VOL. 441

THE BRITISH ASSOCIATION

THE Cardiff meeting, if it was not made remark-1 able by any incident of very special importance, was, upon the whole, successful. Several of the addresses delivered by the Presidents of Sections were of exceptional interest, but some were very long, and

we shall not be able to print all of them.

At the first meeting of the General Committee, held on Wednesday, August 19, the report of the Council for 1890-91 was read by Sir Douglas Calton. Dr Gladstone moved a vote of thanks to Prof. Williamson for his long and valuable services as general treasurer, paying a tribute to the manner in which that gentleman had fulfilled his duties. Sir Douglas Galton seconded, and transied nis quues. Sir Douglas Galton seconded, and the resolution was cordially agreed to. Mr. Vernon Harcourt moved, and Sir J Douglass seconded, the appointment of Prof. Arthur Rucker as general treasurer. This motion was also agreed to. At the meeting of the General Committee on Monday, a deputation from Nottingham was introduced The Association was strom rottingnam was introduced the Association was invited by the Mayor and town authorities to visit Nottingham in 1893. It was stated that it was twenty-five years since the Association had visited Nottingham. The invitation was accepted on the motion of Mr Prece It was also unanimously agreed, on the motion of Canon Tristram, to elect Sir A. Geikie as President of the Association, which meets at Edinburgh next year The Association, which meets at Lendungn leav, Year. I he Lord Provost of Edinburgh, the Marquis of Lothan, the Earl of Rosebery, Lord Kingsburgh, Principal Sir William Mur, Prof. Sir Douglas Maclagan, Sir William Turner, Prof. Tait, and Prof. Crum Brown were elected Vice-Presidents for the Edinburgh meeting. Prof. G. F. rresucents for the Edinburgh meeting. Prof G. F. Armstrong, Principal F. Grant Ogilvie, and Mr John Harrison were elected Local Secretaries for the meeting at Edinburgh, and Mr. A. Gillies Smith Local Treasurer A deputation from Edinburgh also attended with reference to the fixing of a date for the Edinburgh meeting. It was stated on behalf of the Town Council that September 28 was favoured as the opening date of the meeting, though August 3 and September 21 were also mentioned as alternative dates. A motion was made to fix August 3, while an amendment was moved for September 12. but as only thuteen voted for the amendment, the original motion was agreed to-that is, the Association will meet at Edinburgh next year on August 3 The general officers were re-elected, and the following gentlegeneral officers were re-elected, and the following gentlemen were elected Members of Council for the ensuing year — Dr W Anderson, Prof Ayrton, Sir B Baker, Hr H W Bates, Prof Darwin, Sir J, N. Douglass, Prof. Edgeworth, Dr J Evans, Prof Frugerald, Sir Archbald Geitie, Mr R T Glaebrook, Profs J W, Judd, Livening, Lodige, Mr W H. Preece, Profs W. Kamsay, Remold, Roberts-Austen, Schafer, Schuster, Sidgwelk, Mr. G. J. Symons, Profs T E. Thorpe, Marshall Ward, Mr C. J. Whitaker, Dr H. Woodward. The following impressions have been recorded by a correspondent :-

CARDIFF, Tuesday Evening.

One of the most prominent features of the Cardiff meeting has undoubtedly been the prevailing bad weather Rain and cold have had their usual depressing results, and may to some extent account for the disappointment which exists among many of those in attendance. The Local Committee have done their best to render the meeting a social success, but the entertainments by the Municipality and the citizens of Cardiff have been of a somewhat restricted character. Notwithhave been of a somewhar restricted character. Notwith-standing, the uppromising state of the weather, the ex-cursions on Saturday and Sunday were largely taken ad-vantage of, and the recoption given by Lord Windsor on the latter day was specially appreciated. The total attendance has been about 1 con, within 200 five Leeds mention, while the amount of money. Sunday the the set is within a few pounds of lany quan. Naturally there has

been considerable talk with reference to the address of the President of Section A, and opinion is divided as to the propriety of introducing the metaphysical into a Section which has emphatically to do with the "solid ground of Nature" On the other hand, Prof Lodge's experiment to test whether the ether is disturbed in the presence of a rapidly-moving body has excited the

greatest interest and admiration.

The soirées at the present meeting can hardly be compared in attractiveness and brilliancy with those held last year in Leeds. Wealthy and populous as Cardiff is, she has not command, apparently, of the scientific and artistic collections which are so creditable to the intelligence and taste of the dingy Yorkshire city. However, the dance taste of the dingy rorsanice city into which to-night's conversations developed evidently conversations of shortcomings. The lectures atoned for a multitude of shortcomings. The lectures have been fairly well attended, Prof. Rucker's beautiful experiments evidently fascinating his audience, in spite of a serious hitch caused by the failure of a steam-engine to do its duty when called upon The discussion, in Section D, as to the relations between animal and plant life was well sustained, and it is a pity that arrangements had not been made to have it fully reported This can be done at very small cost, and the publication of detailed reports of such discussions could not but greatly increase the good they are calculated to do. There is a general belief that inter-Sectional discussions would be of immense advantage in showing the intimate relations which exist between the different branches of science, and in stimulating research in profitable directions. It is probable that several such discussions may be arranged for the next meeting

As usual, Section E had its sensation. A very large audience attended to hear Mrs. French Sheldon describe her journey to Lake Chala, at the base of Kilimanjaro Mrs Sheldon was evidently suffering greatly from her serious accident, and although her address was somewhat disjointed, it contained a good deal of fresh information, especially on the natives, which male travellers have hitherto overlooked. Mrs. Bishop (Miss Isabella L Bird) proved equally attractive in describing her visit to the Bakhtiari country and the Karun River, and, as might have been expected, was somewhat more solid than her less-experienced fellow traveller

The Ordnance Survey formed the subject of an important discussion in Section E, and the Association as a body has resolved to do its utmost to induce Government to introduce reforms. It is fortunate that by the combined action of Sections A, E, and G, a grant of £75

has been obtained for supplying instruments for climato-logical observations in Central Africa.

There was considerable discussion at the general committee meeting vesterday as to the date of the Edinburgh meeting next year. In certain quarters the end of Sep-tember was advocated, but there can be no doubt that the great majority of the working members of the Associa-tion preferred the beginning of August, a date which will suit those connected with the Universities and will catch the citizens of Edinburgh before they leave for their holidays. It is, therefore, not surprising that August 3 has been fixed upon for the Edinburgh meeting, the President of which will be Sir Archibald Geikie Nottingham has

been selected as the place of meeting for 1893.

It is evident that the people of Cardiff are somewhat at a loss what to make of the Association and of the hundreds who are crowding the streets of the town and rushing from one Section room to another. The Sectional secretaries especially, seem to be a puzzle. In the hotel in which they are housed a commercial stock-room has been set apart for their use, with a long baize-covered table down the centre, while to discourage all tendencies to loading, they have been provided with nothing else but

hard kitchen chairs to sit upon.

Altogether, from a scientific point of view, the Cardiff meeting may be said to have come up to a fair average

SECTION D

CHEMISTRY. OPENING ADDRESS BY PROF. W. C ROBERTS AUSTEN, C.B., F R S., PRESIDENT OF THE SECTION.

The selection of Cardiff as a place of meeting of the Brush Association led to the presidency of Section B being intrusted to a metallargata. It will be well, therefore, to deal in this address mainly with considerations connected with the subject to which my life has been devoted, and I hope that it may be possible for me to show that this practical art has both pro-

gifts in return

It is an art for which in this country we have traditional love, nevertheless the modes of teaching it, and its influence on science are but imperfectly understood and appreciated Practical metallurgists are far too apt to think that improvements in their metallurgusts are far too apt to link that improvements in their processes are mainly the result of their own experience and observation, unaided by pure science. On the other hand, those who teach metallurgy often forget that for the present they have not only to give instruction in the method of conducting technique. cal operations, but have truly to educate, by teaching the chemistry of high temperatures, at which ordinary reactions are modified or even reversed, while they have further to deal are moditied or even reversed, while they have further to deal with many phenomena of much importance, which cannot, as yet, be traced to the action of elements in fixed atomic proportions, or in which 'the direct influence of the atom is only beginning to be recognized

The development of a particular art, like that of an organism,

proceeds from its internal activity, it is work which promotes proceeds from its internal activity, it is work which promotes in growth and not the external influence of the environment. It is the property of the process of the environment of the process of the pr

To know Rather consists in opening out a way Whence the unprisoned splendour may escape, I han in effecting entry for a light Supp sed to be without

If it be asked who did most in gaining the industrial treasure and in revealing the light of chemical knowledge, the answer is certainly the metallurgists, whose labours in this respect differ materially from others which have ministered to the welfare of First it may be urged that in no other art have the relations between theory and practice been so close and enduring. Bacon, who never undervalued research, tells us that in the division of the labour of investigation in the New Atlantis there are some "that raise the former discoveries by experiment into greater observations, axioms, and aphorisms these we call the interpreters of nature." There are also others "that bend themselves, looking into the experiments of their fellows and casting about how to draw out of them things of use and practice for man's life and knowledge . . these we call the downy m.n or ben factors" In reviewing the history of metallurgy, especially in our islands, it would seem that the two classes of workers, the in our islands, it would seem that the two classes of workers, the interpreters of nature and the practical men, have for centimes at in joint committee, and, by bringing theoretical speculatin into close connection with hard industrial facts, have "carried us nearer the essence of truth"

The main thenie of this address will therefore be the relation between theory and practice in metallurgy with special reference to the indebtedness of the practical man to the scientific investi-

We will then consider-

(1) Certain facts connected with "oxidation" and "reduc upon which depend operations of special importance to the metallurgist

(2) The influence in metallurgical practice of reactions which are either hmited or reversible.

(3) The means by which i rogress in the metallurgic art may be effected, and the special need for studying the molecular constitution of metals and alloys.

(i) The present year is a memorable one for chemisis, being the centenary of the bursh of Faraday and it he bi-centenary of the death of Robert Boyle. The work of the former has re-cently been lovingly and fittingly dealt with in the Royal Institution, where he inhoused so long. I would, in turn, briefly

400

recall the services of Boyle, not, however, on account of the comcidence of date, but because with him a new era in chemistry began He knew too much about the marvellous action of "traces" of clements on mastes of metal to feel justified in "traces" or elements on masses of metal to feel justified in pronouncing aboutiety against the possibilities of transmitation, but he did splendid service by sweeping away the firm belief that metals consist of subplus, tall, and mecury, and by giving us the definition of an element. He recognized the prepon-derating influence of metallurgy in the early history of science, and quantity tells us that "those addicted to chemistry have and quantity tells us that "those addicted to chemistry have scarce any verse but to the preparation of medicine or to the improvement of metals," a statement which was perfectly cor-rect, for chemistry was built up on a therapeutic as well as a metallurge bass. The fact is, however, this neither the prevait-ration of materials to be employed in healing, nor the study of their section, and anything the the influence on the growth of their section, and anything the section of the study of their section, and anything the section of the study of their section, and the section of the se lurgical processes. Again, strange as it may seem, theoretical chemistry was more directly advanced by observations made in connection with methods of purifying the precious metals, and by the reconstruction of the committee of the control connection with methods of purifying the precious metals, and by the recognition of the quantitative significance of the results, than by the acquisition of facts moderatally gathered in the "grew out of alchemy" nevertheless persuls, and has found expression in this Section of the British Association. As a fact, however, the great metallurgist victacid the search for a trans-position of the properties of the properties of the properties gained for its own sake. George Agricola, the most destinguished of the sixteenth entury metallurgist, in his work. "Do Orts et Causia Subterrancorum" (the v.), written about the year 1536, consist of subtype and mercury, and their precisedes ability to consist of subtype and mercury, and their precisedes ability to consist of sulphur and mercury, and their pretended ability to change silver into gold by the addition of foreign matter.

change silver into gold by the addition of foreign matter. Biringuecio (1546) says, "I am one of those who spore the ear of the additionate enterly. They mock nature when they render imperies to make the properties of the state of the tender imperies to make the properties of the network of the consideration of the wise ancients who strove to obtain possible things." In this time, rescribe the elements meant their destruction and reconstitution; in everthe-ries, his sentence. "transmittation is impossible, because in less, his sentence "transmitation is impossible, because in order to transmite a body you must begin by detroying it altogether," suggests that he realized the great principle of the statement my pitcher by the right handle, for the pseudo-chemists seek gold, but I have the true philosophy, science, which is more precious

precious."
At that cruical period what was Boyle doing when the theory of At that cruical period what was Boyle doing when the theory of At that cruical period when the period to the Balance, and came to the conclasson that the "ponderous parts of finese" could pass through glass to get at melted lead that the state of the period period that the day of the period period that he day to the period that he day to the period that he day to the period to the period that he day to the period to the period to the period that the period to the period review the present state of our knowledge in the light of the inreview the present state of our knowledge in the light of the line suggistion which have been made in the two-centrues that have passed since his own work ceased. If he turned to the end of his fine control parter his death he would see that the failure that the failure of the state of the

burnt the works of Stahl, but it was reserved for the nineteenth

bent the works of Stabl. In it was reserved for the nineteenth contury to reverently gather the abee, recognifing that when the written of the school of Becher spoke of phlogation they means that we understand by potential each effect. Pro Poyl Society had not carried out the Follows of the a "Neposition and to carried out the Follows of the a "Neposition and the College of Section that State of Mines and cause to the Royal College of Section. As well surely thank my collesque, Prof. Driver, for his vigorous defence last year, as Predicted of this Section, of the originality of the work of Prestley and Ceveralth, to which Boyle's own researches had directly left. We no our part, remembed highly the stable prof. centre point round which chemistry revolves," would hope to interest him most by selecting the experiments which arose out of the old metallurgued operation of separating the preclous metals from lead by "capellation." When, in conducting this operation, lead is heated in the presence of air, it becomes con-verted into a very find dross. Boyle had, in 161, taken this operation as the very first illustration in his "Sceptical Chemist" opention as the very fact illustration in hus "Scapical Chemist" in proof of his agginnest as to the elemental nature of metals. He would remember the quantitative work of Gober in the eighth century, who nated that the lead to heater of heater than the properties of the presence of the presence of the presence of capital control of the presence of the presence of capital centure of the presence where he doubtless continued his experiments on calcination, begun some time before, and, as if to mark his interest in the begun some time before, and, as if to mark, his interest in the operation of assyring, figures are represented on a bas-rised on his took in Westmanter Albey as conducting cupellation in a constant of the control of

fluids can freely permeate even solid metals

We may imagine with what vivid interest Boyle would

use an example with what wind interest Boyle would turn, not merely to the results of Priestley's work, but to his methods. Priestley had decomposed lithings with the electric park, and had satisfied himself in 1774, by bearing red inside the control of the satisfied himself in 1774, by bearing red inside the control of the satisfied himself in 1774, by bearing red inside the control of the satisfied himself in 1774, by bearing red inside the control of the satisfied himself in 1774, by the satisfied himself in mination of an atomic weight

mantion of an atomic weight Without of writing his attention from the phenomena of oxidation, Boyle would hid questions the interest of which is only equalled by their present obscurity, or of chemical science, described by Van 1 Hoff as that of its evolution from the descriptive to the rational period, in the early days of which the impossibility of separating physics and chemistry became evident, and so play evoid find that actenistic is now regarded from the point of the property of the control of the property of the control of the point of t

of view of the mechanics of the atom

of view of the mechanics of the atoms. Deville's experiments on dissociation have rendered it possible to extend to the groups of atoms in chemical systems the knowledge over the found seventure of the which govern the found seventure comparable in its importance to that which followed the discovery of the law of definite proportions, for dissociation has shown us that tree causes of desailed and the state of the seventure of t

at a certain critical temperature and pressure the slightest varia-tion of elther will destroy the equilibrium of the system and induce chemical change.

The aim of Boyle's chemical writings was to show that no

The aim of Boyle's chemical writings was to show that so barrier exists between physics and chemistry, and to "serve the commonwealth of learning by begetting a good understanding betwith the chemists and the mechanical philosophers," who had, as he said, "been too great strangers to each other's dis-coveries." In view of the dominant lines of research which coveries." In view of the dominant lines of research which cocupy chemists at the present time, such, for matance, as the investigations of "cosmotic pressure" and of the applications of Boyle's own law to sailt an soliton, be would seek that the book of the part in Berthollet's ducussion with Prossit, he never theless shares Berthollet's ducussion with Prossit, he never theless shares Berthollet's ducussion with Prossit, he never the part in Berthollet's ducussion with Prossit, he never the part in Berthollet's ducussion with Prossit, he never the part in Berthollet's ducussion with Prossit, he never the part in Berthollet's ducussion with Prossit, he never the part in Berthollet's ducussion with Prossit, he never the part is provided by the part of t

We need, however, no longer look at these questions from we need, nowever, no longer look at these questions should the point of view of Boyle, for our own interest in the application of chemical mechanics to metallurgy is sufficiently vivid, as instances to be given subsequently will show.

Higherto I have mainly dwell on questions relating to oxida-

Hitherto I have mainly dwell on questions relating to oxida-tion, but not less interesting is the history of the steep by which an accurate knowledge was acquired of the other great process procused by the melallargust, the one to which Paracelus was the first to apply the name of "reduction". Its explanation followed naturally from the elucation of the phenomena of combustion by Lavouster, who is continuation of Macquer's representant of 1771 proved, in conjunction with other workers, the process of the process of the process of the con-lated or oxygen. Carbon has been known for age as the most important of the reduces access that when it is "23.1 accesses." important of the reducing agents, but when, in 1772, Lavoisier heated oxide of lead and carbon together, he did not at first heated oxide of lead and carbon together, he did not at hist recognize that carbonic anhydride had been produced, simply because the volume of the gas set free was the same as if oxygen merely had been inherated. He soon, however, saw that neither the carbon slone, nor the oxide of lead alone, gave rise to the evolution of carbonic anhydride, which resulted from the the crounted of carroonic annyarine, which resulted from the material action of carroon and a constituent of the litharge. "This last observation leads us intensibly," he adds, "I overy important reflections on the use of carbon in the reduction of media." It most certainly did, and by 1815 an accurate, it meouplete, use of reduction had passed into the encyclopedias. It was seen view of reduction had passed into the encyclopedias. It was seen that the removal of oxygen from burnt metals, by parton, "gives the metals," as Tourcrys and Vasquelia put it, "i new existence" Some ten persi later Le Flay attempted to show that reduction is always effected by the intervention of carbonic mode, within cliented the classical repeated from Cary-Lasses, conde, within cliented the classical repeated from Cary-Lasses, the contract of the contract Intervention of carbonic oxide or of any other clastic fluid." I mention these facts because metallurgists are slow to recognize their indebtedness to investigators, and too often ignore the extreme pains with which an accurate knowledge has been acquired of the principles upon which their processes have been

The importance of a coherent explanation of reduction in smelting pig-iron is enormous. The largest blast-furnaces in 1815 hardly exceeded those in use in the previous century, and were at most only 40 feet high, with a capacity of 5000 cubic feet. At the present day their gigantic successors are sometimes 90 feet high, with a capacity of 25,000 cable feet. This development of the blast-furnace is due to the researches of a number of investigators, among whom you Tunner, Lowthian Bell, and Gruner deserve spacial mention. We are, however, forcibly reminded of the present incompleteness of our knowledge of the chanism of reduction, when we remember that the experiments of H. P. Baker have led us to believe that pure carbon cannot be burnt in perfectly dry and pure oxygen, and therefore that the reducing agent, carbonic oxide, cannot be produced at all

unless moisture be present.

Ludwig Mond, Langer, and Quincke, teach us not only that nickel can separate carbon from carbonic oxide, but the wholly nickel can separate earbon from carbonic oxide, but the wholly unexpected fact that dry carbonic oxide can at a temperature of 100° take up nickel, which it again deposits if heated to 150°. Mond and Quincke, and independently, Bertheidt, have since proved the exitence of the corresponding composed of from and carbonic oxide, and if may safely be concluded that in the blast-furnace smelting iron this preculiar action of carbonic basic plays an important part, and it doubtless alofs the exchination of iron by cementation. It is truly remarkable that the past year should have brought is so great an increase in our knowledge of what has place the state of anything more than "a trace" of an elastic fluid or of any third element. Cannot has further show within the last few months that the action between iron and carbon is a mutual one, for though carbon in the pure diamond form carburizes iron, the metal in its turn, at a temperature of 1050°, attacks the diamond,

invests it with a black layer, and truly unites with it.

The question of the direct carburization of iron (Darby's process) by filtering the molten metal through carbon, promises to be of much importance, for at present, as is well known, two millions of tons of steel which are made in the Bessemer converter in this country alone, are re-carbanized after "the blow"

by the addition of spiegeleisen

(2) In turning to the modern aspects of metallurgical practice. (2) In turning to the modern aspects of metallurgists' practice, we shall see that the whole range of the metallurgist's field of study is changing. It is no longer possible for him to devise a series of operations on the evidence afforded by a set of equations which indicate the completion of an operation, he has, as I which indicate the completion of an operation, he has, as I have already suggested, to consider the complicated problems which have been introduced into chemistry from the sciences of physics and mechanics. He has, in fact, no longer to deal merely with atoms and molecules, but with the influence of mass. merely with atoms and molecules, but with the influence of mass A O standid points out, we are reminded that many chemical processes are reciprocating so that the original products may be opposed processes as a state of CREMICAL EQUILIBRIUM, in which both the original and the newly-formed substances are present in definite quantities that remain the same so long as the conditions, more especially temperature and pressure, do not conditions, more especially temperature and pressure, so not undergo further change. Again, 10 very many metallurgical processes, reactions are rendered incomple e by the limitations imposed by the presence of bodies which cannot be speedily eliminated from the system, and the result may be to greatly retard the completion of an operation. The time has come when the contract of the completion of an operation. The time has come when metallungical problems if they are to be correctly understood, and """ "" "" "" province, necessary, in premither, the rare, instead by the it is, moreover, necessary to remember the part played by the surface separating the different aggregates in contact with one another. When, for instance, a reaction has to take place accomanother. When, for instance, a reaction has to take place accompanied by the evolution of gas, there must be papec into which the gas can pass. The rate, therefore, at which change takes place will obviously depend on the state of division of the must. One of the most remarkable points in the whole range of elements; pashed action engendered between two dements capable of reacting by the presence of a third body. It may be and thus at the most wonderful fact of all, that merely a trace of a third body is necessary to induce reaction, or to profoundly modify the structure of a metal H. Le Chatelier and Mouret incomy the treterite continuents in the Canada and the continuents of have pointed out that in certain cases it is inaccurate to say that

the zinc is sufficient to exert this protecting action on that metal I am satisfied that if our metallurgists are to advance their industrial practice, they must, if I may use such an expression, industrial practice, they must, it I may use such an expression, persistently think in calories, and not merely employ the ordinary atomic "tools of thought." They will then be able to state what reactions can under given conditions, take place, to indicate those which will be completed; and to avoid those that are

402

what factored was the completed; and to avoid those that are impresticable. In France, the courty of so many great metallurgust, men first Le Chatelier and Dite saw doing admirable served, by Deville within the range of practical men. And if I do not refer more specifically to their work it is for wast of space and not of appreciation, but it see winple cases of reversible actions man reducing agent, earbosic codes, is produced from the solid fuel by the rection $CO_2 + C - \pi CO_3$, a reaction which is intervente, and sate either by depolymenting the carbon into a simpler form whoch can comhon with oxygen of the CO₃ with evolution of heat, or by dissociating carbonic and with oxygen of the CO₃ with evolution of heat, or by dissociating carbonic andly of the order of the control of the control of the value of the va

Fe.O. + 3CO = 2Fe + 3CO.

Fe,O₃ + 2CO = 2Fe + 3CO,
But the gas assuing from a blast-furnace contains carbonic oxide, an important source of heat. The view that this loss of carbonic oxide was due to the fact that the consist of heave and the reducing gas was not sufficiently prolonged, led to great increase in the height has the contained of the conta attempt to smelt oxide of zinc in the blast furnace, for which operation patents have frequently been sought, in ignorance or defiance of the readiness with which the inverse action occurs, so that the reducing action of carbon on oxide of zinc may be belanced by the re-oxidation of the reduced zinc by carbonic anhydride, which is the product of the reduction A further in stance may be borrowed from an electro chemical process which has been adopted for obtaining alloys of aluminium. As as well known, all attempts to effect the direct reduction of alumina by carbon have failed, because the reaction

2(Al₂O₂) + 3C = 4Al + 3CO₄

requires 783 2 calories, while only 291 calories would result from the conversion of carbon into carbonic anhydride, therefore the reaction cannot be effected, but in Cowles's process aluminium is nevertheless liberated when slumina is mixed with charcoal and strongly heated by the passage of an electric cur-rent. This result is due, not to a simple reduction of alumina, but so its dis-ociation at the high temperature produced by the assage of a current of 1600 amperes between carbon poles, the liberated aluminium being at once removed from the system by metallic copper, which is simplicaneously present and may not be without action itself.

without action used:

An instance of the importance of these considerations is presented in the manufacture of steel by the basic process. Must care is devoted to obtaining conditions which will insure, not only the elimination, but the order of the disappearance of the only the elumination, but the order of the disappearance of the impurities from the molten poligion. In the bases process as conducted in the closed converier, the phosphorus does not disappear until the carbon has left the fluid buth, white, when the open-hearth furnace is used, the elumination of the and the same that is a same that the carbon post before the phosphorus is got ind of, a further addition of carbon is necessary. A curous and subtle case of chemical equilibrium is here presented. In the open-hearth furnace and Bessems converter respectively, the temperatures and pressures are different, and the conductions as to the presentation of oxygen classifications of the contract of the relative rates of oxidation of the phosphorus and carbon are different in the two cases, although in either case, with a given

method of solving, here must be a ratio between the phenomenon of the question is very remarkable. In the basic Beavers process the tendency of the phonophorus to longer is the bath renders an "after-blow" more supported by the phenomenon of the

of steel would be effected annually, the value of which, at the present rate of output and price of steel, is no less than a quarter of a million sterling.

The volatulization of sulphur in the converter while it is tauned by the steel in the open-hearth furnace, and the increase m the percentage of manganese which leaves the slag and "thlow," will probably be traced to the disturbance of equili-brium which attends very slight variations in the conditions, especially as regards temperature and pressure, under which the operations are conducted

In the blast-furnace the reducing action must be greatly de-pendent on the rate at which alkaline cyanides are formed, and Hempel has recently shown, by the aid of well-devised experiments, that the quantity of cyanides which may be obtained at a high temperature from carbon, nitrogen, and alkaline oxides,

a high temperature from carbon, nitrogen, and alkaline ounder, increases at the pressure become graperial branch of the must Metallingted chemistry is, in fact, as practical branch of chemical behavior of the properties of the ordinary sphere of the acadence teaching of chemistry. It is often seged that metallargical practice depends upon the application of chemical principles which are well study in every large centre of instruction in this country, but a long series of chemical reactions exist which are of visit importance to the metallargiar, though they which are or vital importance to the metallargial, though they are not set forth in any British minual of chemistry, nor are dealt with in courses of purely chemical lectures. If feel bound to must upon this point, because, as Examiner Metallargy for the Science and Art Deportment, I find that purely analytical and laboratory methods are so often given in the belief that they are applicable to processes conducted on a large seale, and at

high temperatures.
We are told that technical instruction should be kept apart from scientific education, which consists in preparing the student rrom scientific cuscation, which consists in preparing the student to apply the results of past experience in dealing with entirely new sets of conditions, but it can be shown that there is a whole side of metallurgical teaching which is truly educational, and leads students to acquire the habit of scientific thought as surely

reads students to fought re the name of scientine thought as surely as the investigation of any other hranch of knowledge. It is, in fast, haddly possible in a course of theoretical chemistry to devote much attention to specific cases of industrial practice in which reactions are incomplete, because they are limited by the presence of bodies that cannot be directly eliminated from the chemical system Take, for instance, the long series of reactions studied by Platitier, who published the results of his investigations in his celebrated treatise, "Die Metallurgische Rostprozesse," Freiberg, 1856, whose work I have chosen as a starting-point on account of our presence in South Wales near the great copper-suching district of Swanses. A complex sulphide, of which copper is the main metallic constituent, contains some fifty ounces of allver to the ton. The problem may be supposed for the present to be limited to the hidden, and the student deriving his knowledge from an ex-cellent modern chemical treatise would find the case thus

"Ziervogel's process depends upon the fact that when argentiferous copper pyrites is roasted, the copper and iron sulphides are converted into insoluble oxides, whilst the silver is converted into insoluble oxides, whilst the silver is converted into a soluble sulphate, which is dissolved out by lixivating the roasted ore with hot water, the silver being readily precipitated from this solution in the metallic siler. from this solution in the metallic state.

from this solution in the metallic state."
It is errain that if an observing exposured in model in the little of t

the bed of a rewrberstory furnace. Suppose the material la what is known as a complex regulan, as imported into Swanser or produced at Freeberg, to which are added rich nature sulphides. The mitures then consists of subplides manify of iron and copper, with some sulphide of lead, and contains fifty or astroyonces of allere to the ton, and see grams of gold. It may also contain small quantities of arsenic and antimorneys a method, and mittonoides, and sulpho salts, usually with copper as a base

also contain small quantities of arsenic and antimony as arsenides, antimonodes, and sulpho salts, usually with copper as a base. The temperature of the furnace in which the operation is to be performed is gradually raised, the atmosphere being an oxidizing one. The first effect of the elevation of the temperadising one. The first enect of the cleration of the composi-ture is to distil off sulphur, reducing the sulphides to a lower stage of sulphurization. This sulphur burns in the furnace atmosphere to sulphurous anhydride (SO₂), and, coming in consatisfact with the material undergoing oxidation, is converted into sulphurie anhydride (SO₂). It should be noted that the material of the brickwork does not intervene in the resations, except by its presence as a hot porous mass, but its influence is, nevertheless, considerable. The roasting of the sulphides presents a good case for the study of chemical equilibrium. As soon as the sulphiurous anhydride reaches a certain tension, the oxidation of the sulphide is a rested, even though an excess of oxygen he present, and the oxidation is not resumed until the action of the draught changes the conditions of the atmosphere of the furnace, when the lower sulphides remaining atmosphere of the furnace, when the lower sulphides remnaining are slowly oxidized, the copper sulphide being converted into copper sulphase being converted into copper sulphase mainly by the intervention of the sulphine analydride formed as indicated. Probably by far the greater part of the floor aulphide only becomes sulphase for a very brief period, heing decomposed into the oxides of iron, mainly ferric period, heing decomposed into the oxides of iron, mainly ferric oxide, the sulphur passing off. Any silver sulphide that is present would have been converted into metallic silver at the outset were it not for the simultaneous presence of other sulphides, notably those of copper and of iron, which enables the silver sulphide to become converted into sulphate. The lead sulphide is also converted into sulphate at this low temperature The heat is now raised still further with a view to split up the salphate of copper, the decomposition of which leaves oxide of er If, as in this case, the bases are weak, the sulphuric copper If, as in this case, the bases are weak, the sulphates of anhydrice escapes mainly as such; but when the sulphates of stronger bases are decomposed, the sulphuric anhydride is to a great extent decomposed into a mixture of sulphurous anhydride and oxigen The sulphuric anhydride, resulting from the de-composition of this copper sulphate, converts the silver into composition of this copper suppante, converts the silver mu-sulphate, and maintains it as such, just as, in turn, at a lower temperature, the copper itself had been maintained in the form of sulphate by the sulphure analydride eliminated from the ron sulphide. When only a little of the copper sulphate remain undecomposed, the silver sulphate begins to split up, and the furnace charge must therefore be immediately withdrawn, or the whole of the silver sulphate would be converted into metallic silver, partly by the direct action of heat alone and partly by reactions such as those shown in the following equations --

$$Ag_{8}SO_{4} + 4Fe_{8}O_{4} = 2Ag + 6Fe_{8}O_{8} + SO_{2},$$
 $Ag_{8}SO_{4} + Cu_{8}O = 2Ag + CuSO_{4} + CuO.$

If the charge were not withdrawn, the silver would thus be effectually removed from the solvent action of water, and the smelter's efforts would have failed entirely. The charge still contains lead subjuste, which cannot be completely decomposed at any temperature attinuable in the rosting furnace, except in evidence to the control of the series of the control of

Sh₂S₂ + 3H₄ = 3H₄S + 2Sb between hydrogen and sulphide of antimony is, however, endothermic, and could not, therefore, take place without the aid

which is afforded by external heat. The facts appear to be as follows: subjide of antimony, when beated, discourtes, and the tension of the sulphus vapour would produce a state of equilibrium if the sulphus thus biderated were not seited by the hydrogen and removed from the system. The equilibrium is thus destroyed, and fresh sulphus is discounted; the general result being that the equilibrium of the system is continually restored and destroyed until the sulphus is decomposed. The restored and extremy during the sulphus is recognized, as do as does also the ancein; a portion of which is volatilized as sulphuse.

The man object of the process which has been convidered in the formation of soluble sulphate of uters. If a renel is and animony have not been eliminated, their presence at the end of the operation would be specially motionevenent, as they gave rue to the formation of arkinate and antimomate of silver, insoluble in water, which may necessitate the treatment of the residues by an entirely different process from that which has hitherto been considered.

It will have been ewdent that effecting this sense of changed demands the exercise of the utnot skill, care, and patence. The operations beginning at a dull red heat, or a temperature of men god, are completed at you, which a range, that is, of 200 of emats of subplicates, which would impose the reactions, and as has been shown, an undue elevation of temperature of emitted range would, at any singe, have been fault to the telescape of sight and touch which enables an operator to judge by the end of rough tests, but mainly from the tint of the telescape of sight and touch which enables an operator to judge by the end of rough tests, but mainly from the tint of the telescape of sight and touch which enables an operator to judge by the end of rough tests, but mainly from the tint of the return of the sight of the si

Proceeding yet one use further, suppose that the cooperineller takes possession of the rendail mass, consuiting manily of outset of copper, he would smelt it with fresh adjubide ore, reconstitutes containing some mall proportion of copper. The duplacement of the copper from this allecte may be effected by fissing in with subjuble of iron, a fasible subjuble of rone and copper being formed, which restally separates from the size, anded to the world's annual production. Proceeding yet a step further, suppose the amelier to have redused his copper to the metaller state. If arments had been originally present in the metaller state. If arments had been originally present in the process, in extracting small quantities of arments which result he smeller! efforts. Copper, noteoner, containing arrenic chinatics of gases on the presence of settings of the test of the second presence of the copper, and would be fast to its use in submarine telegraphy. If you the other hand, the copper-smeller has to remove may very from mere traces up to a presence of the copper, and would be fast to its use in submarine telegraphy. If you the other hand, the copper lamended for the maker of locomother dise-boses, increase the jetterical treatance of the copper, and would be fast to its use in submarine telegraphy. If you the other hand, the meller will list need a case have no indecement to employ the basic featured lining which Mr Gilbritist has offered bim, nor will be case but the precial methods for the removed of amenic with which he is familiar. It may all seem simple enough, but the modern process of copper-smelling has been laborically built up, and has a long and increasing pedigree which may be traced to at least the eighth century, when Gaber described the regulu, "coare metal," as being "of a most clean and plea-sure to the companies of the metal and the companies of the com-summent of the companies of the companies of the companies of the sant violet colour," and indicated the reason for the difference.

404

(3) The foregoing Instances have been given to indicate the general nature of metallurgical chemistry. It will be well now to show how the great advances in metallurgical practice have been made in the past, with a view to accertain what principles should guide us in the future.

been made in the past, with a view to ascertain what principles should guide us in the fature.

It is a grave mistake to suppose that is industry, way some should guide us in the fature.

It is a grave mistake to suppose that in judicity, way some produced of a master possessed of some new girl of invention; yet we have been reminded that we are apt to be rewrected to these alone, as it the nation had been unprogressive and suddent whether the suppose of the production of the suppose of the production of the suppose of the production of the production. Whether the investigators are few or many, and consequently whether progress is suffered to the production of parts such case. Whether the investigators are few or many, and consequently whether progress is suffered to the production of the production. Whether the investigators are few or many, and consequently whether progress is allow or rapid, will depend no nonline sustained to whether the production of the production

precedent, but it should be remembered that though the few successes, which have been attained in the course of ignorant practice, may come into prominence, none of the countless failures are seen. I would briefly direct attention to certain processes which have

failures are seen.

I would briefly direct attention to certain processes which have been adopted since the year 1849, when Dr. Percy preseded over the processes of the process

It must not be supposed that when commercially part capter has on the transce but may be be structured to could, that his principles covery of restrictions overy. It might be thought that the few turnle per count, of instances the contractions covery in the contraction of the country of the

process had been prepared by the theoretical work of Andrews, 1245, and of Favre and Silbermann, 1852, whose work on the calonific power of various elements showed that silicon and phosphorus might be utilized as fuel, because great heat is engendered by their combestion.

by their combustion.

The basic process for removing phosphorus, a process of great national importance, the development of which we owe to Thomas and Guichrist, a neutrey the outcome of purely theoretical teaching, in connection with which the names of Griner and Percy deserve special mention. In the other great group of processes for the production of steet, those in which Stremnis's of processes for the production of steet, those in which Summers a regenerative furnace is employed, we have the direct influence of a highly trained theorist, who concluded his address as Pre-sident of this Association in 1882 by reminding us that "in the great workshop of Nature there is no line of demarcation to be drawn between the most exaited speculation and commonplace practice." The recent introduction of the method of heating by radiation u, of course, the result of purely theoretical con-

The progress in the methods of extracting the precious metals The progress in the methods of extracting the precious metals bacter very great, both on the chemical and engineering sides, but it is cursous that in the metallargy of gold and silver, many ancent processes survived which were surveed as emplrically—for the contract of the contract of

while chievide of silver is being formed.

The influence of scientific investigation is, however, more evident in that portion of the metallurgic art which deals with the adaptation of metals for use, rather than with their actual extraction from the ores.

Only sixteen years ago Sir Nathaniel Barnaby, then Director Only sixtem years ago Sir Nathanuel Barnaby, then Director of Naval Construction, wrote, "Or distrust of seal to se great that the material may be said to be aitogether tunned by private that the material may be said to be aitogether tunned by private that the material may be said to be aitogether tunned by private the said of t

were being built of steel in the United Kingdom. Why is it, then, that steel has become the material on which we rely for our ships and for our national defence, and of which we have a spindial structure as the forth Bridge is contracted? It is because, slide by side with great improvement in the quality it is because, slide by side with great improvement in the quality heart process, elaborate researches have shown that is the most suitable mechanical and thermal treatment for the meeting but the adaptation of seel for industrial use is only typical, as the innerest in this branch of metallurgy generally appears for the motions to be centred in the question whether meetia can, mechanical stress from a normal state to an allotropic one, or whether meetia metange even the motion to be desired. whether metals may even exist in numerous isomeric states.

whether metais may even exist in numerous isomeric states. It is impossible to deal historically with the subject now, further than by stating that the belief of more than one "modification" is old and widespread, and was expressed by Paracelism, who thought that copper "contains in itself its female," which could is old and widespread, and was expressed by Farsecisia, who thought hat copper "contains in litell its female, "which could fusion and malleability" as steel and iron differ. Within the last few years Soltiumsberger has shown that two modifications of copper can exast, the normal one having a density of 8 of, while that of the alteropic medification is only 80, and is sellowed the solitonian contribution in one of the solitonian contribution on ordinary copper. It may be added that Lard Rayleth's pick not the investigation of the sumpler chemical reactions has been partly me, in the case of coppor, by the experiments conducted by 1½. Velyo on the conditions of chemical change conducted the sellowing the conditions of the conditions of the sellowing the conditions of the sellowing the sellowing the conditions of the sellowing the s

fead-tin alloys polymerization may take piace after the alloys have become solid, and it seems to be admitted that the same save the course fold, and it seems to be desirted that the sare cases underlied both polymerisation and allorropy. The pheno-menon of allorropy is dependent upon the number of the atoms neach molecule, but we are at present far from being able to any what degree of importance is to be attached to the relative distance between the stoms of a meal of to the "politic of one alloyed or free, and it must be admitted that in this respect organic chemistry as far in dwance of metallurgic chemistry. I cannot, as yet, state what is the atomic grouping in the brilliantly-coloured gold-alminium alloy. And, which I have had the good fortune to discover, but, in it, the gold is probably present maintains.

Much valuable information on the important question of allotropy in metals has already been gathered by Pionchon, Ditte, Moissan, Le Chateller, and Osmond, but reference can only be made to the work of the two latter. Le Chateller concludes that in metals which do not undergo molecular transformation the dectars which to the most endergo molecular transformation the clectrical resistance increases proportionally to the temperature. The same law holds good for other metals at temperatures above that at which their last change takes place. For example, in the case of nuclei above 340°, and in that of iron above 850°. It is probable that minute quantities of foreign matter, which

profoundly modify the structure of masses of metal, also induce altoropic changes. In the case of the remarkable action of importate upon pure gold I have auggested that the modifications which are gold and the sease of the specific variations which are produced may have direct connection with the periodic law of Meeticlesff, and that the causes of the specific variations of the second of the sease of the specific variations of the sease of the specific variations of the sease of the specific variation is of great industrial importance, aspecially in the case of iron is and Comond, whose secletient work I have already brought before the members of this Association is a fecture of the sease as the sease of the allotropic changes. In the case of the remarkable action of imthan that of iron tend to hasten the change of β to α iron. It is, however, unnecessary to dwell upon this subject, as it was dealt with last year in the address of the President of the

Association.
It may be added that the recent use of nickel-steel for armouphate, and the advocacy of the use of copper-ateel for certain purposes, it the industrial justification of my own views as to the influence of the atomic volume of an added element on the mechanical properties of rose, and it is remarkable that the two bodies, silicon and aluminame, the properties of which when in a five state are so totally different, should, nevertheless, when a five state are so totally different, about, not a same way. Silicon and aluminame have allowed the state of the state

and aliminium next amost the rame atomit volumes. The consequences of allotropic changes which result in alteration of structure are very great. The case of the tin regimental buttons which fell into a shapeless heap when exposed to the rigorous winter at St. Petersburg, is well known. The recent remarkable discovery by Hopkinson of the changes poses to the regroup winder at St. Peterbourg, a well known in the density of includence and the state of the

The molecular behaviour of alloys is indeed most interesting. W. Spring has shown, in a long series of investigations, that

alloys may be foresed at the ordinary temperature, provided that manute particles of the constituent metals are submitted to great the constituent metals are submitted to great favour of the two that an alloy can be produced from its constituent metals with but slight pressure if the temperature to which the mass is submitted be above the mening-point of the easily faults constituent. A further nature at thus afforded of the fact that a variation of either temperature or pressure will effect the unson of solids. It may be added that B. C. Damies of the conference of an interesting relation between the conference of an interesting relation between the conference of an interesting relation between the conference of the conference of an interesting relation between the conference of the conference of an interesting relation between the conference of the conference of an interesting relation between the conference of the conference of an interesting relation between the conference of the conference of an interesting relation between the conference of the conference of an interesting relation between the conference of the conference atomic weight of metals.

Few questions are more important than the measurement of very high temperatures Within the last few years H Le Chateller has given us a thermo-counte of platinum with platinum containing to per cent. of rhodium, by the aid of which the problem of the measurement of high temperatures has been problem of the measurement of bign temperatures has been greatly simplified. A trustworthy pyrometer is now at band for daily use in works, and the liberality of the Institution of Mechanical Engineers has enabled me to conduct an investigation which has resulted in the adoption of a simple appliance tion which has resulted in the adoption of a supple appliance for obtaining, in the form of curves, photographic records of the cooling of masses of metal A report on the subject has already been submitted to a Committee, of which the Director-General of Ordinance Factories is the Chairman; and Dr. Anderson, to whom I aim indebted for valuable assistance and derice, intends to add this new method for obtaining sattographe curves of pyrometroe measurements to the numerous self-recording appliances used in the Government factories which he controls. It has proved to be easy to ascertain, by the add of this pyroutlets makes the control of the properties of the p whom I am indebted for valuable assistance and advice, intends

Prof. H. E. Armstrong holds that the molecules of a metal can mate to form complexes with powers of coherence which vary with the presence of impurity. Crookes, by a recent beautiful investigation, has taught as now electrical evaporation as alloy mass, by form the property of the prop

the molecular contribution of metals, I would specially refer to the excellent work of Heyocck and Nevella, who have excessed on the effect of Impority on the Investment of the State of State

investigations conducted at the Watertown-Aremal, Maschuetta, not to mention the numerous Conlineatal testing laboratories directed by such men as Bauschinger, Jenny, and Tetmajer. Perhaps the most important recent work is that described by Prof. Martens, of Berlin, on the influence of heat on the strength of tron

I must have duel at length on all these mattern without often Ball his service to mediturely that I loop to reader by earnerly pleading for the more extended teaching of the subject throughout the country, and for better laboratories, arranged on the model of engineering laboratories, in which the teaching is the model of engineering laboratories, in which the teaching is reconcluded with the aid of complete, though sealily "plant." The Sceneos and Art Department has done great and lasting secret by directing that made with regard to laboratories in works, which are too often mere theids placed, say, behind the boller-house, when may we hope to rival the German chemical firm which has recently spent £19,000 upon its laboratories in which research will be vigorously goodwated? There is hardly any breach of morphic chemistry back of the place of the sum of the properties of the sum of the properties of the union timportance to him.

mechanics are of the utmost importance to him. The wide range of study upon which a metallurgical student is rightly expected to enter is leading, it is to be feared, to the control of the student of t

prefereice for chemists who have been trained in works, to those who have been quicated in a college inboratory.

In making and metallurgy, with a view to the full development of the mineral wealth of a stollar, in well known. The issues at stake are as vast, that in this country it was considered destrable to provide a centre of instanction in which the reaching of mining said are into the contraction of the contraction of the contraction of the Covernment. With this end in view, the Royal School of Mines was founded in 1854, and has supplied a body of well-stake of the Covernment. With this end in view, the Royal School of Mines was founded in 1854, and has supplied a body of well-stake of the Covernment. With this entire the view of the Covernment of the Covernment has recently takens a step in a vivance, and has further recognized the national importance of the teaching of mining and metallargy by directing that the School of Mines shall be incorporated with the Royal College of the teaching of mining and metallargy by directing that the School of Mines shall be incorporated with the Royal College of the teaching of the believe, discusted to lead the securities cutter.

It is to be feared that as regards metalliferous mining our country has veen it best days, but the extraordinary mineral wealth of our colonies has recently been admirably described by end of the extraordinary metal delivered early in the present year on his appointment to the chair so long held by Sir Warington Swith (Lenguezering, oil. i, p. 20 of test). We shall, however, be able to rightly is opened next year, and the nation will have reason to be grateful to Sir Frederick Abel for hear he is development of this great minimum, which will become the development of this great minimum, which will become the resources, as well as a centre of information.

The rayed growth of technical literature renders it unnecessary for a President of a Section to devote his address to recording the progress of the subject he represents. As regards the most important part of our national installary, this has, moreover, been admirably done by successive Primarents of the references would have been made to the unit processes which have been adopted since Percy occupied this chair in 1859. I have not done to, because an assumention of the processes would have been wholly inadequate, and a description of them when the processes would have been wholly inadequate, and a description of them may be well to remusafful Section of sive of the more promisent additions the art has releved in the last half century, and to offer a few statements to daw the magnitude on which operations are

conducted. As regards uno, in the last twenty-five years the price of sized his been reduced from £5 per ton 0.6 per ton, but, after giving the world the inestimable boson of cheeps steel by the known of Essemer and of Senemes, we were somewhat slow to accept the teaching of experiment as to the best method of treating the error material, on the other hand, Haffield has of the mannfacturer, and J. Kiley has done much to develop the use of nuclei-testing the error.

In the case of copper, we have mainly contributed to the extraordinary development of wet processes for its extraction from poor sulphides, and have met the great demands for pure metal by the wide adoption of electrolytic processes.

"An event and processor metals, in contary a well to the front, or force Britain and her colones produce about 3g per cent. of the gold supply of the world, and it may be well toadd, as an andsaxton of the seale on which operations are conducted, that in London alone one to gold and five tons of silver builloon per perfecting the method of sasay by which the value of gold and silver as atcertained, and during my twenty years' connection with the Kopyl Mint I have been responsible for the accuracy of the standard insenses of no less than twe handred and fifty-few handred thousand pounds stering. In the case of the plantom industry we owe its extraordinary development to the skill and maderal thousand pounds stering. In the case of the plantom industry we owe its extraordinary development to the skill and energyine of successive members of the firm of Johnson, Matthey, the contemps of successive members of the firm of Johnson, Matthey, the contemps of the state of the material dealt with may be galacted from the statement that two and a half handred the state of the state of the material dealt with may be galacted from the statement that two and a half handred the state of the state of the material dealt with may be galacted from the statement that two and a half handred the state of the material dealt with may be galacted from the statement that two and a half handred the state of the state of the material dealt with may be galacted from the statement that two and a half handred the statement that we would be statement that we contain the statement when the contains the statement of the contains the statement of the statement of

I with a were possible to record the services of those who have advanced mentalizary in connection with that Association, but the hunsations of twice render it difficult to do more than to have advanced mentalizary in connection with that Association, but the hunsations of twice render it difficult to do more than to which the property of the prope

In drawing this address to a close. I would point to the great In drawing this address to a close, I would point to the great importance of extending the use of the less known meats, importance of extending the control of the control be a rapid increase in the number of metalingical processes that depend on reactions which are set up by submitting chemical systems to electric stress. Incidental reference should be made to the growing importance of sodium, not only in cheapening the production of sluminium, but as a powerful weapon of research. In 1849, when Percy was President of this Section, magnesium was a curiosity; now its production constitutes a considerable industry. We may confidently expect to see barium and calcium produced on a large scale as soon as their utility has and calcium produced on a sarge scale as soon as men unity may beendemonstrated hyresearch Minerals containing molybdenum are not rare; and the metal could probably be produced as cheaply as tin if a use were to be found for it. The quantities of vanadium and thallium which are available are also far from inconsiderable; but we as yet know little of the action of any of these metals when alloyed with others which are in daily use.

The field for investigation is vast indeed, for it must be remem-In eneigh for investigation is vast indeed, for it must be remembered that valuable qualities may be conferred on a mass of metal by a very small quantity of another element. The useful qualities imparted to platinum by iridium are well known. A small quantity of tellurium obliterates the crystalline structure of bis quantity of tellurum obliterates the crystaline structure of but must; but we have lost an ancient art, which enabled brittle must; but we have lost an scient art, which enable brittle statement of the statemen organic compounds, in order to rate alloys from the obscurity in which they are at present left.

It must not be forgotten that metallurgical enterprise rests on a scientific knowledge, (2) capital, and (3) labour, and that, if the results of industrial operations are to prove renumerative, much must depend on the relation of these three elements, though it is difficult to determine accurately their relative importance. A modern ironoworks may have an army of thousand workmen, and commercial success of failure will de tnousance workment, and commercial success or fainte will de pend in so small measure on the method adopted in organizing much interest at the present time that I do not heatate to offer a few words on the subject.

Many examples might be borrowed from metallurgical enter-prises in this and other countries to show, that their nature is

prises in this and other consistent to show that their nature is often presented by what appear to be comparatively slight causes. Capitalists amply appear to be comparatively slight causes. Capitalists amply the consistency of the comparative slight causes. It is not the consistency capitalists are capitalists and the tabloring causes the notation would then severely suffer. It is only reasonable, therefore, that if capitalists are exposed to great risks, they should, on the event of ancoess, receive the greater part of the profix-free is a welepsed feeling that the interests of capital said There is a wedespread feeling that the interests of capital and abour must be susquanticle, and as it is impossible to ignore abour must be susquanticle, and as it is impossible to ignore apprehension, it becomes the duty of all who possess influence to strive not merryl for peace, but to range themselves on the side of justice and humanity. The great labour question can-vered the susquantial properties of the susquantial pro-served to the susquantial properties of the susquantial conversible must be held invisiblely but it must be admitted that there was a time when capital had become arbitrary, and some still of unrel as a susquantial problems of the susquantial pro-tained that the susquantial problems of the susquantial pro-tained in the susquantial problems. self-defence. If, however, we turn to the action of the leaders of trades unions in the recent lamentable strikes, we are pre-sented with a picture which many of us can only view as that of

tyranny of the most close and oppressive kind, in which indi-vidual freedom cannot even be recognized. There are hundrels of owners of works who long to devote themselves to the true welfare of those they employ, but who can do little against the inflaence of the professional against, and are merely saddened by contact with prejudice and ignorance. by correct that some system by which the workman participates in the profits of enterprise will afford the most hope of putting an end to labour disputes, and we are told that profit-sharing tends to destroy the workmen's sense of social exclusion from the capitalistic board, and contents him by elevating him from the capitalistic noard, and contents him by elevating him from the preacrious position of a hired labourier. No pains should, therefore, be spared in perfecting a system of profit-sharing. Pensions for long service are great aids to patience and fidelity, and very much may be hoped from the fact that strengous efforts

are being made by men really competent to lead. The Report of the Labour Commission which is now sitting will be looked for with keen interest Watchful care over the health, interests, and instruction of the employed is exercised by many owners of works; and in this respect the Dowlals Works, which are being transplanted into your midst at Cardiff, have long presented a transplanted into your min's at Caraiti, nave long presented a noteworthy example. Workmen must not forget that the choice of their own leaders is in their own hands, and on this the future mainly depends. "We may lay it down as a perpetual law that workmen's associations should be so organized and governed as to furnish the best and most suitable means for attaining what is aimed at-that is to say, for helping each indiattaining what is aimed at—that is to say, for helping each individual member to better his condition to the utmost in body, mind, and property. These words will be found in the Engy-clical Letter which Pope Leo XIII, has recently issued on the "Condition of Labour." To me it is specially interesting that the Bishop of Rome in his foruble appeal again and again cites the opinion of St. Thomas Aquinas, who was a learned chemist as well as a theologian

Those of us who realize that "the higher mysteries of being, Those of us who realize that "the higher mysteries of being, if penetrable at all by human intellect, require other weapons than those of calculation and experiment," should be fully sensible of our individual responsibility. Seeing that the study of the relations between capital and labour involves the consideration of the complex problems of customes, the solution of which is at present hidden from us, we shall feel with Andrew Lamp that "where, as matter of sciences, we know mobiling, we can only write the message of our temperature?" Say one of the consideration of vent them from driving our national industries from these shores and I would ask those to whom the direction of the metallurrical and I would ask those to whom the direction of the metalitrigical works of this country is confided to remember that we have to deal both with metals and with men, and have reason to be grateful to all who extend the boundaries, not only of our knowledge, but also of our sympathy

SECTION D

Blut ogy.

OPENING ADDRESS BY FRANCIS DARWIN, M.A., M B., FRS., FELLOW OF CHRIST'S COLLEGE, CAMBRIDGE, PRESIDENT OF THE SECTION.

On Growth-curvatures in Plants.

A SERDINO plant, such as a rough sunflower, when growing in a wate of nature, grows straight up towards the open sky, while its main root grows straight up towards the open sky, while its main root grows straight down towards the center of the earth. When it is artificially displaced, for instance by jump the however poor into such soon troot and when execute certain curvatures by the straight of the property of the straight of the property of the straight o Curvatures such as these, whether executed in relation to light, agrivation, or other inflaences, may be grouped together as growth-curvatures, and at is with the history of our knowledge on this subject that I shall be occupied to-day, or the subject of the subject to the subject to the subject to gravitation, but the phenomens in question form a natural growp, and at will be necessary to refer to helitoripian, and, nideed, to other growth-curvatures. The listory of the misject till relation two branches, which it will be consentent to

subject tritices must be obtained; study separately When a displaced apogeotropic organ curves so as to become once more vertical, two distinct questions arise, which may be briefly expressed thus:—

(1) How does the plant recognize the vertical line; how does it know where the centre of the earth is? (2) In what way are the curvatures which bring it into the vertical ine executed?

408

The first is a question of irritability, the second of the mechan-The first is a question of irritability, the second of the mechanism of movement. Sachs has well politiced out that these two more properties of the propert

The history of our modern knowledge of geotropism may conveniently begin with Hofmeister's researches, because in an veniently begin with itomesser's researches, because in an account of his work some of the points which re-occur in recent controversy are touched, and also because in studying his work the necessity of dividing the subject into the two abovenamed headings, Irritability and Mechanism, will be more

named headings, Irritability and Mechanism, will be more clearly perceived.

In 180 (Merchiel, b. Eiche, Ger. d. Witz.), Mefendere In 180 (Merchiel, b. Eiche, Ger. d. Witz.), Mefendere State of the Merchiel of State of Merchiel of State When the shoot comes to restrict to be no longer straight, but to have soquired a permanent beed towards the sade on which it was struck. In explaining this phenomenon Hofmeit-eric described these conditions of growth which give rise to what is known as the tension of issues, these facts are still an important part of botanical study, though they hold quite a different position from that assigned to them by Hofmeister. The classification into active or erecule time and passively extended tissue was then first made. The pith, which passively extended tissue was used use made. In epits, which is compressed, and strives to become longer, is the active or erectile part, the cortical and vascular constituents being passively extended by the active tissue. Hosmeister showed that when the shoot is volently bent the elasticity of the pa-site tons were the shoot is violently own; the elasticity of the pa-silve tissue on the course and is I injured by overstretching. The system must assume a new position of equilibrium, the passive tissues are now no longer equally resisting on the two sides, and the shoot must necessarily assume a curvature towards that aide on which passive tissues are most reassing.

In a second paper, in 1860, Hofme aler (Beruhted k. Sachs. Get d. Wiss.) applied these principles to the explanation of geotropism. It is true that in his second paper he does not refer to the former one, but I think that it can hardly be doubted that the knowledge which supplied the material for his paper of 1859 suggested the theory set forth in 1860. He had shown that in the system of tensions existing in a turgescent shown that in the system of tensions existing in a turgescent shoot lay the power of producing artificial curvatures, and he applied the same principle to the natural curvatures. When an apposperitype copies in placed in a houtonial position, if foresister resisting, so that they yielded more resisting to the proper side to the longitudinal pressure of the turgescent pith. The ystem in such a case comes to rest in a new position, the boot curving upwards, the passive tissues on the upper and lower sides once more resus the expansion of the pith in equal to the property of the property as far as mechanism is concerned, is in rough outline practically the same as certain modern theories, which will be discussed in

the sequel. His views resembled more modern theories in this, too: I clearly recognized that they were, metatis metandis, applicable to acellular organs. The manner in which Hofmeister compared the mechanics of multicallular and acellular parts was pared the mechanics of multicaturs and accituar parts was currous; nowakays we compare the integescent pith of a growing shoot with the hydrostatic pressure inside the sociliate organ. Just as the pressure inside a single cell stretches the cell-walla, so in a growing shoot the turgescent pith stretches the cortex.

⁴ Kn ght had previously suggested an explanation (Philosophical renections, 1805), which is so far smiller, that the susking downwards by ravitation of the judges of the plant is supposed to be the prenary cause of pogeoti-pusm Knight's explanation of positive geotropism is practically he same as Hofenester's pogeotropum Knight's explanation of positive geotropum is practically to same as Hofmenster's "Sache's term acellular is, in the present connection, equivalent to succliniar.

NO. 1139, VOL. 44]

As path is to cortex, so as cell-pressure to cell-membrane. But Hofmeister would not have accepted any such comparison. In the case of accliular organs he localized both the erectile and passively extended by the active growth of the inner layers of the cell-wall.

It is remarkable that the obvious source of power which th pressure of the cell-sap against the cell-walls supplies should have been so much neglected This may perhaps be accounted for as a revulsion against the excessive prominence given to

osis in the works of Dutrocher

omnous in the works of Districtlet. The great fail of Hofmeister's views was the purely mechanical minner in which he believed changes in extensibility in the passers immess to be brought about. When an apages—on the property of the prope obvious cases of response to stimulation as the movements of Mimona. In this respect it was a retrogression from the varw of some earlier writers, Distrocher's clear statement (1824) as well be quoted lower down. Territorian, as his "Flynologies" (1838), speaks of gestropism as a Triet, or impalies, and adds that though there is no question of desire or resension, as in the impulses of animals, yet geotropism must be thought of as some large higher than a merely mechanical or chemical action.

thing higher than a merely mechanical or chemical action. In taking used a view Holmester naturally neglected the basis and the state of the state o what are now universally considered parts of a single pheno-menon—vis negative and positive geotropium. He gave the pending up a riem. It is well known that he supposed a root to be plastic, and to bend over by its own weight, like a tallow condide on a hot day or a piece of heated scaling wax. The development of a unified view of feliotropium, geotropium,

and other similar curvatures is a part of my subject, and for that reason the curions want of unity in Holmeister's views is in-

teresting.
In 1865, Sachs published his "Experimental-Physiologie"
He here accepts Hofmeister's views with certain modifications.

Irritability,

When by a touch on a tugger the explosion of a putol is caused, we do not say that the putol is irriable, but when in an ongassan a tunilar release of source) persenge occur, we apple the term irriability to the phenomenon, and we call the influency which produced the change a stimulus. At the time (1865) there was as far as I can discover, no literal that growth—time (1865) there was a far as I can discover, no literal that growth—time (1865) there was a far as I can discover, no literal that growth—time (1865) there was a far as I can discover, no literal that growth—time (1865) there was a far as I can discover, no literal that growth—time (1865) there was a far as I can discover, no literal that the control that the growth of the control that the growth of the control that the growth of the control that the

1 "Recherches anat. sur la Structure Intima, &c." (1844), p 107. Dutro-chet, however, was not consistent in this matter, and later on gave explana-tions as mechanical as Hofmeister."

botanical mind should have taken more than fifty years to assimilate Dutrochet's new.

In 1868 Albert Bernhard Frank published his valuable in 1869 Albert Bernhard Frank published his valuable for the published has been supported by the published has been supported in more than one went published his published has been supported in more than one went published his published his office and the man fart suggested in initiation of the existing expression "heliotrophim." This uniformity of nomenclature had an advantage beyond mere convenience, for it served to emphasize the were that the curvatures were allied in character. His crit-tion of 1 160 neutre and Sacha were directed against the follow-

clams for requirements and other positively georopie organs (i) That roots and other positively georopie organs band owing to plasticity. By repeating and varying certain older experiments, Frank helped materially to establish the now older experiments. Frank helped materially to establish the now universally accepted wew that pouting egotropless as an extre-not a passive, curvature, and that it depends, like apogeotropism, on on unequal distribution of longitudinal growth Here, again, he introduced unity, bringing what had been considered different phenomens under a common heading. By studying the distribution of growth and of tension in a variety of curvatures he

helped still more to unite them under a common point of view.

(ii) He showed that Hofmeister's classification of organs into those (1) which have and (2) which have not tension, was valueless in connection with growth-curvatures; that is to say, that apogeoropsium is not necessarily connected with the form of longitudinal tension found in growing shoots, and that the distinct kind of tension existing in roots has no connection with their positive geotropism. His work thus served to hring the their positive geotropism. His work thus served to bring the subject into a more purely physiological condition, not only by subject mot a more purely pnysiological condution, not only or his downight opposition to a mechanical theory backed by the great name of Hofmeister, but also by giving importance to physiological individuality In 1879, Frank published a more important work, "Die natur-tiele wagerechte Richtung der Pfianzenthellen." This paper

In 1870. Frank published a more important work, "Due naturaliche wagerechte Richtung der Pfinanzentellen." This paper not only tended to muit geotroplim and heliotropasm by proving the phenomena described to be common to both acagories, but der help the properties of the phenomena described to be common to both acagories, but horizontal growth must be the field of with by showing that horizontal growth must be the field of with by showing that horizontal growth must be used to be a secondary of the resetton of plants to light and gravatation which has been most fruitful Famils showed that certain parts of plants, for entance the horizontal growth and the state of the control of plants to light and gravatation which has been most fruitful Famils showed that certain parts of plants for entance the horizontal parts of the pattern on negative, but transcere. Ten years later transcered to it. Here, and Frank is a new uppe of geotropain, number positive and negative, but transcere. Ten years later than the pattern of the plants of the pattern of the plants of the pattern of the plants of the plant on the individual and highly sensitive constitution of the plant in question. It is, of course, true that those who need for mechanical explanations of growth cursuaters might be able to mechanical explanations of growth cursuaters might be able to did such a not for transverse geotropian. But when Frank's acceptable; and, judging from my own experts lead and could that Frank's work descreted to have a powerful effect in pre-paring the minds of physiologuats for a just view of irritability. The builder in transverse geotropian received interesting supporting the minds of physiologuats for a just view of irritability. The builder in transverse geotropian received interesting supporting to the state of the property of the minds of physiologuats for a just view of irritability. The builder in transverse geotropian received interesting supporting to the property of the

undoubtedly right, his views were strongly opposed at the time. He held similar views on the effect of light, believing that the power possessed by leaves of placing themselves at right angles to the direction of incident light must be considered as a new to the direction of incident light must be considered as a new type of helitorype movement; nanwers or diabeliotropism. Frank's views were criticated and opposed by De Vires (Sachis the Witzburg Laboristor), titted to above that Frank's results can be explained without having resort to new types of geo-orholtorpism. De Vires believed, for mistance, that a led' may be apheliotropisc and apogeotropic, and that its horizontal posi-tion under vernell illumination in othe to a balance struck between the opposing tendencies, one of which calls forth an unward, the other a downward curvature

oner a downward curvature.

The same point of view occurs again in Sachs's paper on "Orthotrope and Plagotrope Plant members" (Sachs's Arbeiten, 1879). Sachs holds to the opinion that Frank's theory is untenable, that it is upset by De Vires, and that the oblique on horizontal position is to be explained as the result of a balance

between opposing tendencies
In a paper published the following year, 1880 (Journal Linn
Soc.), I attempted to decide between the opposing views. My Soc.), I attempted to decide between the opposing views. My experiments proved that at least certain leaves can place themselves at right angles to the direction of incident light when there is no possibility of a balance being struck. The outcome of my experiments was to convince me that Frank's views are correct—namely, that the quality of growth called transverse heliotropism does exist.

This view was accepted by my father in the "Power of Move ent." The conclusions of Vochting, in the Bot Zeitung, 1888, and Krabbe in Pringsheim's Juhrbucker, 1889, vol. xx, are on

and Kiabbe in Fringsheim's Tyleheinder, 1880, vol. 2x. ax on the same side of the question the same side of the question of the part of th posts, not as direct causes.

Frank saw clearly that plants may gain such various aptitudes for reacting to light and gravitation as best suit their modes of

In stating this view, he refers to the influence of the "Origin of Species," which had shown how any qualities useful to living things might be developed by natural selection. Fraink described the qualities thus gained under the term fodarity. He supposed that the cell-membranes of a transversely believotopic lest (for instance) were so endowed that a ray of light striking it obinstance, were so encover that a ray or ugit striking it ob-iquely from base to aper produced an increase of growth on the product of the product of the product of the base caused a reverse movement. The polarity-assumption of Frank is a purely gratutions one, and, if strictly interpreted, hardly tends to bring growth-curvatures into harmony with what we know of the relation of life to environment.

It will no doubt appear to be a forcing of evidence if, after such a statement as the last. I still claim for Frank that he led such a statement as the last, I still claim for Frank that he led the way to turn modern were of traibality. I can, of course, only judge of the effect of his writings on myself, and I feel sure that they prepared me to accept the modern view I must also be institled that Frank, in spite of his assumption of polarly, also be institled that Frank, in spite of his assumption of polarly, and different from our of the present odly. Thus, he compares the action of gravitation on plants to the influence of the perception of food on a chicken. He peaks, no, of custom Qurantal Linn. Soc., 1850, p. 94), or use, building up the specialised "matinet" for certain Curvairus. These are expressions consistent with perfectly just in speaking of Frank's belief to different fixeds of principlings, they have followed:

perfectly just in speaking of Frank's belief in different kines or irribablys, although is so judging be may prhaps have followed equity rather than law. One of the whole the perfect of the perfect flamence, and markedly indisenced, by differences in illumina-tion. Please grow more quickly, desires persists, it adukness than in light-. With this fact to go on, it was perfectly natural that sumple mechanical explanations of heliotopolam should be made. De Candolie, as it well known, explained such curves by the none apple growth of the shaded side. Thus it

came about that heliotropism was discassed, for instance, in Sach's "Text-book," cell. 4, 1874, under the same heading as the influence of light on re-tilinear growth. Shorily afterwards, in 1876, a pupil of Sach's—Muller-Thangas—published ("Forn") a research carried out in the Wurtburg Laboratory, which is of some Importance. In the introductory remarks he work — ""It has been hithirts supposed that helications." remarks he wrote — "It has been hills rio supposed usa neutropic curvatures depend on a difference in intensity of illumination on the two side— Sachs came to a different or apinon in his work on geotropism he found himself compelled to believe that in heliotropic, just as in geotropic curvatures, it is not a question of different intensities on opposite sides, but rather that heliotropic effect depends on the direction of the light,"

Muller's research gave weight to this union of geo- and helio-tropic effects by showing a number of resemblances in the tropic effects of showing a number of resemblances in the manner and form of the two curvatures. Again, when it was found that apheliotropic organs are influenced by light and darkness in precisely the same manner as positively heliotropic ones, it became clear that the mechanical explanation of De Candolle was untenable for negatively heliotropic organs, it might still no doubt be upheld for positively heliotropic organs, but, as a matter of fact, it was not so upheld. There was a tendency to unify our view of growth-curvatures, and the union of the two forms of heliotropism gave strength to the movement. Nor was this all , when it became clear that light did not produce heliotropic curvatures by direct mechanical effect, it was natural neitotropic curvatures by direct mechanical enect, it was natural to remember that gravitation has none either, we cannot point to any reason (except the crudest ones) why the lower side of a horizontal root, should grow the faster for the direct effects of gravitation. That being o, light and gravitation ould be classed together as external so, light and gravitation could be classed together as external agencies acting, not directly, but in some unknown indirect manner. I do not imply that such a result followed immediately, but that the line of research above alluded to helped in some degree to lead the way to a belief in growth-curvatures as phenomena of irritability

when my father was writing our book, "The Power of Movement in Plants" (1880), in which he adopted to the fullest extent a belief that growth-curvatures are phenomena of irritability, the only modern statement of such a view which he only, the only modern statement of seem a view within the could find was in a passage by Sach (Arbeiten, i., 1879, p. 282), where he writes that "The living material of plants internally differentiated in such a way that different parts are supplied with specific energies resembling those of the sensory energe (Simietnaryen) of animals. Anisotropy in plants fulfils

the same purpose as do sense perceptions in animals."

The idea of irritability as applied to growth-curvatures is expressed with sufficient clearness in "The Power of Movement." expressed with sametent clearness in "the Fower or move ment." Thus, for the case of goodrop in we wrote [6, 521].—"Different parts or organs on the same plant, and the same part in different species, are this excited to act in a widely different manner. We can see no reason why the attraction of gravity should interedly modify the state of turgetience and ashequent growth of one part, on the tupper side, and of another controlled to the state of turgetience and so the state of turgetience and so the sequent growth of one part, on the tupper side, and of another controlled to the state of turgetience and turgetience and the state of turgetience and geotropic, apogeotropic, and diageotropic movements, the purpose of which we can generally understand, have been acquired for the advantage of the plant by the modification of the ever-present movement of circumnutation. This, however, implies final gravitation produces some effect on the young tissues sufficient to serve as a guide to the plant." A similar view is given for heliotropism. It should be noted that the essence of the view—namely, that light and gravitation act as guides or land-narks by which the plant can direct itself—can be held without a belief in circumnutation.

a belief in circumsutation.

In Feffer's admirable "Planzenphysiologie," 1881, the conception of stimulus and reaction is fully given, and is applied, among other cuest, to that of heliotropism and geotropism Pfeffer states clearly, and without reserve or obscurity, the view that light and grantition cat as attend or releasing forces, in manners decided by the organization of the plant. Pfeffer seems to me to be the first without who has trated the subject.

fully and consistently, In Sachs's "Vorlesungen" (1882), a view similar to that briefly sketched in his paper of 1879 is upheld Geotropism In his "Vorlesungen," p 854, Suchs states that he wrote Müller-

In his "Vorteungen," p. 946, oncore source that the work of Thurgau's involution of Schmitz, Limnaca, 1641; Müller-Thurgau ("Flore," 1876), F. Dorwin, Sachu's Agekrin, 1860. The two latter researches were carried out under the direction of Sachaan his laboratory.

and heliotroptism are described as Resercehasunges, i.e., phenomens of stimulation. The phenomena in question are described under the heading Antiotrops, a word which expresses, exceeding 0 Statis p. 550. The same external forces assure the most varied directions of growth. In another passage (p. 859) he states that the anisotropy of the different organ "in the most varied directions of growth." In another passage (p. 859) he states that the anisotropy of the different organ "in the state of th

physiology.

I cannot, however, omit to mention Pfeffer's (Tubing.n., Untersuchungen, vol. 1) brilliant researches on the chemotaxis Uniterinctuangen, vol. 1) brilliant release on the chemicasis (untability to certain resignits) of low organisms, such as antherozoids and bacteria. To take a single instance, Pfeffer showed that ithe antherozoids, in responding to the effect of make add, follow precisely the same law that in animals corre-tates the attempt of stimulus and amount of effect. Tha result, although it has no direct connection with growth-curvatures, is nevertheless of the highest importance in connection with the

general question of vegetable irritability. general question of vegetable irritations.

Nor can I omit to menuon the ingenious reasoning by which
Noll (Sachs's Arbaten, vol up, 466) localized the seat of irritability in a vegetable cell. He points out how in acellular
plants, such as Caulerpa or Derbesta, the flowing protoplasm may travel from positively geotropic root to apogeotropic stem, may travel from positively georying tool to apageotropic amounts and he argues from this that the motile endopiasm cannot be the eat of specific irritability. The flowing plasma, which is always changing its position with regard to external forces, must be as fully incapacitated from responding to them as though the plant were turning on a kinosiat. It follows from this that it must be the stationary ectoplasm which perceives external change From a different point of view, this is what we should expeci—we should naturally suppose that the part which regu-lates the growth of the membrane, and therefore the curvature of the cell, should be the irritable constituent of the cell

contents of the stabilithment of a stabilithment of

The first step in advance of Holmeister's views was the esta blishment that the curvatures under consideration are due to unequal growth—that is to say, to an excess of longitudinal unequal growth—that is to say, to an excess or longitudinal growth on the concave side. It is not, however, easy to say how far. Hofmester had this idea, for it, in fact, depends on how we define "growth." Hofmester keep, of course, that the convex side of a curved shoot was longer than it had been before the curvature occurred, this is a the concave side increases in length during the curvature occurred. three These permanent elongations he must have known to be growth, but his attention was directed to what it, after all, the more important point-namely, why it was that unequal clonga-

more important point—namely, robylt was that unequal enouga-tion took place.

Sachs, in his "Experimental Physiologie," held that growth-curvatures reducto unequal growth. In his "Text-book" (1874), English translation, 185a, p. 553, the author, referring to Hof-metics" work, say, —"I pointed out that the growth of the mental work of the properties of the properties of the properties of the accelerated, and that of his properties of the accelerated, and that of the upper surface retarded; I did not at the time express an opinion as to whether these modifications of growth were due to an altered dustribution of plantic material of the control of the control of plantic material. The control of the control of plantic material control of the control of the

sharp curve close to the tlp of a geotropic root, and the long searp curve close to the tip of a geotropic root, and the rong gradual curve of an appoetropic shoot, are necessary conse-quences from the manner in which growth and distributed in these parts. He demonstrated that rectlinear growth and geotropic curvature require the same external conditions; that, for instance, a temperature low enough to check growth also puts a

stop to geotropism.

The distribution of longitudinal growth, which produces g Internation of longitudinal growth, which produces geo-tropism, was afterwards studied by Sachs (Arbeiten, 1 p 193, Jane 1871), who thoroughly established the fact that the convex side grows faster, while the concave side grows slower, than if the organ had remsined vertical and uncurved.

the organ had remined vertical and uncurred.

These facts are of interest in themselves, but they do not, any more than Frank's results, touch the root of the matter of the produced by the produced by growth.

The next advance in our knowledge did, in fact, accompany advances a root knowledge did, in fact, accompany advances are not knowledge did in the submitted of produced to the control of provided the produced of the produced by the hydrostatic pressure examing within In a force was at had by which growth could be concerved to be osmosis, which gives the force by which the cells are stretched, as force was at hand by which growth could be conceived to be caused. The first clear definition of turgor, and a statement of its importance for growth, occurs in Sach's classical paper on growth (Arbaten, p. 104, August 1871)

As soon as the importance of turgor in relation to growth was clearly put forward, it was natural that its equal importance with regard to growth curvatures should come to the fore, and with regard to growth on trivatures should come to the fore, and that increased growth on the convex side (leading to curvature) should be put down to increased internal cell-pressure in those trivates. In the fourth edition of Sach's "Lehrbach" (1874), Eng trana, 1882, p 334, such a view is tentatively given, but the author saw very clearly that much more evidence was needed author saw very clearly that much more evidence was needed before anything like a conclusion as to the mechanism of move-ment could be arrived at. The difficulty which faced him was not a new one—in a slightly different form it had occurred to Hofmeister—the question, namely, whether the curvatures of acellular an I multicellular organs depend on the same or on different causes. If one explanation is applicable to both, then omerent causes. It one expinantion is applicable to both, then we must give up as a primary cause any changes in the osmotic force of the cells. For no change in the pressure inside a cell will produce a curvature in that cell, whereas, in a multicellular organ, if in the cells in one longitudinal half an increase of cosmotic substances takes place, so that the cell-walls are subject

to greater stretching force, curvature will take place.
On the other hand, if the cause of bending of acellular and multicellular organs is the same, we must believe that the curva-ture takes its origin in changes in the cell-walls. In an accludature takes its origin in changes in the centwants. In an accounts organ, if the cell-membranes yield symmetrically to internal pre-sure, growth will be in a straight line; if it yields asymmetrically it will curve Thus, if the membrane along one side of a cell becomes more or less rest-ting than the rest of the membrane, a curvature will result

memorane, a curvature wair reasu; If we are to apply strictly the same principle to accillular and multicellular organs, we must suppose that the whole organ curves, because each individual cell behaves the one of the above-described free cells, the curvature of the whole resulting from the sum of the curves of the separate cells. This was Frank's view, and it also occur in Sach's "Tear-book" (1879.)

Eng trans., 1882, p. 842. re we bound to believe that the mechanism of acellular and Are we bound to believe that the mechanism of acellular and multicellular curvatures is so strictly dentical as Frank supposed? In the first place, it is not clear why there should be thenlity of mechanism in the movements of organs or plants of completely different types of structure. The upholders of the

completely different types of structure. The combination of the completely different types of structure. The combination caphanido must apply to both cases. I believe that light may be thrown on the matter by condicing turquescee, not may be thrown on the matter by condicing turquescee, not may be through the complete that the combination of the properties of the combination of the properties of the combination of the properties of the combination of the combinatio

by the cell wall in one case is carried out by cortical tissues in the other If this is the case for one function, there is no reason why is should not hold good in another, viz the machinery of movement.

If we hold this view that the cortex in one case is analogous with a simple membrane in the other, we shall not translate the unity of accilular and multiccilular organs so strictly as did Frank Indeed, we may fairly consider it harmonious with our knowledge in other departments to find similar functions per-formed by morphologically different parts. The cortex of a geotropic shoot would thus be analogous with the membrane of a geotropic cell in regard to movement, just as we know that these parts are anniogous in regard to stability.

In spite of the difficulties sketched above, one writer of the

first rank, namely, H de Vries, has upheld the view that growth curvatures in multicellular organs (Bet Lutung, 1879, p. 835), curvatures in multicellular organs (Irel Zeitung, 1879, p. 858), are that to increased cell-prevaue on the convex safe, the rease of annote sub-stances in the cell-cap of per down increase of cannote sub-stances in the cell-cap of per down increase of cannote sub-stances in the cell-cap of per down increases of cannote sub-flowed naturally from De Vries's interesting plasmolytic work (label 1877, p. 1). He had shown that those sections of a targe-cent short which were in most rapid growth show the targe-cent shoot which were in most rapid grown show use greatest amount of shortening when targescence is removed by plas-molysts. This was supposed to show that growth is proportional to the stretching or elongation of the cell-walls by turgor. Growth, according to this view, consists of two processes (1) of a tem porray elongation due to turgescence, and (2) of a high procesby which the elongation is residered permanent. De Vies assumed that where the elongation occurred, its amount must be proportional to the osmotic activity of the cell contents, thus neglecting the other factor in the problem-namely, the variability in the resistance of the membranes. He applied the He applied the ability in the resistance of the membranes. He applied the plasmolytic method to growth-curvatures, and made the same deductions. He found that a curved organ shows a flatter curve farte being plasmolytes and This, according to his previous argument, shows that the cell-sap on the convex is more powerfully connote; than that on the concave side. This again leads to

fully ownotic than that on the concave since I mis again remore to increased cloth-stretching, and finally to increased growth. The most serious objection to De Vries's views is that the convex half of a curving organ does not contain a greater amount of osmotically active suistance. It must, however, he noted in of osmotically active suissance. It must, nowever, we now in the heliotropic and gootropic curvature of pulyini, there is an osmotic difference between the two halves 4-so that, if the argument from uniformity is used against De Vries (in the matter of accellular and multicellular organs), it may fairly be used in his favour as regards the comparison of curvatures produced with and without pulvini

It is not easy to determine the extent to which De Vries's views It is not etsy to electrimise the extent to which he is in extent to on the mechanics of growth curvature were accepted. The point, however, is of no great importance, for the current of conviction soon began to run in an opposite direction. "acks ("Lehrbuch," ed 4, Eng trans p 835) had already pointed out that attentions abould be directed to change in

extensibility of cell-walls as an important factor in the problem Wiesner, in his "Heliotropische Erscheinungen" (I unit Misser), vol. lxxxi, 1880, p. 7, also in the Denkschriften, 1882), held that the curvature of multicellular organs is due both to an increase of osmotic force on the convex side, and to in-creased ductility of the membranes of the same part. He creased ductility* of the membranes of the same part. He repeated De Vrne's plasmolynic experiments, and mode out the currons fact that in many cases the curvature is increased instead of being dimmashed. He attributed the result to the concave tissues, being more perfectly elastic than ductile convex tissues, so that when turgescence is removed, the more clastic tissues.

shorten most, and, by diminishing the length of the concave side, increase the curvature.

Strasburger, in his "Zellhaute" (1882), suggested that growthcurvatures are due to increased ductility of the convex membranes, and gave a number of instances to prove that a change to a ductile condition does occur in other physiological processe such as the stretching of the cellulose ring in (1, togonium to a

Frank made similar experiments, but failed to find any diminution of

412

uniform thin membrane, the branching of Cladophora, and the excape of sexual products in certain Alge.

We now pass on to the work of two observers, Wortmann and Noll, who have devoted special attention to mechanism of curvature of acciliust and multicellular organs must have a saumption, altered several times mentioned, that the growth-curvature of acciliust and multicellular organs must have a common cause. He began by tending Kohl's statement (Ret. Hight, Marburg, Field's (I have not seen Kohl's paper) that when the concave wail. Wortmann principally investigated the curvature decovered in Phytomyces by Erres (Ret. Zeitzurg, 1884) which can be profined by contact. When the hypha is toched with a plant filtered or worth a plantum wire, or by allowing a speck side. The hypha is so highly sensitive to contact that it curves in from three to sum mininte; it is clearly a growth-curvature, a toched visited. sion. In the pyper as so nighty sensitive to contact that it curves in from three to sat minners; in a clearly a growth-curvature, curvatures thus produced, as well as in apogentropic and helicotropic curvatures, the accumulation of protopiatum on the concave side is, according to Wortmann, clearly visible, and, what is more important, the membrane becomes thicker on the want is more important, the membrane becomes thicker on the concave side, sometimes twice as thick as on the opposite side of the cell. In consequence of the unequal thickening of the membranes, the cell is supposed to yield asymmetrically cell-pressure, and the necessary consequence is that the cell grows into a curved form.

In applying the same method of investigation to multicellular arts, Wortmann followed Ciestelski (Cohu's "Beltrage," 1872, parts, Wortmann followed Ciesielaki (Cohu's "Beltrage," 1872, p. 1; who noticed that in geotropically curved roots the cells of the concave (lower) side of the organ are much more densely filled with protoplasm than are the convex cells. Sachi ("Vorlesmigen," p. 842) describes a similar state of things in the halms of grasses, and Kohl, agam, in tendrals and the stems of climbing plants.

Wortmann first of all made sure that no redistribution of prote Worfmann first of all made sure that no requirement on proto-plant mould be observed in the individual cells of curving multi-cellinar organs. If each cell behaved independently like a free cell, we might expect to find a collection of protoplasm on the concave wall of all the constituent cells of a curving shoot. But this is not the case. Nor at first could any microscopie differences be made out between the concave and convex tiss of a curving shoot. But when the stimulus was made to act for of a curving about. But when the stimulus was made to act for a long time, differences were apparent. A young Thaseolus are also as the property of the property of the story the tissues was visible The cells of the cortex on the upper side became densely filled with protoplasm, while the lower cor-tical cells were relatively poor in protoplasmic contents. The same changes in the membranes occur as those noticed in Phy-comyoss—that is to say, the walls of the cortex on the upper side are very much thicker than those on the lower side.¹

Since the walls of the cortical cells have become more resisting on the upper than on the lower side, then (assuming the osmotic expanding force to be the same in both cases) the growth will be quicker on the lower side, and the shoot will curve upwards. Wortmann states that his observations account for the fact that the convex side grows quicker, not merely than the concave, but than a normal nubent shoot. But he does not seem to have compared the thickness of the convex cell walls with the normal, although he states that they are poorer in protoplasm than is usual, and from this it may, according to his views, be perhaps med that the membrages are abnormally thin,

Wortmann points out that his views account for two well known features in growth-curvatures, viz. the latest period and the after effect. If a curvature can only occur when a difference in structure of cell-walls has arisen, it is certainly natural that some time should occur before the curvature is apparent. I do not lay much stress on this part of the subject, as I feel sure the whole question of latent period needs further investigation With regard to after-effect it is true that Wortmann's views account for the continuance of curvature after the stimulus has ceased to act.

Wortmann attaches great importance to another point in his Both protoplasmic change and thickening of cell-walls occur to some ex-

theory, which, could it be established, would be of the greatest interest, and would unlie under a common point of view, not only acciliate and multicellate organs, but also nated protoplasm, e.g. the plasmodus of myxomytetes. The wew in other constructions are constructed by the construction was testinizely suggested by Seath, "Lichtonic," 1874; physiologie," ii p. 331) he a similar sprint. The apogeotropic curvature of a Physomogree-hybal is supposed to be due to the unequal theckening of the membrane on the upper and ol lower than the construction of a physomogree-hybal is supposed to be due to the unequal theckening of the membrane on the upper and ol lower than the lower to the upper and of the Coll. In the same way in a multicellular organ the protoplasm is supposed to migrate from the lower to the upper and of the Coll. In the same way in a multicellular organ the protoplasm he spope cortex and pith to the upper cortex and pith to the apogeotropian of a cell or a multicellular part would be due to the spogeotropian or tendency to migrate vertically upward of the protoplasm. There are great difficulties in the way of a curved Physomogres-hybal, unwhich protoplasm has accumulate an extra constitution of the protoplasm. There are great difficulties in the way of a curved Physomogres-hybal, unwhich that is Nitelia and in Bryonathe carculating protoplasm continues in movement, and done accumulate in any part of the cell. Lastly, there seems and in Bryonathe carculating protoplasm continues in movement, and done expected. Morrover, he points of that is Nitelia and in Bryonathe carculating protoplasm continues in movement, and done expected. Morrover, he points of that is Nitelia and in Bryonathe carculating protoplasm continues in movement, and done accumulate in any part of the cell. Lastly, there seems and part of the cell. Wertimen's local protoplasm continues of the cell work of the part theory, which, could it be established, would be of the greatest

changes are the result aut not the cause of the curvature. Living also produced curvature in Phaseois by bending the aparting also produced curvature in Phaseois by bending the apartines of the produced by is a result, do of curvature, but of strain mechanically produced When a plant is prevented from executing an apogeotropic movement it is clear that a longitudinal strain is put on the upper (concave) side. But the longitudinal strain in Elfving's plants so on the convex side. Therefore, if, as Elfving believes, the visible changes are due to strain, they should, as they do, occur on the convex side in his experiments, on the concave in

Wormann's replied in the Bot. Zatung, 1888, p. 469, and at-tempted to explain how Elfving's results might be explained and yet his own theory hold good. The reply is by no means so strong as the criticism, and it must be allowed that Elfving has

strong as the criticism, and it must be allowed that Elfving has estimated with workensam's argument and the No. 18 control of the N

Noli further points out what is undoubtedly a fault in worn-manu's theory—namely, that he explains the retardation on the concave rather than acceleration on the convex side. This crit-cism is only partially just, for though Wortmann's description only shows a relative thinness of the walls on the convex side, yet it is clear he believed there to be an absolute diminition of

yet it a clear he believed there to be an absolute diminution of resisting power on that side. No'll's experiments with grass halms show clearly that accelera-tion of growth on the convex and is the primary change, rather than retartation along the concave half. When the halms are fixed in horizontal glass tables, so that they are situatised but unable to bend, the lower half of the pulvinus forms an irregular ourgrowth, increasing radially since it is not able to linewas longitudinally.

A similar argument may be drawn from Elfring's experiments. He found that the pulvini of grass halms placed on the kinnostat increase in length. This experiment shows incidentally that the kilnostat does not remove but merely distribute equally the geokilhoutst does not remove but merely distribute equally the goo-tropic similars; as thos that geotropic strimbute leads to increased, not to diminished growth. The same thing is proved by the simple fact that a grass halm shows no growth in its pulvinas while it is vertical, so that when curvature begins (on its being placed horigonist); it must be due to acceleration on the convex, since there is no growth on the concave side in which retardation could occur. Notify wive a that the primary change as an increase in extensibility of the tissues on the convex side. view he proceeded to test experimentally. A growing shoot was fixed in a vertical position, and a certain bending force was applied to make it curve out of the vertical, first to the right and then to the left. If the cortical tissues are, at the beginning of the experiment, equally resisting all round, it is clear that the excursions from the vertical to the right and left will be equal excursions from the vertical to fie right and left will be equal As a matter of fixet the occasions to the right and left were the state of the control of the right and left were to the subsequent result. The shoot was then placed horna-tally until getorijo or other curvature was just beginning, when the above bending experiment was repeated. It was then found the shown bending experiment was repeated. It was then found the excursion was greater than it had been In the five experi-ments given by Noll the excursion in the opposite direction stretching of the concave side was less than it had been, and (stretching of the concave side) was less than it had been, and the state that all the other experiments showed a similar result. The increased extensibility of the convex side as clearly the most striking part of the phenomenon, but I fail to see why Noll Takes as the property of the and the curvature were due to discrence in osmoit force on the convex and concave sides, the shoot would react differently in the two directions; for Instance, the concave side would be more easily compressed. Noil and Wormsan's explanations differ in this: the former lays the greater stress on the increased extensibility of the convex side, the latter on the dimination of that of the concave side. Again, Wortmann explains the dif-ference in extensibility as due to differences in thickness of the cell-walls. Noll gives no mechanical explanation, but assumes that the ectoplasm has the power of producing changes in the quality of the cell-wall in some unknown way.

quality of the cell-wall in some unknown way.

In the early sages of curvature, a phenomenon takes place to
which Noll attaches great importance as supporting his view.
When a curved organ is plasmolyzed, it suffers a dimmution of
curvature, as De Vries showed, but Noll i has proved that in the curvatine, as De vice showed, but not in any phorea use in use early stage of curvature a contrary movement occurs—that is to say, the curvature is increased. This seems to show that the yielding of the convex sets so wing to a dettility, which prevents its holding its own against the more perfect elasticity of the conteave sets of but this is only the beginning of the phenomenon; as the plasmolyzing agent continues to act, a reverse movement takes place, the well-known flattening of the curva-ture described by De Vries. It is to me incomprehensible how in a given condition of cell-walls these results can occur in dif-ferent stages of plasmolysis. I can understand one occurring when the curvature is recent, and the other, the flattening of the curve, occurring when the ductile convex parts have reacquired elasticity. The fact undoubtedly is as Noll describes it his

explanation seems to me inadequate

We have now seen that the most acceptable theory of the
machinery of these curvatures is in its main features akin to Hofmeister's, the power of elongation supplying the motive force, while the varying extensibility of the membranes determines the nature and direction of the bend.

nature and decition of the bend.
The question now arises: It it possible by these means to
The question now arises the state of the control of the
theory for which there is most to be said on experimental
grounds—vis. No!!—it will be noted that it is essentially connected with the decrine of growth by apposition. The question,
neeted with the decrine of growth by apposition. The question,
for the phenomens of ordinary growth, may be applied suitedir
metandar to growth curvature. This doctrine in ats original
purity absolutely requires turgescence to account for the clongspurity absolutely requires turgescence to account for the clongs-* The similar results obtained by Wlasner are noticed above

NO. 1130. VOL. 44]

tion of growth. The older layers, separated from the ectoplasm by the younger layers of cell-wall, can only be elongated by traction. Growth by intussusception does not absolutely retraction. Growth by intussusception does not absolutely require this force; the theory that the micellee are separated by traction, and thus allow intercalation of fresh micellee, is a view for which Sachs is chiefly responsible

for which seems is enterly responsible. Since surface growth by apposition is absolutely dependent on the traction exercised by cell-pressure, it is a fair question—how fair growth is influenced by foreithe clongstion. Baranetshy ($Alim \ Acad. St \ Ptt., v. vol \ xxviv p. 20)$ states that when a plant is subject to traction, as by even a small weight attached to the free end, the rate of growth is lowered. Almoran (Pringsheim 2, Aurher), axis, less a Limmentann points out in the same connection, found no increased elongation of collenchyma when stretched for some days by means of a weight A greater difficulty is that growth may be absolutely and at once stopped difficulty is that growth may be absolutely and at once stopped to by placing the growing organ in an atmosphere free from oxygen apparently does not dimunch targeteene, yet growth atons, the collection as uncreasing in length by mechanical stretch-ing, and if the turger is not interfered with, increase in length ought to continue. The same thing applies to curvatures upon the continue of the co concave, turgescence, as far as we know, continues, yet no after-effect is observed. The same result may be gathered from concave, turgescence, as her as we know, continues, yet no affect concave, turgescence, as her as we know, continues, yet no affect Adheasays's lineteresting experiments on the growth of roots, He showed that lowering the temperature has an almost instances lathburst effect on growth. Thus maste roots (at a micrometer per hour, were placed in water at \$\cdot\), and absolutely no growth occurred during the following ten minutes, in which the thermometer rose to 6'c; Thiresual is all the nove-valuable to the state of the plant of the plant of the state of the actual to the plantopict chortening, is about the same whether the root is in full growth or not growing at all. This is a estimated by plantopicts chortening, is about the same whether the root in full growth or not growing at all. This is a conclusive, for it the growing cell-walls were facultie they the non-growing cells might shorten a good deal, owing to their more perfect cleanting; \(^1\) therefore Aukensay's plasmolytic results are not in this particular connection of great importance, creatly are not in this particular connection of great importance, creatly are not in the particular connection of great importance, creatly are not in the particular connection of great importance, creatly is

except as showing that the non-growing roots were certainly to some extent turgeteent. There are other facts which make it extremely difficult to understand how surface-growing can depend on cell-pressure Nageh ("Starkehorner," p 379) pointed out that the growth of syndiciated rely such colorage commonly to those being out-significations of the surface and the surface of the surface of the surface of the surface and the surface of the s An intermodal feel of Nitella increases to 2000 times its original heigh, while it only becomes ten times as wide as it was at fact. The name of the control of the control

tion remains a problem for those who occure in some growing by apposition.

The point of special interest is that differences in extensibility and different differed one cannot be supposed to exist in a homogeneous membrane. If any purely physical characters can be applied to the control of the control of

^{*}Dentek Bet. Grs., 1800, p. 61. The paper contains an excellent discussion on the mechanics of growth, to which I am much indebted "Life, et P. 1878, Act P. 1878, T. 288, vol. 1872; T.

Such structural differences do, of course, exist, but whether they are unficient to account for the phenomena is different question. Straburger ("Zellhaute," p. 164) supposes that the elatibity of a cell-wall depends on the lest-formed layers, and as in these the microsomes are seen arranging themselves in lines or patterns, we have a heterogeneity of structure which may or may not be sufficient.

414

not be summent. We have now seen that it is difficult to believe, although it is not inconceivable, that the extending force of cell-urgor, combined with differences in extensibility of the membranes (depending on structural characters), may account for the phenomena of rectulinear growth. But, even if we allow that this is so, how are we to apply the same explanation to growthcurvatures? How are we to account for the rapid changes in extensibility necessary to produce geotropic or heliotropic curva-tures? The influences which Strasburger and Noll suppose 10 act on the cell-walls and render them ductile cannot account for act on the ceri-walls and render them duettle cannot account for settensibility non-direction only. Nor does Wortmann's theory, that difference in extensibility depends on difference in thek-ness, meet the case completely. What we used is an increase in longuidual, not in general extensibility. I presume that theogenization might say that the excess in longuidual extensibility is always present whether geoeral extensibility is greater or less. In the meanwhile we must pass on to more recent

or less In the meanwhile we must pass on to more recent researches on surface-growth by apposition. In Strasburger's later work ("Histologusche Bedrage," 1889), his views on growth have undergone c-naiderable modification. The study of certain epidermic cells, of the folds in membranes, and the repetition of Krabbe's work on certain bast fibres, have and the repetition of Krabbe's work on certain bast fibres, have convinced burn that appointion does not account for all forms of goowth. Krabbe (Fringithem's Jake's, xmr) showed that in without any sixth amount of thinning in the membrance as would occur if the bulging were due to stretching. The only possible explanation seems to be that there is a migration of new material into the cell-wall. Such intustiception might be, as Neget supposed, a flow of fland out of which new miteellie crystallize; but it is now established that cellulose arises as a crystalisate; but it is now established that cellulose anset as a modification of protoplasm, so that it would harmonize with our Poowledge of the origin of cellulose if we assume that intussacterion was preceded by a wandering of protoplasm into the cell-wall. Such a state of things would render possible the regulation of longitudinal growth in the case of Nitella and Spirogras, already alluded to, as well as in growth curvatures. This view might also harmonize with Weisner's theory (Sixt.)

This view might also harmonize with Wiesner's theory (size, Wien Adad, 1885, vol. xon; p 17) that the cell-wall contains protoplasm as long as it continues to grow. For the sake of brevity! content myself with the above examples: I think it will be allowed that there is a focussing of speculation from many adds in favour of "active" surface-growth -or, what is perhaps a better way of putting it, in favour of a belief that the extension of cell membranes depends on physiological rather than physical properties, that it is in some way under the immediate control of the protoplasm. We may take our choice between Wiesner's wall-protoplasm (dermatoplasm), protoplasmic intussusception as conceived by Strasburger, or the action of the ectoplasm in the manner suggested by Vines, who action of the ectoplasm in the manner suggested by vines, who supposes that the crucial point is a change in the motility of the protoplasm, not of the cell membrane. The latter theory would unidoubtedly meet the difficulties—if we could believe that so yielding a substance as protoplasm could resist the force of

ourgor.

The great difficulty is, as it seems to me, that since, e.g. in

Caulerpa, surface-growth is clearly due to stretching, as Noll has

an end since in camotic cell-pressure a stretching force does exist, it cannot be doubted that tungor, and ordinary physical extensibility are conditions of the problem. This remains true in spite of Klebs's (Tubingen Untersuchungen, it p 489) curious observations on the growth of plasmolyzed Algae, or 499) curious observations on the growin of plasmostzed raige, or in spite of the fact that pollen tubes may grow without tunger, in spite of the fact that pollen tubes may grow without tunger, in spite of the same being perhaps true of young cells filled with portoplasm (see Noll, Wurthung Arbeiten, ni. p 530). In the face of all these facts, osmotic pressure in the cell must remain a vera causa tending to surface growth.

If we accept some form of "active" surface growth, we must

' Sachi's 4 riesten, 15/2, and "Physiology," 1886 See also Gardiner, on protoplasmic crimtechtity in the Janual of Botany, i p. 366 Pfeiffer has think, shown the Viners and Gardiner's thorses assume the estience of to great aircraft in the exceptasm See Pfeiffer in Abhandl der k Sacks. NO. 1130, VOL. 44]

deal with turgor in another way, although to do so may require a violent exercise of the imagination. Are we to believe, for instance, that the function of turgescence is the attaining of mechanical strength? If we hold that cell-walls increase in area mechanical strength? If we hold that cell-walls increase in area independently of turgor, we shall be forced to invent a hypothesis such as the following—which I am far from intending to uphold. It is possible to imagine that the function of the force of turgor is It is possible to imagine that the function of the force of turgor is morely to spread out the growing membrane to its full extent, and, as it were, but the control of the function of the fu by turgor (as in Mucor), instead of by brute strength of material, as in a tree-trunk, a great economy in cellulose is effected. If turgor played our hypothetical part of smoothing out the mem-brane and insuring that it shall occupy as large a space as possible, it would effect the same kind of economy.

position, it would effect the same kind of economy.

It is not necessary to inquire how far this hypothesis accords with our knowledge of cell mechanics. It is only put forth as an example of the difficulties in which we land if we seek for a new function for turgor. We are, indeed, surrounded by an example of the difficulties in which we land it we seek for a new function for turgor. We are, indeed, surrounded by difficulties; for, though the theories which are classed together as protoplasmic have much in their favour, they, too, lead us into an impasse.

Circumnulation.

I shall conclude by saying a few words about the theory o growth curvatures put forward in the "Power of Movement in Plants." I can here do no more than discuss the relation of circumputation to curvature, which is the thesis of the book in question, without attempting to enter the arena with regard to the many objections which have been raised to other parts of our

A distinguished botanist, Prof Wiesner, of Vienna, published in 1881 a book. "Das Bewegungsvermogen der Pflanzen," entirely devoted to a criticism of the "Power of Movement" emirety services to a criticism of the "Fower of Movement" (p. 8). It is founded on a long seriae of experiments, and is written throughout in a spirit of fabrices and candour which gives it value, apart from its scientific seclelince, as a model of scientific criticism. The words written on the tule-page of the copy, presented to my father are characteristics of the tone of copy pretented to my nature are characteristic of the tone of the book "In gertueur Opposition, aber in unwandelbaret Verchrung," A letter printed among my father's correspondence shows how warmly he appreciated his opponen's attack both as to matter and manner. Wesner's opposition is far-teaching, and includes the chief theoretical conclusion of the book and includes the Chief Incoretical conclusion of the book— namely, that movements such as heliotropism and geotropism are modifications of carcumatustion. Neither will be allow that this revolving nuttion is the widely-speeal phenomenon we held it to be According to Wiester, many parts of plants which do not circumsuate are capable of curving geotropically, &c., he is, therefore, perfectly justified, from his own point of view, in refuting to believe that such curvatures are derivations. from circumnutation He points out that our method of observing circumnutation is inaccurate, inasmuch as the movement is recorded in oblique projection. This we were aware of, and I recorded in oblique projection. This we were aware of, and I cannot but think that Wiesner has unintentionally exaggerated cannot but think that whether has uninenhally exagerated the inaccuracy, and that, if used with rea-onable discretion, it cannot lead to anything like such faulty records as in the suppositious eases given by our critic. However this may be, Wissner's results are perhaps more trustworthy than ours, and should roceive the most careful consideration

Wiesner's conclusions, taken from his own summaries, are as follows :---

The movement described as circumnutation is not a widespread phenomen in in plants. Stems, leaves, and acciliate fungi are to be found which grow in a perfectly straight line. Some roots grow for considerable periods of time without deviating from the vertical. When circumnutation does occur,

derating from the vertical. When circumputation does occur, it cannot be confideded to have the significance given to it in the "Power of Movement". The movement observed by Wiesser 1. As the expression of a certain irregularily in growth depending on the want of absolute symmetry in structure, and on the fact, that the component cells of the organ have not called the component cells of the organ have not called the component cells of the organ have not called the component cells of the organ have not certain organs have inherent tendendies to curve in definite plants—for instance, the benefiting of the hypocotyl in the plant of the component cells of the component of the plants—for instance, the benefiting of the hypocotyl in the plant of the component of the combined with others-heliotropic, geotropic, &c .- lead to

alternate bendings in opposite directions, according as one or other of the components is temporarily the stronger. iii. Wiesner allows that circumnutation does exist in some

in. Wrether allows that circumnutation does exist in some cases. This last class he considers a small one, he states, indeed, that "nearly all, especially the clearly perceptible circumnutations," are combined movements belonging to the second of the above estegories

Although I have perhaps no right to such an opinion without peating Wlesner's work, yet I must confess that I cannot give repeating Wlesner's work, yet I must confess that I cannot give up the bellef that circumputation is a widely-spread phenomenon,

even though it may not be so general as we supposed.

If, then, circumputation is of any importance, we are forced to ask what is its relation to growth-curvatures. It was considered by my father to be "the basis or groundwork for the acquireby my latter to be "the basis or groundwork for the acquire-ment, according to the requirements of the plant, of the most diversified movements" ("Power of Movement," p. 3) He also wrote (loc. cit., p. 4) -- "A considerable difficulty in the also wrote (ec. cit., p 4) — A considerable difficulty as the way of evolution is in part removed, for it might be asked how ind all these diversified movements . first arise? As the case stands, we know that there is always movement in progress, and its simplified, direction, or both, have only to be modified. for the good of the plant in relation to internal or external

Those who have no belief in the importance of circumnutatio and who hold that movements may have arisen without any such basis, may doubtless be justified in their position. I quite agree that movement might be developed without circumnutation having anything to do with the matter. But in seeking the origin of growth-curvatures it is surely rational to look for a ongin or grown-curvatures it surery random to look to a widely-spread movement existing in varying degree: This, as I believe, we have in circumputation and here comes in what seems to me to be characteristic of the evolution of a quality such as movement. In the evolution of structure, each indiwidual represents merely a single one of the units on which selection acts. But an individual which executes a number of selection acts. Dut an individual which executes a number or movements (which may be purposeless) supplies in itself the material out of which warious adapted movements may arise I do not wish to imply that tentative movements are of the same

I do no! with to imply that tentative movements are of the same order of importance as avariations, but they are undoubtedly of the problem may be taken back a stage further, we may ask why erroumulation should exist. In the "Power of Movement" (p. 546) we wrote—"Why every part of a plant whits it is growing, and in some cases after growth has cessed, should have its cells rendered more turgescent and its cell-walls more nave its delit rendered more lurgescent and its cell-walls more extensille first on one side them on another. Is not known of rest." Such periods of comparative rest are fairly harmonious with any theory of growth; it is quite concernable by intussis-ceptionists and appositionists alike that the two stages of elonga-tion and fixation should go on alternately. but this would not tion and fixation should go on alternately. but this would not not not not consume the of to circumstation. It might simply result in a confused struggle of cells, in some of which extension, in other and the confusion, was in the ascendant; but such a plan would be an about the confusion of th tion.2 Whether or no any such origin of circumnutation as is here sketched may be conceived, there can be no doubt that it

here aktched may be conceived, there can be no doubt that it had its origin in the laws of growth apart from its possible had its origin in the laws of growth apart from its spossible and its origin in the laws of growth apart from the law of the law of

NO. 1130, VOL. 441

such a power is nothing more than the heredity, which modifi-the embryo into the literates of its parent, and by a similar power massis that the shoot or root shall take on the straight form necessary to its specific character. But the two cases are not identical. The essence of rectipitality is the power of recovering from disturbance caused by external circumstance. When an organ has been growing more quickly on one side than another, the regulating power reverses this state of things and another, the regulating power reverses this state of things and brings the currying organ back towards the starting-point. We have the properties of the properties of the properties of the have the properties of the probable to ranging a type of trafti-ability which would insure growth being absolutely straight, but it is far more easy to conceive growth as normally made up-of slight departures from a straight line, constantly corrected In drawing a line with a pencil, or in walking towards a given point, we execute an approximately straight line by a series of point, we execute an approximately straight line by a series of corrections, If we may judge in such a nanner by our own experience.

If we may judge in such a nanner by our own experience, the such as the such know from experiments that a power exists of correcting excessive unlateral growth artificially produced, is it not probable that normal growth is similarly kept in an approximately straight line by a series of aberrations and corrections? If this is so circumuutation and rectipetality would be different aspects of

curcumutation and rectipetality would be different superes of the same thing when one interesting corollary is 7 we fix our attention on the regulating power instead of on the visible departures from the straight line, it is clear that we can imagine an irritability to internal growth-changes ensiting in varying the straight line would be corrected. With a lower trimbility the abternations would be greater before they are corrected. In one case the voluble movement of circumunitation would be very one case the visible movement of circumnulation would be very small, in the other case large, but the two processes would be the same. The small irregular lateral curvatures which Wiesner allows to exist would therefore be practically of the same value as regular circumnulation, which be considers comparatively

rare relation between rectipitality and circumnutution may be complified by an illustration which have conclusion and size of in lecturing on this point. A skild beyele rider runs very straight, the deviations from the desired course are comparatively small, whereas a beginner "wobbles" or deviates much But the deviations are of the same nature, both are symptoms of the regulating power of the rider

We may carry the analogy one step further just as growth curvature is the continuance or exaggeration of a nutation in a

we may cary too analogy one step turner just as growth curvature in the communities or seaggeration of a nutation in a so by will exaggeration of a "wobble". It may be said that curcumstations is here redeced to the rank of an accidental deviation from the right line. But this does not seem necessary, the texas. A beyele campo the reiden at allowed his wheel to run into a frozen rut. In the same way it is possible that some degree of curvam nation to correlated with growth in the manner suggested above, owing to the need of regular passes flag growth. Recupratily would than the a power and the same way it is not to be a power of the same way it is not to be a power of the same way it is not to be a power of the same way to be a same way to way to be a same way

Luchman and Franch read a note and exhibated the skin of a tree-clubman kangawo from Northern Queensland, new to science, to which they gave the anne of Denderdagus muellers. This remarkable marsuplal has a body about two feet in length, with a tail somewhat exceeding two feet. The dispreporation between the fore leng and the hind leng is not nearly so great as that of the ordinary the support of the section o

IN his letter on "Dredging Products" (NATURE, August 23, p. 344). Mr. Alez Meek, writing from Sheland, gave a short **rimust of localities where Actinotrochs has been found, at the south coast of England was not mentifloned, Mr. W. L. Calderwood writes to call attention to a paper by his prodecessor at the M.B.A. Laboratory, Plymouth, Mr. G. C. Bourne, published to the Journal of the Marine Biological Association, vol. 1, No. 1. After mentioning the cocurrence of Tornaria, Mr. Bourne goes on to say —"Actinotrocha, the larva of Phoronia, is common. . . Several specimens of Jarral Amphicosis were taken in the tow-net towards the end of October." Invol. in. No. 1, Mr. Garatang also has a note on the coocurrence of the adult Phoronia. Actinotrocha has again appeared several times during the present summer.

M IMPELD, the Swiss engineer, who has been engaged to examine the nature of the summit of Mont Blanc for the construction there of M. Janssen's proposed Observatory, recounts in a Zurich journal the difficulties he is experiencing in his preliminary survey M. Imfeld is staying with eight workmen and two doctors at M. Vallot's Observatory, which has an altitude of 4400 metres, and thence they proceed daily to the summit, where they work for several hours a day in the endeavour to ascertain the depth of the snow for the purpose of getting the necessary foundation for the building M Eiffel has expressed the opinion that the construction of an Observatory will only be possible if the snow does not exceed a depth of 12 metres. M. Imfeld states that they have encountered traces of a ridge of rock 18 to 20 metres below the summit, and covered with about a metre of snow They have therefore commenced to make a series of lateral tunnels on three sides, at a distance equal to 12 metres below the summit, to ascertain if the ridge extends to that height. Progress is necessarily slow. Most of the men are suffering from mal de montagne Some, however, who are engaged at M Vallot's cabin are able to work almost as long as in the valley, and they also eat and sleep well. In spite of two coke stoves, the thermometer of the cabin never rises above zero; even ink freezes, and water bolls at 82°, and they cannot properly cook meat. For a day or two they were disturbed by violent storms.

MARTINIOUR has been visited by a terrible cyclone, the most volcent that has been known in the island since 1817. It lasted four boars, and was followed by an earthquake; and many lives were lost. According to the latest information received in Paris on Martinique on Monday hast, the number of persons known to have persished was 340 but that did not londed the sailors to have persished was 340 but that did not londed the sailor to have persished was 340 but that did not londed the sailor the number of persons known to have persished was 340 but the did not londed the sailor to have been sail to have

completely demolished. The town of Morne Ronge is said to be a total wreck, and Fort de France is almost entirely destroyed. Much suffering prevails among the population.

MESSER, L. REEVEAND CO. have in preparation a new work on the British Fangi, Phycomycles, and Utilingiene, by George Massee, Lecturer on Botany for the London Society for the Extension of University Texaching; a work on the British Heuughers. Heteropters, by Edward Saunders; a new work on the Lepsdopters of the British Islands, by Charles C. Barrett; and a new work on the physiology of the Invertebrats, by Dr. A. B. Griffishs.

MESSRS. WHITTAKER AND Co. are about to publish "A First Book of Electricity and Magnetism," by W. Perren Maycock. The work is intended for the use of elementary science and art and engineering students, and general readers.

MESSES. CASSELL AND Co. are issuing, in monthly parts, a new and revised edition of Sir R. Stawell Ball's well-known "Story of the Heavens" The first part has just been published, THE additions to the Zoological Society's Gardens during the past week include a Common Fox (Canss vulpes), British, pre sented by Captain H. S. Tunnard : five White-eared Conures (Conurus leucotis) from Brazil, presented by Mrs. Arthur Smithers : four Leopard Tortoises (Testudo pardalis), three Angulated Tortolses (Chersina angulata), a Galeated Pentonyx (Pelomedusa paleata), a Hoary Snake (Coronella cana), a Robben Island Snake (Coronella phocarum) from South Africa, presented by the Rev. G. H R. Fisk, C.M.Z S , two Alligators (Alligator mississippiensis) from Carolina, presented by Mr. Charles Downs, a Gold Pheasant (Thaumales picts 9) from China, presented by Mr. R. THURSDAY, SEPTEMBER 3, 1891.

THE REPORT OF THE BOARD OF TRADE COMMITTEE ON ELECTRICAL STANDARDS.

ARDILY, and in a somewhat piecemeal if not grudging fashion, some small provision has been made by Her Majesty's Government for the regulation, under the Board of Trade, of the new but vigorous and rapidly-extending industry which recent developments of electrical science have brought into existence. In no previously-existing branch of trade has the problem of settling standards of measurement been so difficult of solution, and in no other has the problem been so completely solved without trouble, expense, or intervention on the part of the Government itself. For the last twenty-five or thirty years a Committee of the British Association has laboured at the gigantic task of building up a system of units, which involved as a mere preliminary the revision of the conceptions and units of dynamics in order that these might form a basis for the definition of units for the far more complex physical quantities concerned in electricity and magnetism, quantities many of which had previously been by no means clearly apprehended, and which then received for the first time precise statement and definition

Much of the work of the British Association Committee has been thankless, tedious, and, from its very nature. of a kind fitted to excite the cheap scorn of the self-styled "practical man," but it has made applied electricity possible, and has reacted in no slight degree on the progress of theory itself. The problem of the determination of the ohm-in other words, the process of realizing a standard of resistance according to the theoretical definition-has suggested problems to the theorist in the solution of which the theoretical investigator has been led to both direct and side-results of the very greatest value to the progress of science, and, in an unexpected manner, to the facilitation of practical applications. In no science have theory and practice been so closely connected during the last quarter of a century, and in none has the union been so markedly productive of good. By far the most interesting chapters of the history of electricity during the nineteenth century will be those that refer to its last three decades; may they chronicle a still closer alliance of the engineer and the experimenter, the electrical man of action and the mathematician ! Here union is strength and dominion over the forces of Nature : disunion is waste of energy and slow progress in all that relates to the material, and therefore also to the social, advancement of the human race by means of electrical invention.

The establishment of the nucleus of an electrical standardum; laboratory in London, and the appointment towards the end of last year of a Committee to decide upon and recommend for adoption electrical standards for use in trade, testify to the great importance which the electrical industries have attained in this country in spite of the mistakes which attended their inception, and the general discouragement and disfavour with which they were received by the various interests they threatened.

The preceedings and report of the Committee have just been published in a blue-book, which contains matter of great interest to all engaged in electrical work. The wrata which to opens up as regards the future operations of the standardzing laboratory may well diamay. Her Majesty's Government; although no doubt due provision will ultimately be made for all its work. But of this at another time; at present we wish to direct attention to the resolutions of the Committee, which will be found in another page.

In the first place the Commutee signify then adherence to the units of length, mass, and time as fundamental units, and adopt the C is S system. This was noty to be expected, for, after all, though some people may think that a better system could be devised if the work had to be done afresh, and they had a share in its still collectively the body of scientific opinion is distinctly conservative, and there is hitle danger that anylil-advised attempt to disarrange the accepted system of theoretical and practical units will success.

Their third resolution, that the standard of electrical resistance should be called the ohin and should have the value 1.000,000,000 in terms of the centimetre and second in the oidmary electromagnetic system, is of great importance It seems to settle once for all the question which has been debated over and over again, whether after a standard ohm has been realized, it will, like the standard yard or metre, be ever after the standard, or whether, if in case of variations in the physical properties of the substance, it shows an unexpectedly large divergence from the definition, a new standard ought to be constructed. Those who have assumed the former alternative have forgotten that the ohm is a derived unit. depending on the already fixed units of length, mass, and time, and that, therefore, its derivation ought to be as exact as the ever-widening resources of science can make it For practical purposes of trade the standard fixed

upon now and us copies are likely to remain undisturbed for a long time, and will probably only be corrected if there is serious alteration with time in their resistances. But the olim will still be defined as to C GS in the ordinary electromagnetic system of measurement, in which the magnetic permeability of air is assumed to be unity.

The fourth and fifth resolutions provide the definition of a practical realized ohm (1) by means of a column of mercury, (2) by comparison with the British Association until, which it is stated may be taken as 9866 of the ohm.

The wording of Resolution 4 strikes one as currous. The mercury column is to have a "constant cross-sectional area of 1 square millimetre" If "constant" has its ordinary sense of invariableness with time; the specification of 1 square millimetre renders it unnecessary. It has here apparently the usual sense of "uniform," that is, the section is the same at every part of the tube.

We are glad to see that the length adopted for the tround number adopted at the Paris Conference, and proposed, by the British Association Committee in 1889, by the British Association Committee in 1889 to be legalisted for a period of the ohm point to 106 3 as a convenient number very closely agreeing with the true value,

and its adoption now is probably only an anticipation of the decision which will be arrived at in a few years when the resolutions of that Conference are reconsidered.

In the adoption of a metallic working standard (announced in Resolution 5) the Committee only endorse an opinion long ago expressed by working electricians, that the mercury standards constructed in straight or spiral glass tubes are not practical instruments, they are difficult to handle, lable to breaked, and the only argument for their retention, the possible variability of metallic standards, has been shown to be almost baseless by the hosresults of the continued and careful observation of the various metallic resistance coils deposited at Cambridge-

Passing over the resolutions which provide for copies, and multiples and submultiples of the ohm, with the remark that the long-felt want of trustworthy standards of low resistance will now at last be supplied, we come to the definition of the unit of current Here again a theoretical definition corresponding to that of the ohm is given first . then for practical purposes it is stated "that an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of 0 001118 of a gramme per second, may be taken as a current of 1 ampere" This is the most reasonable course that could have been adopted. The specification is practically one of the procedure adopted by Lord Rayleigh in his experiments on the electro-chemical equivalent of silver, and as Lord Rayleigh's absolute result was to be made the practical standard, it was right to recommend the same mode of experimenting

Resolution 11, which defines the ampere in the case of an alternating current, was the subject of a good deal of discussion, and of some adverse comment by one of the witnesses examined on behalf of the electrical trades The resolution states "that an alternating current of I ampere shall mean a current such that the square root of the time-average of the square of its strength at each instant in amperes is unit; " It was pointed out by the witness referred to, and by at least one member of the Committee, that this was giving a very special meaning to the term, one, moreover, inconsistent with the obvious definition, that of the simple time average of the current This latter average would, in the case of most periodic machines, be simply zero, unless the currents in the alternate half-periods were commutated so as to agree, in sign with those in the other h lves. But in the case of such a machine as the Brush, used for lighting incander cent lamps, the definition given in the resolution would have to be used, whereas if the machine were used for electro-plating, the simple time average would have to be employed This would give for the same current passing through the machine, from instant to instant, two different average values The electric lighting application of periodic machines is, however, by far the most important, and the Committee did well, perhaps, to retain what is already the generally understood sense of the word ampere in connection with alternating currents. It ought to be, however, clearly understood that the main application of the definition will be to the measurements of eurrents in electric lighting, and that generally in other cases another definition will have to be employed

Another important discussion took place over the

definition of the standard unit of "pressure." In the first place, we should like to say here that we object entirely to the use of the term "pressure" in this connection. It has come as a sort of analogue of hydraulic pressure, and it has certainly led to very erroneous notions in the minds of the general public as to the functions of electric supply mains, and also as to electricity itself. It is a pity that so many of the present pioneers of electricity who are also leaders of physical science. should have countenanced by their example this misuse of a scientific term. We all know how strenuously some of these gentlemen have objected to the term "lension" as in "high-tension electricity", surely "high-pressure instruments" and "electricity supplied at high pressure" are as objectionable, if not even more misleading. The use of the term voltage, or some such word, in the present Report, would have avoided the endorsement which it seems to give to what we think is a most unfortunate name for a physical quantity which is not a pressure at all, and it is to be hoped that the British Association Committee (who, by the way, were represented on the Committee of the Board of Trade) may be able to prevent this phrase from being added to the many other, though generally less objectionable terms which infest the literature of electricity

A discussion arose as to whether the definition of the volt as the " pressure which, if steadily applied to a conductor whose resistance is one ohm, will produce a current of one ampere," was sufficiently definite. There might, it was argued, be an internal electromotive force in the conductor, and the " pressure" applied to the conductor might be regarded as that applied from the outside. or actually existent between its terminals, as shown by an electrometer. For example, the conductor might be the aimature of a dynamo, the difference of potential might be considerable and the resistance only a small fraction of an ohm In such a case it is, of course, well known that the electromotive force producing the current through any part of the armature resistance, according to Ohm's law, is the total internal electromotive force of that part, minus the difference of potential existing between its terminals (both being taken positive), and it is the difference thus obtained that is to be regarded as the applied "pressure" of the definition. In the same way in a voltameter, the electromotive force causing the current, according to Ohm's law, would be the existent or applied difference of potential, minus the internal back electromotive force developed by the chemical action There were other difficulties about the specification of the ends of the conductor and the canalization of the current, and it was therefore thought desirable to adhere to the simple form of definition given in the report. It must be admitted that the definition leaves room for legal disputes in practice, and we think that it would have been perhaps better to have introduced on these points some kind of note or specification referred to in the resolution, so as to be taken along with it in the event of any dispute about the meaning of the definition

A further question arose as to the provision of a practical standard of electromotive force in the form of a constant cell; and it was decided, partly in deference to the expressed wish of practical electricians, that the Clark cell should be adopted for this purpose. Its electro-

motive force, within certain limits of error to be determined by a sub-committee appointed for the purpose of preparing a specification for the construction and use of the cell, is stated to be I 433 volts at the temperature 62° F. By means of this cell and known resistances, it will be possible to calibrate instruments without the use of electrolysis, and this to many persons would be the readiest and most easily carried out method Of course, logically speaking, the standard of electromotive force is settled when those of resistance and current are fixed. and thus, if the order of definition is adhered to, the cell does not come in But its electromotive force having been determined by careful measurement, and found to be so constant as it is, and so consistently the same in different specimens when the mode of construction is carefully attended to, it is too valuable a standard of reference to be set aside

A very interesting discussion took place as to the mode of preparing these cells, and on the experience of different investigators as to their behaviour. Some of the divergences stated in the discussion were probably due to the different degrees of manipulative skill possessed by the various observers. A few carful experiments with different batches of cells carried out personally by the members of the committee interested in the matter would set the question at rest, and probably entirely confirm Lord Ravleigh's marvellowly consistent results

A side-point which came out in discussion is worthy of notice. We have not in this country any legal definition of temperature, whether Centigrade or Fahrenheit In the definition of the standard yard 62° Fahrenheit is specified, but there is nothing to tell how that temperature is to be determined. It is well known (though apparently not to some of the text-book writers on heat) that mercurial thermometers, mide with different kinds of glass, while agreeing at the freezing and boiling points, agree nowhere else, and all differ more or less from the air-thermometer. In very accurate work these discrepancies become very important, and thermometers must be calibrated by means of standards, if their indications are to be of any use for comparison. Some legal definition of temperature will, ere long, have to be given, and it seems rather a pity that the Committee did not practically settle this by saying what they meant by 62' Fahrenheit.

The definition of the volt for alternating currents, embodied in Resolution 15, 18, of course, a mere consequence of Resolution 11, and these two definitions taken together are specially applicable to the measurement of the power spent in lighting incandescent lamps

We have only to note that the Committee, in Resolutions 12 and 16, adopted instruments on the principle of the balance for the measurement of currents, and on the principle of Str. William Thomson's quadrant electrometer, used idiostatically, for the measurement of differences of potential—except for large differences, when an electrometer on the principle of the balance is to be employed. Thus the beautiful electrometers invented long ago by Sir William Thomson are likely to become at last, in a modified form, Board of Trade standards of exact measurement in industrial electricity. This is by no means the only striking example which could be cited of the thoroughly practical, because thoroughly theo

retical, character of the instruments invented by one who understands all sides of the difficult problem involved in the invention and construction of scientific apparatus

No resolutions were framed by the Commutee on the very important subject of the measurement of power and energy. This must, however, come to the front before very long, and will tax the resources of the standardizing laboratory and its officials, avaisted, as no doubt they will be, by Committees such as this which has just reported We congratulate the Committee in the results of its blooms, and trust that the requires 6 'rider in Council will be passed before long confirming its resolutions. The bioborted will then be able to get to work, the necessary standards which have been asked for so long will be made accessible to those engaged in the electrical indistricts, accessible to those engaged in the electrical indistricts, and the control of the

THE CONGRESS OF HYGIENE.

WL print to-day a report of the important discussion in Section II (Bacteriology) of the Congress of Hygiene, on "Immunity, Natural and Acquired" —

Dr. Rous, of the Institut Pateur, in an untroductory address, midcased the scope of the discussion. If to began by saying that, mirriting a pupil of M. Pateur to open the discussion on this object, the Originamic Committee faul reminded the Section object, the Originamic Committee faul reminded the Section between the Committee of the Section of the Section of the Section of the Section of Origin, and preventive morehizen, the two subjects with which Mr. Patteur's ances would for all time to subjects with which Mr. Patteur's ances would for all time to subjects with which Mr. Patteur's ances would for all time to subject with the only way of confirming immunity by morehizen to the original of the virts of the disease. To the old diagresson submed of producing immunity by monitation, and the original original original of the term vacanison. The designation "attenuated" virtue ought to be reserved for virtual weakened without brain attenuated the term vacanison. The designation "attenuated" virtue ought to be reserved for virtual virtual original attenuated and the production of the production of the virtual volt the originalists of the production of the virtual volt the originalists.

Methods of Ittenuation —Two methods of attenuation had been described by M. Pasteur—namely, the prolonged exposure of a culture to are at a sustable temperature, and the passage of the macroorganisms through the bodies of different species of animals. Other methods had also been employed—for example, the action of heat, the use of antiseptice, of compressed oxygen and light.

In all cases, whatever the method employed, it was found to be necessary that the attenuation should be effected slowly and agadually, rapid attenuation rendered a virus sliegether mactive which was the state of t

tori of the Chemical studiance produced by the macro organisms to the Chemical with a constant of the Chemical with the

into sensitive animals, the greater the degree of refractorineas shown by the animal, the more rapidly the microbes were con-sumed by the leucocytes In a non-resistant animal the microbes remained free; no such phenomenon as phagocytosis could be observed It seemed, therefore, that the phagocytes were charged with the defence of the human organism, and entered into con-flict with the parasites which infected the human frame. It might be said that there were diseases in which the filterobes were to be met with in the cells specially, and that these microbes nevertheless proved fatal to the animal. In tuberculosis and in leprosy the bacilli were to be found in the cells, and the results leprosy the bacilli were to be found in life cells, and the results were of the nons zerous kind, in spite of line intense phagogotous induced by the much of these tassess. The fact proved that the property of the control of the co had conquered It was not sufficient that the microbes should be eaten up, it was essential that they should also be digested by the phagocytes Even in those cases where the struggle was going against the human organism, these cells still were the ssors It had been frequently observed in tuberculosis and leprosy that the bacili had been killed in the interior of certain of these cells. The theory asserted that a struggle occurred between the microbes and the cells, but it did not imply that the bacili always won the day Phagocytosis only occurred in immune animals, in animals susceptible to the disease it was either not to be observed, or it was incomplete.

He then proceeded to discuss the questions whether immunity was the consequence of this power of the cells to digest the virulent microbes As had been said, the cells of a refractory animal took up the microbes, which, it would appear, under favourable circumstances remained mert in the interior of the cells. Numerous facts had been alleged to show that the microbes

Numrous facts had been aliged to show that the microbes to the time they were taken up by the phagocytes were the time they were taken up by the phagocytes were fall activity. Thus, to take only one example, it had been found that in forgs the bacility which had been taken up by the lecoptes remained alive within the protoplasm of the cell, this was apparent from their movements. In Jumph taken from the body of a pigeon, numerous bacilit were to be seen imprisoned in the lenceytes, and these bacilit could be wrateful growing. actually under the eye of the observer, within the interior of dead phagocytes, they could be seen to elongate, to push out the protoplasm, distort the form of the cell, and finally to make their escape. Another demonstration of the importance of the action of the phagocytes was afforded by the fact that even in immune animals the microhes were found to increase when kept out of the reach of the leucocytes; thus, if a rabbit were kept out of the reach of the leucocytes; thus, it a rabbit were inoculated in the anterior chamber of the eye, where there were no cells, the bacteriagrew freely, and their development was only checked when the leucocytes had after a time migrated in large numbers, and began to take the microbes into their interior. numbers, and began to take the microbes into their interior. It thus appeared that phagocytosus was a very general phenomenon, and one which was very efficacious in checking the advance of the organisms; when it failed, the individual succumbed to the virulence of the bacteria. The question remained, What was the mysterious force which attracted the cells towards the microbes? Why were the leucocytes, which in immune animals destroyed the microbes, incapable of seizing upon them in non immune animals?

In 1883, Metchnikoff propounded his theory of phagocytosis This theory rested on two assumptions . first, that the cells were attracted to the microbes in virtue of a special sensibility manifested towards all foreign bodies introduced into the tissues; the second was that this power of seizing upon the virulent microbes in immune animals originated in a habit formed during the earlier straggle with the attenuated virus with which the animal had been previously inconalised. The behaviour of the leucocytes might be more readily explained by assuming that leucocytes had been property, analogies to that possessed by the soosperms of the myromyceter—anamely, that possessed by the soosperms of the myromyceter—anamely, that the possessed by the soosperms of the myromyceter—anamely, that microbe exerted a very marked chemical action on the phagories. Without a virus was introduced into the body, it pre-iderated, and secreted a substance which attracted the lesco-ries. When a scarte the virus was the controlled into the body, it pre-iderated, and secreted a substance which attracted the lesco-ries. When scarter the virus was the controlled with the proposed of the controlled were the power of the controlled with the controlled proposed of the controlled was the controlled proposed of the controlled was the controlled proposed of the proposed proposed of the proposed pr formed during the earlier struggle with the attenuated virus with

indepable of taking up the microbes, which therefore proliferated without hindrance. Further, in certain diseases the virus produced a substance which was still more poisonous. In chicken duced a substance which was still more poisonous. In chicken cholors, for misance, the posons secreted by the microbes repelled the leucocytes from the point of inoculation; it thus came about that phagocytes were never found in this particular affection. This, however, was not the case with animals which had been rendered immune either by inoculation. of the attenuated virus, or by the injection of a suitable dose of bacterial products If the animal were given a strong virus, phagocytes were attracted to the point of inoculation, and these possessed the power of taking up the microbes before they had time to elaborate effective doses of their toxic material. It was, therefore, at the commencement of the disease that the critical struggle took place. If the leucocytes could not the critical struggle took place. If the leucocytes could not as compilate his at the beginning of the malady, hear action as a fairer period would be useless, since the microbes would have profused enough posens to peralyze their activity. Every point of isocialision facilitated infection. The theory of immunity proponed by M. Metchikoff did not exclude the possibility of there being other means of protecting the organism, and it may prove the highest protecting the organism. The steme of the replace of the protecting the organism of the protecting the organism of the protecting the organism. It seemed to explain all the facts, and was, moreover, eminently suggestive. It was in this way that the knowledge of microbic polions and chemical inociation when the protection of the Far from being shaken by the theories which were opposed to it, this theory of Metchnikoff's had gained by the opposition which it has met, and that was a guarantee of its soundness

Dr. Buchner, of Munich, after giving a general account of the various theories of immunity, criticized freely Metchnikoff's views The main objections he brought forward were as follows .--

(1) Many observers failed to notice any destruction of bacilli

(a) In sup observers tasted to notice any oestimetion of oscillation by phagocytes, when naturally immune animals, such as white rats or pigeons, were inoculated with anthrax (a) In dis-asses ending fatally, such as tuberculosis, mice-septicemis, &c., the micro organisms were frequently found in the interior of plagocytes.

(3) The experiments of Petruchky, Baumgarten, Pekelharing, and others seemed to show that the bacilli of anthrax perished in the living fluids of immune animals even when the bacillt

were protected against the attacks of white corpuscles
Metchnikoff, however, denied this, and proved that the
living fluids of immune white rats form a most excellent cultivatliving fluids of immune white rais form a most excellent cultivating medium for the bacility of anithrax. These observations of Metchnikoff, according to Buchner, might be explained by the fact that Metchnikoff in his experiments introduced more bacilli than could be destroyed by the living fluids of white rais, occini inan count of netturyer of the invite interest of the extract of the state of the variety of micro-organisms. Speaking of the experiments made by his pupils benefit and Roeder, he stated that, when a certain kind of micro organisms were placed into a given quantity of serum, the nincro organisms might either be destroyed in toto, or reproduce themselves in large numbers according to the serum When, instead of placing the micro organisms directly serum when, instead of pincing the inter-organisms were wrapped up in sterilised coston wood, it was found that the bacilit, so protected against the temporary harmful influence of serum, began to grow luxurantly at the end of twenty-four hours. The bacterioidal power of serum disappeared, therefore, shortly after

Massart, Bordet, and Gabritchewsky had previously proved that the emigration of leucocytes to the spot where the virus was that the enligration of leucocytes to the spot where the vrust was introduced was due to the attracting influence (positive chemo-taxis) of the chemical posions secreted by micro organizas, but the thread the second organization of the control of the thread organization of the control of the control of the attracting influence on leucocytes was due to the products of present in bacterial cells themselve. Whereas the products of the metabolism of micro-organization had little or no attracting in-tenence on the lengocytes, the products in themselves suitarted the

fluence on the leucocytes, the proteins themselves attracted the cells most powerfully.

As long as the bacterial cells were active and capable of repro-ducing themselves actively, the proteins were contained in the cells, and these poisons only left the cells when the latter

became diseased or old Hence these proteins were chiefly found in old columns, the filtered and sternised extracts of which a lwfy pleased as time, strateling of leaves the color of the c the living fluids of the body exert a harmful influence on micro-organisms, and then, when in consequence of this the excretion

organisms, and then, when in consequence of this the exerction of proteins take place, the amenbod cells emgrate to the spots of the protein takes place that the protein takes the protein take the micro-organisms themselves, for, unless the latter were completely detroyed, they son began to grow friely in 'erum'. This germidial substance was easily destroyed by heat Serum which had been maintained at 55°C during half an hour, or at 52°C during six hours, lost its bactericadal power completely. A moderate degree of warmfit (37°C) intensified the germicalal

action of the blood or serum.

Turning now to the question as to whether this bactericidal ection of the blood had any share in the production of immunity, he gave the following facts as proving that there was some con nection between the immunity of a given animal against a given infectious disease, and the hactericidal action of its blood on the (a) The blood and scrum of animals, such as mice and guines

pigs, which readily succumbed to anthrax had no bactericidal power on anthrax-bacilli

(b) The serum of animals which took anthrax readily never possessed such a strong bactericidal action as the serum of white rats, which were immine against anthiax

(c) The blood and scrum of animals rendered artificially immune possessed stronger bactericidal powers than the blood

(d) The blood and serum of animals rendered artificially immune against a given micro organism lessened the virulence of the specific micro organism causing the disease

Whenever blood and serum possessed no hactericidal action on micro organisms, this absence of bactericidal action might be due to the fact that, owing to the necessary manipulations, this bactericidal substance had been altered or even

As further proving that the immunity of animals depended on some substance present in the serum, he mentioned the facts described by Behring, Kitasato, Ogata, and Emmerich, in which the injection of blood or serum of an animal immune against a given bacillu-, cured another animal afflicted with the same disease. This curative power he attributed to the presence in disease. In curative power is attributed to the present in the blood of immune animals of a protective substance, probabily proteid in its nature, to which he gave the name of "alexine" (from alexies, to protect). These alexines were not ordinary oxidation products of the tissues, as they were quite specific in ostuation products of the tissues, as they were quite specime in their action. They were not simply enzymes, as they had no hydrolytic properties, but they were most probably protect sub-stances. These alexines were probably formed in the cells; but, when formed, their action was quite independent from that of cells, and they were probably always present in immune animals

Mr. E. H. Hankin, of Cambridge, after giving a réumé of the work done by various observers, said that theoretical considerations led him to suspect that a particular ferment-like protects, known as cell globulin B, was a substance possessing bacterical power I let tested that action on anthrax bacilli, and found that I had the power of destroying these microbes. The control of t

only in animals that were naturally immune against anthrax, but also in those that were susceptible to this disease stances he had given the name of defensive proteids. To these sublished papers on this subject he had noted various similarities in the bactericidal action of these substances, and that possessed by blood serum, and these resemblances were such as to leave little room for doubt that the bactericidal action of blood-serum was due to the presence of these defensive proteids.

The serum of white rats contained a proteid body postessing a well-marked alkaline reaction, and a power of destroying an-intract bacilli. Further, when injected into mice along with fully virulent anthrax spores, it would prevent the development of the

On the other hand, defensive proteids of animals sus ceptible to anthrax did not exert such protective power, and ceptible to althrax did not exert such protective power, and consequently these experiments indicated a difference in the mode of action of defensive proteids of immune and non-immune animals respectively Further, the amount of defensive proteid present in a rat could be diminished by the causes which were known to be capable of lowering the animal's power of resisting anthrax. For instance, Feser stated that rats become succeptible to anthrax when fed on a vegetarian diet. Mr. Hankin obtained similar results with wild rats. The ordinary white rat he found to be generally refractory to antheax on any rat ne tound to be generally retractory to animax on any diet, and the defensive protest could always be obtained from its spleen and blood serum. This was not the case with wild In one experiment eight wild rais were used, of these, four were fed on bread and meat, the others on plain bread, for about six weeks Then one rat of each lot was inoculated with an were ted to meet a service of the death of the way inoculated with an thray, of these, the one that had been subjected to a bread diet succumbed. The remaining rais were killed, and it was found that while the spleens of the flesh fed rats contained abundance of the defenser protest, only traces of this substance could be obtained from the spleens of the rats that had been fed on bread obtained from the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the rats that had been fed on bread the spleens of the s

aione A similar result was on-timed in other experiments. Very young rats were known to be susceptible to anthras, and so far as could be judged from the litmus text (after dialysis and addition of NaCl), their serum appeared to contain less of the defensive protect than did that of the adult sat. Further, the little from the little provided by a young rat could be preserved from the little from the little provided by the provided provided to the provided provided the provided from the little from the little provided the provided from the little from t anthrax by an injection of its parent's blood serum

These facts appeared to prove that the defensive proteid of the rat deserved its name, in that it preserves the animal from the attack of the anthrax microbe, in other words, that this substance was at any rate a part cause of the rat's immunity against anthrax

Defensive proteids appeared to be ferment like, albuminous bolies, and it was extremely unlikely that we should for a considerable time be able to classify them by any other than physiological tests. From this point of view it was possible to divide them into two classes, first, those occurring naturally in divide them into two ciasses, ints, into eccurring naturating in normal animals, and secondly, those occurring in animals that have artificially been made immune. For these two classes Mr. Hankin proposed the names of its arm and phylamen, A. "sound" was a defensive potent that occurred naturally in a normal animal. They had been found in all animals, jet examined, and appear to act on numerous kinds of intribusion on their products. A. "Phylistana" was a defensive protected which was only found in an animal that had been artificially made immune against a disease, and which (so far as is yet known) only acted on one kind of microbe or on its products

hach of these classes of defensive proteids could obviously be further subdivided into those that acted on the microbe itself, and those that acted on the poisons it generated. These suband those that acted on the pounds it generated. These sub-classes he probate to denote by a deling the prefices myos and classes he probated to denote by a deling the prefices myos and proteed occurring in the normal annual, which had the power of acting on various speecs of meroide. Two costans were idensity protests, also occurring in the normal annual, which is the probate of the probate of the probate of the meroide strength of the probate of the probate of the meroides. Myon phisars and too physicars maintaily would denote the two sub-classes of the physians graining two probates of the properties of the physians graining the sub-denote the two sub-classes of the physians grained to the desired control might be represented by the following

scheme :-

Prof. Emmerich, of Munich, read a paper on "The Artificial Production of Immunity against Croupous Paeumonia and the

Cure of this Disease." He stated that his previous experiments on swine fever had proved that in immune animals the bacilli of on swine fever had proved that in itimune authorized swine fever were destroyed, not by the cells of theanimal, but by a bacterickial substance present in the blood. It had been clearly proved by his experiments that the bacilli of swine fever were destroyed almost immediately after their introduction were destroyed almost immediately after their introduction under an immune animal's skin. Applying these researches to the disease produced in rabbits by the inoculation of the Diplocaccus premiums of Franchel, he showed that non-immune rabbits died within twenty four to forty-eight hours after the introduction of the virus. But if such animals had been preintroduction of the virus. But if such animals had been pre-viously treated with the blood or serum of animals rendered artificially immune against the diplococcus of Fraenkel, such animals did not die, but recovered after the introduction of extremely virulent diplococcu. Moreover, when the Diplococcus fricumonic was inoculated into an animal, it was possible to cure it by injecting shortly afterwards some of the serum of an animal rendered artificially immune. In the blood of animals amusin removed artificially immune. In the blood of animals rendered artificially immune against pneumonia we possessed an excellent cure for the disease. Not only would it be possible to cure men affilied with pneumonia by these injections, but we could, by preventive inoculations applied in time, put a stop to the spread of an epidemic in a school or a prison for instance His experiments, together with Dr. Doenissen's, had a great practical as well as a theoretical value

Dr Ehrlich, of Berlin, stated that he had lately made a number of experiments with ricin which threw great light on the question of immunity According to Kobert and Stillmark, ricin was an extremely poisonous body, for it acted fatally when such small doses as 0 03 mg were injected into an animal's veins. When absorbed through the alimentary canal, a dose 100 times larger could be easily tolerated. Nevertheless, even then, it was so toxic that, according to Kobert's reckoning, a dose of 0 18 gr would prove fatal to a full-grown man It had a harmful influence on the blood, producing coagulation of the red blood-corpuscles, and thromboses, more especially of the vessels of the alimentary canal

In his opinion the toxicity of ricin greatly depended on the in his opinion the toxicity of rich greatly depended on the species of animals used for experiments, the animals most susceptible to its action being quineapings. Thus, a guineaping weighing 385 grammes died eleven days after the inoculation of 7 cc of a 1 in 150,000 solution of rich, the fort most reason and the specific production is showing characteristic homorrhages in the allexamination showing characteristic influential transfer in the all-mentary tract. One gramme of this substance might therefore prove fatal to 1,500,000 guinea pigs. While mice, on the other hand, did not die after much larger doses, and this immunity of name, due not due after much larger doses, and this immunity of mice against this potton might be increased by sullicutaneous injections of ricin. The same result might be obtained, how-ever, far more essaly and without any chances of failure, by feeding mice with ricin. It was best to begin with mail, harmless doses, gradually increasing the amount until the or-ganism was accustomed to the poisonous substance. In ten days a mone might then be inoculated with a deadly or even days a moise might then be inocurated with a deathy of even larger dose without suffering any evil effects. Thus, whilst doses of 1/200000 gramme was absolutely fatal in normal animals, mice fed daily and in increasing quantities with ricin suffered no harm after the injection of 1/1000 gr or 1/500 gr.,

or, occasionally, of 1/250 gr

Whilst a 0 5 or 1 per cent solution of ricin applied to the eye of a normal animal produced severe inflammation and eye of a normal animal produced severe innammation ame panophilalmint; the application of a to per cent solution of ruen produced no effect on the eye of an animal previously fed with rein! In other words, this was distinct proof of the existence of a local a well as of a general innumity against the poison. Strangely enough it was almost impossible to render the subcutaneous tissue immune against ricin, and even in exceedingly immune animals the subcutaneous injection of ricin pro-duced distinct necrosis of the subcutaneous issue

It was a remarkable fact that this immunity appeared quite auddenly on the sixth day, and then increased slowly, so that on the twenty-figst day the animal could stand a dose which was 400 times higher than that fatal to a normal animal.

This immunity against item appeared to be permanent, for it was still present in immune mice which had not taken ricin for

a period of six months previously

He had been able to extract from the blood of animals rendered immune against ricin a body which had the power of counteracting the toxic action of ricin, so that a powerful solu-tion of ricin was rendered harmless by admixture with the blood

of immune mice. It was also possible to render animals immune against ricin by injecting the blood of immune animals. He had obtained similar results with abrin, which would be shortly published.

Dr. Kitasato, of Tokio, shortly summarized the results which he and Dr. Behring had obtained with the virus of tetanus.

According to these observers, the blood of a normal rabbit has no influence on the toxines secreted by the hacillus of tetanus. But when a rabbit had been rendered artificially immune against But when a rabbit had been rendered artificially immune against that disease, is blood had the power of destroying the toxine secreted by the specific bacillus. Nay, more, the blood of rab-bits made artificially immune against tenans with trichloride of todine, rendered mice not only refractory to telanus but also curred the disease when already in progress. The blood, how-ever, did not appear to act on the telanus bacillus itself, but on

ever, did not appear to act on the tetanus bacillus itself, but on the tormes secreted by the bacillus. The transposition of the Dr. Adams, of Cambridge, though that it was unpossible to the control of the control of the control of the control of phagocytosis was extraency marketins diseases the process it was quite possible to accept both views of the question. The controversy had taken place chefly as to the phenomen observed in the rat, in that animal phagocytosis was only to be observed with difficulty, and the serims of rat's blood unboulstelly pos-

bessed bacteria-killing properties to a high degree.

Dr. Klein, of London, stated that frogs and rats were mesusceptible to authrax, but that these animals could be made ceptible to authrax, but that these animals could be 'made susceptible to the disease by a variety of means, indicating that their normal power of resistance was due to certain chemical conditions of the blood. If the bacultus of anthrax was introduced into the lymph-sec of a chloroformed frog, this animal always duel of authrax. Rats incoulated with anthrax and kept under the influence of an anischetic also died of anthrax. If le had been unable to find any evidence to show that in these cases the leucocytes had lost their power of swallowing up bacteria, and therefore the susceptibility of chloroformed animals to anihrax could only be explained by some chemical changes taking place in the serum of the chloroformed rat or frog

Dr Metchnikoff, of Paris, who was greeted with loud and pro-longed cheering, said that, of all the objections which have been raised against the theory of phagocytes, doubless by far the most important was that formulated by Behring and Nissea. namely, the fact that the serum of guines-pigs vaccinated against the vibrio of Metchnikoff had bactericidal powers on the same vibrio. Whilst the serum of normal guinea pigs allowed the free development of a large number of these microbes, the serum of vaccinated animals killed the micro organisms at the end of a few hours. MM. Behring and Nissen were convinced that this fact formed a complete explanation of the acquired immunity of guinca-pigs against the Vierio Metchnikeli, and that it might serve as a model for a theory of immunity. His own researches, however, proved the contrary. If one studied the phenomena as they occurred in the living animal, one noticed at once that the hacili inoculated into immune guines pigs remained alive for a very long time. Some vibrios were taken into the interior of very long time Some vibrios were taken into the interior of leucocytes at the point of inoculation, whilst others developed perfectly in the liquid exudation. To show this, one had only to take a drop of the latter, and place it in the warm chamber, the leucocytes perished when taken out of the organism, and allowed the bacilli contained in their interior to develop freely.
The whrons thus multiplied and filled the leucocytes, which swelled and eventually burst, allowing the microbes to pass freely into the liquid part of the exudation

Here the development continued, and one obtained very abundant cultures from the liquid exudation of the immune guinea pig. If one ex-tracted a small quantity of such a culture, and introduced it into the dead serum of an immune guinea-pig, this serum not only did not kill the bacili, but also gave a more abundant development than the serum of a non-immune animal could do. The ment han the serum of a non-immune animal could do. The study of the phenomena in lying animals used artificially im-mune against the vibro of Metchnikoff, instead of overthrowing the theory of plagocytions, furnished on the contrary an evident proof in its favour. The theories of the attenuation of virus in the bodies of immune animals, and of the neutrilization of the totainer, could not be applied to his case, as the vibrour re-cording to the contrary of the proof of the country of the assectivity or the exercise of the bendling as the non-ingrussed as sensure to the toxine of the bacillus as the non-immune anımal.

This example showed yet once more that one must not be content with studying the phenomena of immunity outside the

This criticism also applied to M, Buchner's experiorganism. ments, which he had communicated to this meeting, he insisted on the fact that, in order to assure one's self thoroughly of the on the fact that, in order to assure one's self thoroughly of the betternical property of the sering, it was necessary to take a sering the ser ner. instead of furnishing an objection to the phagocyte theory, rather supported it

Referring to the curative properties of the serum of white rats against anthrax, he had come to the conclusion that, whereas the living serum of white rats had no bactericidal action on anthrax, the dead serum of the same animals had marked bactericidal powers on the same micro-organism. When a mouse was inoculated with a mixture of the dead serum of a rat and anthrax bacilli, it nearly always died, although the disease lasted somewhat longer than usual On examination of the point of inoculation it was found that the bacilli of anthrax did not grow quite so readily, and that an enormous number of leucocytes emigrated to the point of inoculation and took the bacilli into their interior and digested them In tetanus, again, the leucocytes are up con-siderable quantities of tetanus spores and bacilli. Summing up his researches, he stated that whenever an animal recovered from an infectious disease this recovery was accompanied by a process of phagocytosis, whenever an animal died of an in-fectious disease the process of phagocytosis was absent or insufficient. The theory of phagocytes was strictly based on the

SECTION F

GEOGRATIIA. OPENING ADDRESS BY E. G. RAVENSTEIN, F.R.G.S., F.S.S., PRESIDENT OF THE SECTION

The Field of Geography

It behoves every man from time to time to survey the field of his labours, and to render an account unto himself of the work he has accomplished, and of the tasks which still await him, in order that he may perceive whether the means employed hitherto are commensurate with the magnitude of his undertaking, and likely to lead up to the desired results Such a survey of the "Field of Geography" I propose to make the subject of my address to-day

Whatever changes may have taken place respecting the aims of the geographer, it is very generally acknowledged that the rortrature of the carth's surface in the shape of a map lies within his proper and immediate domain. And there can be no doubt that a map possesses unique facilities for recording the fundamental facts of geographical knowledge, and that with a

Pressure on our space compels us to omit some parts of this a idress.

clearness and perspicuity not attainable by any other method. You will not, therefore, think it strange if I deal at considerable length with he development of cartography, more especially so my own labours have in a large measure been devoted to that department of geographical work. An inspection of the interesting collection of maps of all ages which I am able to place before you will serve to distinctive what I am about to say on this

subject...

It is all great reformers, stood upon the shoulders of the one who had preceded him, for before a map the he to could be the proceded him, for before a map the he could be produced much preliminary work had been accomplished. Parmenders of Elea (460 m c) had demonstrated that our earth was a globe, and Existinhenes (276-196 m c) had approximately determined us sure. Hipparchas (190-196) he greatest actionsomer of the standard produced to the contract of the standard produced to our earth the acultary lines standard by the standard transferred to our earth the acultary lines standard by the standard lines standard the standard produced to the standard lines standard the standard produced to the standard lines standard li

The gnome or van dial, an instrument known to the Chinese Goo years beine Christ, had long been used for the determination of latitudes, and the results were relatively correct, although uniformly subject to an error of 16 minutes, which was due to the observers taking the altitude of the upper limb of the sun, when measuring the shadow cast by their dial, instead of that of

the unis centre
It was known, likewise, that differences of longitude could be determited by the sumulaneous observation of eclipses of the san or moon, or of occulations of stars, and Ilpaperdus actually computations. Prolemy himself suggested the use of loars distances. But so imperfect were the astrolabes and other interferences are the sumulations of the sumulation of the sumulation

No copy of Fiolemy's original set of maps has reached us, for maps drawn by Agathodzmon in the fifth entury are, under the most favourable circumstances, merely reductions of Ptolemy's which apart from a few explanatory chapters, consains almost which, apart from a few explanatory chapters, consains almost modified to adopt the latter view—firstly, because of an almost inclined to adopt the latter view—firstly, because of rate exclastral survey was available, and accordity on account of the cylindract projection on which these maps are drawn, although from Ptolemy's own statements we are justified in the collections that the made due of a concoll projection on in the con-

The three longuades are the follows g -

| Result of ancient | Adopted by Actual difference | Actual differ

An examination of Polemy's maps above very clearly that they were almost wholly complete from internate, the greater number of which their subtle borrowed from his prediceases and an examination of the predicease are compiler cannot be rated very high, and that he failed to utilize much information of a geographical nature which was available in his day. His great merit consisted in having taught earlier graphers to constitute their maps according to a scentific method. This lesson, however, they were slow to lean, and centuries both the control of the co

During the "Dark Age," which followed the dimemberment of the found Empire there was no lack of range, but hely were utterly worthless from a scennife point of reew. The achievements of the accients were ignored, and the principal sum of the map-makes of the period appears to have been to the Holy Scriptures. Hence those numerous "wheel maps," upon which Jerusalem is unade to represent the hul, whilst the sectors half of the dask is assigned to Europe and Africa, and

As it is not my intention to introduce you to the archieological curiosities of an uncritical age, but to give you some idea of the progress of cartography, I at once pass on to the Arabis

Araba were great is traveller, greater nill a sutronomen, fully possessed of the knowledge of Ptolemy, throwest of the error of the gromon, the ymproved the nativanear when the promon the household of the promon, the household of the promon, the household of the promon of the promon of places. Zarkala, the Director of the Observatory of Toleda, even attempted to determine the difference to great a number of places. Zarkala, the Director of the Observatory of Toleda, even attempted to determine the difference to great a distance of the Control of § from the truth, it nevertheless proved a great advance upon Ptolemy, whose map exhibits an error anomating to 18. Had there existed as sentitific extregrapher among the Araba, he would have been able, distance made by exactful of never hie Araba Ilasan, to effect most material corrections in the map of the known world. If Edma's mag (154) is better than that of others of his Araba contemporaries, this is slipitly due to his residence at Federms, where he was table to sawd his need of the knowledge.

Quite a new epoch in the history of cartography begins with the introduction of the magnetic seeds into Juripe. Hitherto the mirroduction of the magnetic seeds in the Juripe. Hitherto heaves, themeforth an instrument was placed in his hands which made him independent of the uate of the sky. The property of the magnet or "loadintone" to point to the morth appeared to the morth of the property of the magnet or "loadintone" to point to the morth Alexander Neckam [1183] it was already possed upon a proct. It was, however, only after Theory Giospi of Ansail (1921) had the wands, that it became of such ammediate importance to the marner. It is only natural that the Italians, who were the foremost scamen of that age, should have been the first to avail date, as early probably as the twelfile centure, they made use of it for their maximume warveys, and in course of time they proceed a series of charts agon which the coasts frequented by which the coast frequented by the contract of the state of the

will prove this to you. The delineation of Italy, on the so called Catalan map, is surprisingly correct; whilst Gastaldo, whose map of Italy is nearly two hundred years younger, has not yet been able to emancipate himself from the overpowering authority of Ptolemy. And in this he did not sin alone, for Italian and other cartographers of a much later time still clung pertinaciously to the same error

ciously to the same error

There were others, however, who recognized the value of
these charts, and embodied them in maps of the entire world.

Among such were Marino Sanuto (1320) and Fra Mauro (1453),
both of whom made their maps the repository of much information gathered from the Arabs or from their own countrymen who had seen foreign parts. Fra Mauro, more especially has trans-mitted to us a picture of Abyssinia marvellously correct in its

matted to us a picurie of ADysums matteriously correct in its details, though grously engagerated in us timensions when the cartographers and pilots of Dortugal and Spain returned to the reade projection of Dicearach, Eratosthenes, and Marinus, which enabled them to lay down places according to latitude and longitude upon their "Plane charts."

Germany, debarred from taking a share in the great maritime discoveries of the age, indirectly contributed to their success by improvements in mathematical geography and the introduction of superior instruments. The manipators of the early middle

Lalande formed the basis of all astronomical calculations during a century, that more exact results were obtained. The suggestion to determine long tude by means of lunar distances or occul of stars bore no fruit at that time, as the knowledge of the com-plicated motion of the moon was still very imperiect. Still less picacea motion of the moon was still very imperfect. Still less was known about the movements of the satellates of Jupiter, which Galileo had first capied in 1610 when looking at that planet through his telescope. They became available only after tables of their revolutions and eclipses had been published by Cassini in 1668

Another suggestion for the determination of longitude was Another suggestion for the determination of longitude was made by German Fristus in 1530—namely, that a clock or time-keeper should be employed for the purpose. One of Huygens's pendulum clocks was actually carried by Holmes to the Guif of Guinea, but the results obtained were far from encouraging.

The difficulties which still attended the determination of origitude in the sixteenth century are conspicuously illustrated by the abortive attempts of a Congress of Spanish and Portuguese navigators who met at Badajoz and Yelves in 1524 for the purpose of laying down the boundary line, which Pope Alexander VI of laying down the boundary line, which Pope Alexander VI had drawn at a distance of 370 byanish leigues to the west of Cape Verde Islands, to separate the dominions of Spain from those of Portugal. Not being able to agree either as to the length of a degree, nor even as to that of a league, they separated without settling the question placed before their

ages still made use of an astrolabe when they deared to determine a latitude, but this instrument, which in the hands of an expert observer furnished excellent results on land, was of little use to a pilot stationed on the unsteady deck of a vessel use to a pitol statuored on the unateasy deck of a vessel Regiononians' conveyeently conferred as immerse service upon an instrument alterady known to the cordinary surveyors. It was this cross-staff which Martin Beham introduced into the Pottsguese navy, and which queekly made its way among the margation of all countries. Most observations a rea were course of ages, until it was superseded by Habiley's sextant. In the hands of the more shallin unarigations of the seventeenth entirely, such as Baffin, James, and Taman, the results obtained with the cross staff were correct within two or three manues. Far greater difficulties were experienced in the observations of with the cities and the west of the control of the parts 1474 to 1506, which Columbus carried with him on his voyages, nor those of Peter Apinans, for 1321-70, were sufficiently ac-curate to admit of satisfactory results, even though the setum tade were by no means are, and it was only which Replet had published his "Radolphire Tables" (1626), which according to NO. 1140, NO. 1441. Regiomontanus consequently conferred an immense service upon

So uncertain were the results of observations for longitude made during the sixteenth and seventeenth centuries, that it was thought advisable to trust to the results of dead-reckoning rather than to those of celestial observations. But the method of deadthought advanable to trust to the results of dead-resconing railer than to those of celestial observations. But the method of dead-reckoning is available only when we have a knowledge of the save of the earth, and this knowledge was still very imperfect, notwithstanding the resewed measurement of an arc of the meridate by Seellus, the Dutch mathematicism (1615). This measurement, however, is remarkable on account of its having for the first time applied the exact method of trangulation to a survey.

The problem of measuring the ship's way had been attempted by the Romana, who dragged paddle-wheels behind their ships, the revolutions of which enabled them to estimate the distance which the ship had travelled. But time, the strength of the wind, and the pilot's knowledge of the qualities of his ship, still constituted the principal elements for calculations of this kind, constituted the principal elements for calculations of flux kind, for the "catena a poppa" which Magellan attached to the for the "catena a poppa" which Magellan attached to the constant of 1577.

The eminent position which Italian cattographers occupied daming the fourteenth and fifteenth entimers had to be sur-rendered by them, in the beginning of the susteenth, to their rendered by them, in the beginning of the susteenth, to their properties of the control of the susteenth, to their properties of the control of the susteenth, to their properties of the control of the susteenth and the susteenth

"The German eartographers of that age are to be commended, not because they copied Ptolemy's mapped on its this they had been preceded by others—but because they adopted his scientific method in producing maps of their own. Their efforms began at home, as all reforms should. They were amply supposed as the commendation of the producing the producing

at a much later date.

Perhaps the earliest general map of Germany, and critality one of the most interesting, was that which the fimous Cardinal Nicolas of Cises or Clies completed in 1464, the only existing was "decovered" by Baron Nordenkulod Sercator's map of Germany, published more than a century after that of the learned certified (1614), was naturally far more complete in all recentually the control of the century of the control of the century of the century state of the century sta

The crull of having dose most towards the promotion of entography in the course of the eighteenth century belongs to France. It was France which first equipped expeditions to determine the use of the earth. France which produced the first topographical map based upon scientific survey—a work began by Cear Françoi Cammin 11744, and completed by his son five years after his father's death, at was France, again, which would have very sentle, the first crucial carriage plane whom the world had ever sentle, the first crucial carriage plane whom the

Delide (1675-1736), a pupil of Casumis, had already been able to rectify the maps of the period by uttining the many astronomical observations which French Iravellers had Iraveller home from all parts of the world. This work of reform was carried further by 17 Arnollie (1675-1752), shot werent sawty the home to us the pretty of our knowledge, who boldly refused to believe in the eavience of an Antarctic continent covering all the southern benutyhere, and always brought stoond jurig ment to bear upon the materials which the over increasing ment to bear upon the materials which the over increasing eight the southern and the south

In that country the discovered of Cook and of other famous mergators, and the spread of Blush power in floids, gave the first impairs to a more diligent cultivation of the art of representant in the surface of the earth on many. There, to a general extent into exhetence a wast number of charts, amongst which are many bundred of these published by Dalympide and looped Debarred by the property of the property of

mandate in the property of the present century Germany has once more become the head quarters of sentific caterography, and this is due as much to the inspiriting teachings of a fixiter and a litembodit as to the general culture and selection training, common the property of the proper

And now, at the close of this nineleenth century, we may fairly boast that the combined science and skill of surveyors and cartographers, aided as they are by the great advance of the

graphic arts, are fully equal to the production of a map which abili he a faithful image of the earli's surface. Let us linegare for one moment that an ideal map of the kind were before us, a map exhibiting not mently the features of the land and the depth of the sas, but also the extent of forests and of pasture lands, the distribution of human habitomos, and all those features the distribution of human habitomos, and all those features the physical and statistical altises. Let as then analyze the rais mass of facts that pleaced before us, and use shall hud that they form quite naturally two well-defined divisions—namely, those of physical and political geograph—whils the third department of our science, mathematical geograph—whils the third department of our science, mathematical geograph—with the third department of our science, mathematical geograph—will introduce of which is

"I shall abstain from groung a laboured definition of whal I consider geography should enhance, for definition of this kind help practical workers but luttle, and will never deter anyone who feels duponed and capable from straying into feels which an absets of lege that clearly demonstrated to lie outside his an absets of lege that clearly demonstrated to lie outside his and chorography, the description of particular places or of entire countries, should always be looked upon as integral portions of geographical research. It is they which farmish many of the blooks needed to rear our geographical editine, and which combined the contribution of pactical processing and the contribution of pactical geographical editine, and which combined the countries of pactical eccentricity.

That our maps, however elaborate, should be supplemented by descriptions will not even be gain-and hythose who are most reluctant to grant as our independent extender among the sences which deal with the cartin and mm who mibalis at villow ourselves to be reduced to the post on of collection, of facts. We claim the right to discovery ourselves the facts we have collected, to analyze them, to generalize from them, and to trace the correlations between came, and effect. It is thus that geography hecomes comparative, and white comparative the citing sufficient features of our earth, comparative the citing suffice features of our earth, comparative of the confidence of the

smooth was of multiply califyrated by level letter. Man is indeed in a large neasure "the creature of his environment," for who can doubt for a moment that geographical conditions have largely influenced the destinate of rutions, laved directed the builders of our towns, determined the paths of nungrations and the march of armies, and have impressed their value pere upon the character of those who have been subjected to them for a sufficiently extended period?

It must not, however, he assumed for one moment that the dependence of man upon Nature is abolute. The natural recourses of a country require for their full development a people of energy and capasity, and instances in which they have been allowed to the dormant, or have been wasted, are

Perhaps one of the most instructive illustrations of the complete human agencies which tend to modify the claitive importance of geographical conditions is presented to us by the Mediterranean of the world's commerce, whilst the horses of Western Europe were only occasionally vasited by venturesome navigations or onspering Roman hosts, does not lie so very for behind us, or onspering Roman hosts, does not lie so very for behind us, Europe, of which it was a mere dependency. The prosperity of the Mediterranean countries survived far into the middle ages, and faily at one time enjoyed the envalde position of the Mediterranean countries survived far into the middle ages, and faily at one time enjoyed the envalde position of the Mediterranean countries and to Germany, and through the gates of Gibnaltar to the exterior occan. But a change was brought shost, partly through the closing of the old Criential through the discovery of a new world and of a mantime highway to India. When Columbas, hisself an Islain, returned from the West Indices in 1493, and Vasco da Gama brought the fair face. And shifts the speec of the Indies and the gold of Gunes powerd wealth into the lap of Portugal, and Spain grew quient on the ulter mass of Mexico and Pens, Vesico was

valuly beseething the Sultan to reopen the old trade route through the Red Sea. The dominion of the sea had passed by the Red Sea. The dominion of the sea had passed by the Red Sea. The dominion of the Red Sea Red and political institutions found a home in a new world

and pointest institutions town a nome in a new world.

And now, when the old highway through the Red Sea has been reopened, when the wealth flowing through the Canal of Secz is beginning to revivily the commerce of Italy, England may comfort herself with the thought that in her own colonies and in the States which have sprung up across the Atlantic she may find ample compensation for any possible loss that may accrue to her through geographical advantages being once more allowed to have full play

I am afraid I have unduly tried your patience. I lelieve you will agree with me that no single individual can be expected to master all those departments which are embraced within the wide field of geography Even the mater mind of a Humboldt fell short of this, and facts have accumulated since his time at an appalling rate. All that can be expected of our modern geographer is that he should command a comprehensive general view of his field, and that he should devote his energies and capacities to the thorough cultivation of one or more departments that he within it.

SECTION II ANTHROPOLOGY

OPENING ADDRESS BY PROF F MAX MILLER, PRESIDENT OF THE SECTION

If was forty four years ago that for the first and for the last time I was able to take an active part in the meetings of the British Association for the Advancement of Science. It was at British Association for the Advancement of Science I was at Oxf.ord, in 1847, when I read a paper on the "Relation of Ben-gal to the Asyan and Aboriginal Languages of India," which received the honour of being published in full in the Transac-tions of the Association for that year I have often regretted that absence from England and pressure of work have prevented me year after year from participating in the meetings of the Asso-ciation Bath, being a citizen of two countries—of Germany by hirth, of England by adoption-my long vacations have gener ally drawn me away to the Continent, so that to my great regret I wonder whether any of those who were present at that bril-

liant meeting at Oxford in 1847 are present here to-day I almost doubt it. Our President then was Sir Robert Inglis, who will doubt it. Our Fresident then was Sir Robert ingits, who will always be known in the annals of English history as having been preferred to Sir Robert Peel as Member of Parliament for the University of Oxford. Among other celebrities of the day I remember Sir Roderick Murchison, Sir David Brewster, Dean Buckland, Sir Charles Lyell, Prof. Sedgwiek, Prof Owen, and many more—a galaxy of stars, all set or setting. Young many more—a galaxy of stars, all set or setting. \(\)
Mr. Ruskin acted as Secretary to the Geological Section Section was then not even recognized as yet as a Section. We ranked as a sub-Section only of Section D. Lorlogy and Bolary ranked as a sub-Section only of Section 13, Lordings and Hadary We remained in that subordinate position till 1831, when we became Section E, under the name of Gorgeraphy and Ethnology. From 1869, however, Ethnology seems almost to have distilled the substitution of the substitution of

General I was invited to join the meeting by Bansen, then Prussian Minister in London, who also brought with him his Iriend Dr. Karl Meyer, the Celuc scholar Prince Albert was

present at our debates, so was Prince Louis Lucien Bonaparte.

Our Ethnologueal sub-Section was then most popular, and
When looking goos more through the debates carried on in
our Section in 1847, I was very much surprised when I aws how
very like the questions which occupy as to-day are to those
which we discussed in 1847. I do not mean to say that there
has been no selvance in our science. Far from it. The advance has been no advance in our science. Far from it. The advance of linguistic, ethnological, anthropological, and biological studies, all of which claim a hearing in our Section, has been most rapid. Still that advance has been steady and austained, most rapid Sill that advance has been steady and austained, there has been no cataclyam, no deluge, no break in the advancement of our science, and nothing seems to me to prove its healthy growth more clearly than this uninterrupted continuity, which unites the past with the present, and will, I hope, unlie the present with the future.

No paper is in that respect more interesting to read than the address which Bunsen prepared for the meeting in 1847, and which you will find in the Transactions of that year. Its title is "On the Results of the recent Egyptian Researches in

life is "On the Kesuit of the recent Egyptian Kesearches in reference to Assate and African Litnology, and the Classifica-tion what this title would lead you to expect. There are peed deal more than what this title would lead you to expect. There are pessades in it which are truly prophetic, and which show that, if prophety is possible anywhere, it is possible, any, it ought to be possible, in the temple of Science, and under the

inspiring influence of knowledge and love of truth
Allow me to dwell for a little while on this remarkable pape Allow me to dwell for a hitle while on hits remarkable paper Is it rue, we have travelled no kin this bisuare neural amost to belong to accord history. This very year is the hundredth ambits being close accord history. This very year is the hundredth ambits being celebrated in several towns of Germany. In England also hit memory should not be forgotten. No one, not being an Englishman by both, could, I believe, have loved this county more warmly, and could have worked more heartily than Bluesten did to bring about that frendship between Englishman Bussen did to bring about that frendship between Englishman Bussen did to bring about that frendship between Englishman Bussen did to bring about that frendship between Englishman Bussen did to bring about that frendship between Englishman Bussen did to bring about that frendship between Englishman Bussen did to bring about that frendship between Englishman Bussen did to bring about that frendship between Englishman Bussen did not be the second that the second tha than bursen due to oring anough that triendship between Eng-land and Cermany which must for ever remain the corner-stone of the peace of Europe, and the une quid non of that advance-ment of science to which our Association is devoted. His house in Carlton Terrace was a true international academy, open to all who had something to say, something worth listen ing to, a kind of sanctuary against vulgarity in high places, a neutral ground where the best representatives of all countries were welcome and felt at home. But this also belongs to were welcome and left at nome Datt this also belongs to ancient listory. And yet, when we read Bunsen's paper, delivered in 1847, it does not read like ancient history. It deals with the problems which are still in the foreground, and if it could be delivered again to-day by that genial representative of German learning, it would jouse the same interest, provoke the same applause, and possibly the same opposition also, which it roused nearly half a century ago Let me give you a few in-stances of what I mean.

stances of what I mean.
We must remember that Darwin's "Origin of Species" was
published in 1859, hit "Decent of Man in 1871. But here in
causes in the question of the possible direction of man from some
unknown annual. He traces the history of that question back
to Frederick the Great, and quotes his memorable asswer to
D'Alembert. Frederick the Great, tyou know, was not disthe control of the possible of the control of D'Alemiert. Frederick the Great, you know, was not dis-turbed by any qual-mot orthodoxy. 'In my knegdom,' he used to say, "everybody may save his sool according to his own fashion." But when D'Alembert wished him to make what he called the salts merials from monkey to man, Frederick the called the salts merials from monkey to man, Frederick the when the salts of the salts of the salts of the salts of the which no sunnal can clear, ow which, at all events, not, and that with all the likeness of their bodily organs there is a barrier which no sunnal can clear, ow which, at all events, no animal has any set cleared. And what does Bussen himself consider the real lawrier between man and beats." 'Il is a language,' the says, except man." In natwer to the argument that, given only a sufficient number of years, a transition by imprecipible degrees except man." In answer to the argument that, given only a sufficient number of years, a transition by imprecipible degree from animal circs to articolate language is at least conceivable, the says, —"Those who hold that to pinson have never been able to show the possibility of the first step. They attempt to veil their inability by the easy but fruitless assumption of an infairte space of time, dettined to explain the gradual development of animals into men, as if millions of years could supply the want of the sgent necessary for the first movement, for the first step, in the line of progress. No numbers can effect a logical impossibility.

How, indeed, could reason spring out ot a state which is destitute of reason? How can speech, the expression of thought, develop itself, in a year, or in millions of years, out of inarti-culate sounds, which express feelings of pleasure, pain, and

appetite?"

If then appeals to Wilhelm von Humboldt, whom he truly

of almost all He then appeals to Withelm on Humboldt, whom he truly calls the greatest and most acute annioms of almost all human speech Humboldt goes so far as to say -- "Hather than sasign to all language a uniform and mechanical march that would lead them step by step from the grossest beginnings to their highest preference, I should embrace the opinion of those who sarribe the origin of language to an immediate revelation of the step of the ste which shines through all idioms, even the most imperfect and

Bunsen then sums up by saying: "To reproduce Monboddo's theory in our days, after Kant and his followers, is a sorry ana chronism, and I therefore regret that so low a view should have been taken of the subject lately in an English work of much correct and comprehensive reflection and research respecting correct and comprehensive renection and research respecting matural science." This remark refers, of course, to the "Vestiges of Creation" (see an article in the Edinburgh Review, July, 1843), which was then producing the same commotion which Darwin's "Origin of Species" produced in 1859
Bunnen was by no means unaware that in the vocal expression

of feelings, whether of joy or pain, and in the imitation of external sounds, animals are on a level with man "I believe with Kant," he says, "that the formation of ideas or notions, embodied in words, presupposes the action of the senses and impressions made by outward objects on the mind But," he adds, "what enables us to see the genus in the individual, the impressions name of source and source and the individual, the adds, "what enables us to see the genus in the individual, the whole in the many, and to form a word by connecting a subject with a predicate, is the power of the mind, and of this the brute

creation exhibits no trace."

You know how for a time, and chiefy owing to Darwin's perdominating influence, every concernable effect was made to
exhibit the control of the control of the control
beats, and to treat language as a wanhung line in the medial
evolution of animal and man. It required some courage at times
to stand up against the authority of Darwin, but at present
all serious thinkers agree, I believe, with Bussen, that no
animal has developed what we mean by rational language, as distinct from mere utterances of pleasure or pain, from imitation of sounds and from communication by means of various signs, a of sounds and trom communication by means of various signs, a subject that has listely been treated with great fullness by my learned friend Prof. Romanes in his "Mental Evolution of Man" Still, if all true science is based on facts, the fact remains that no animal has ever formed what we mean by a language, and we are fully justified, therefore, in holding with Bunsen and Humboldt, as against Darwin and Prof Romanes, that there is a specific difference between the human animal and all other animals, and that that difference consists in language as the outward manifestation of what the Greeks meant by Logor.

, Another question which occupies the attention of our leading Another question which occupies the attention of our reading anthropologists is the proper use to be made of the languages, customs, laws, and religious ideas of so-called sevages. Some, as you know, look upon these modern savages as representing human nature in its most primitive state, while others treat them. as representing the lowest degeneracy into which human nature may ank. Here, too, we have learnt to distinguish We know that certain races have had a very slow development, and may, therefore, have preserved some traces of those ample institutions. which are supposed to be characteristic of primitive life. But we also know that other races have degenerated and are degenerat-ing even now. If we hold that the human race forms but one species, we cannot, of course, admit that the ancestors even of the most savage tribes, say of the Australians, came into the word one day later than the ancestors of the Greeks, or that they passed through few or evolution than their more favoured brethren. The whole of humanity would be of exactly the hand the state of the world one day later than the ancestors of the Greeks, or that

savage is justly disclaimed as the prototype of natural, original man; for linguistic inquiry shows that the languages of savages are degraded and decaying fragments of nobler formations.

I know well that in unreservedly adopting Bannen's opinion on this point sho I run counter to the teaching of such well-known writers as Sir John Lubbock, Reclus, and others. It might be supposed that Mr Herbert Speacer also looked upon savages as representing the primitive state of mankind But if he ever did so, he certainly does so no longer, and there is nothing I admire so much in Mr. Herbert Spencer as this simple nothing I admire so mucu in Air, I retrieft spencer as times include love of truth, which makes him confess openly whenever he has seen occasion to change his views "What terms and what conceptions are truly primitive," he writes, "would be easy if we had an account of truly primitive men. But there are sundry we mad an account of truty primitive men. But there are sainly reasons for suspecting that existing men of the lowest type form-ing social groups of the simplest kind do not exemplify men. men as ing social groups of the simplest state of them, if not all, had ancestors in a higher state" (Open Court, No. 205, p. 2896)

Most important also is a hint which Bunsen gives that the

students of language should follow the same method which has been followed with so much success in geology, that they should been followed with so much success in georogy, and then apply been with studying the modern strata of speech, and then apply the principles, discovered there, to the lower or less accessible strata It is true that the same suggestion had been made by strata It is true that the same suggestion has been made by Leibniz, but many suggestions are made and are forgotten again, and the merit of rediscovering an old truth is often as great as the discovery of a new truth This is what Bunven said: "In order to arrive at the law which we are endeayouring to find (the law of the development of language) let us first assume, as geology does, that the same principles which we see working in the (recent) development were also at work at the very beginning, modified in degree and in form, but essentially the same in kind We know how fruitful this suggestion has proved, and how We know how fruitful this suggestion has proved, and now much light an accurate valy of modern languages and of spoken dialects, has thrown on some of the darkest problems of the scenece of language. But fifty years ago it was Sanakit only, or Hebrew, or Chinese, that seemed to daserve the attention of the students of comparative philology. Still more important is Bunner's next remark, that language legins with the sentence, and that in the beginning each word was a sentence in stell. has used in the originating each word was a sentence in itself. This view also has found strong supporters at a later time—for instance, my friend Frof Snyce—though at the time we are speaking of it was hardly thought of I must here once more quote Euneen's own words. "The supreme law of progress in all language thows itself to be the progress from the substantial an inaguage snows itscil to be the progress from the shoutantal isolated word, as an undeveloped expression of a whole sentence, towards such a construction of language as makes every single word subservient to the general idea of a sentence, and shapes, modifies, and dissolves it accordingly."

modifies, and dissolves it accordingly."

And again "Every sound in language must originally have heen significative of something. The unity of sound (file syllable, pure or consonantised) must therefore originally have corresponded to a unity of conscious plastic thought, and every thought must have had a real or substantial object of percep.

corresponds to a turn of conscious principal control c fires, and unfares The modern school maintained that there crusted entire roots by themselves no suffice, preferee, and infared by themselves, and that the theory of aggluttation—understanding the control of the cont

and therefore significative, that they are the remnants of pre-dicative or demonstrative words. It is true we cannot always prove this as clearly as in the case of such words as hard-shap, wors-dom, man hood, where hood can be traced back to hold, instruction, must hard, where Asset can be traced back to Add, which in Anglo Savion crassis as an independent word, meaning which in Anglo Savion crassis as an independent word, meaning in a determinant, claim-resent, continuer to exist by stell, as when we say in Sapansh dorse, concess y dependented: I as perfectly tree that the Preach, when they say that a hammer shill domedic originally the Latin mostel, "with a simil "—and give it to their adjective Instal Here the new school has done good service in showing the working of that united of analogy which continues the same of the same properties of the same of the same properties." is a most important element in the historical development of human speech. One compound was formed in which mente retained its own meaning; for instance, forti menti, But when this had come to mean bravely, and no brave mind But when this must could be installed. In more, the working of analogy began, and if fortement, from fort, could mean "bravely," then why not louidment, from lourd, "heavily?" But in the end there is no escape from Bunsen's fundamental principle that everything in language was originally language—that is, was significative, was substantial, was material
—before it became purely formal

But it is not only with regard to these general problems that But it is not only with regard to these general problems that But it is not only with regard to the general problems for some of a superior of the superior of the superior of the right when many of his contemporaries, and even successor, were evong I has long been a question, for mutance, whether the Armenan language belonged to the Iranic branch of the Sunkrit, Fernan, or Greek Bunnen, in \$45, retarded Armenan as a separate branch of Aryan speech, and that it is so was proved by Prof. Histochaman in \$63, such whether his names to the superior branch of Aryan speech, and that it is so was to the superior branch of Aryan speech, and that it is so was to the superior branch of the superior superior superior branch superior sup

proved by Prof. Hulschmann in 1833.
Again, three has been a long onclusive symbolic the language Again, three has been a long onclusive or the Inneh Bunch. Dr. Trumpp timed to thow that it belonged, by certain peculiaries, to the Indice or Sanakrine branch. Prof. Darmeelster has proved but lately that it shares its most essential characteristics of the Indice of t

I hope you will forgive me for having detained you so long ith a mere retrospect. I could not deny myself the satisfaction with a mere retrospect with a mere reirospect of paying this tribute of grantitude and respect to my departed friend, Baron Bunsen To have known him belongs to the most cherished ecollections of my life. But though I am myself an old man-much older than Bunsen was at our meeting in 1847—do not suppose that I came here as a mere landator tempora act. Cerianly not. If one trea to recall what anthropology was in 1847, and then considers what it is now, antiropology was in 1247, and tien considers was it is now, its progress seems most marvellous I do not think so much of the new materials which liave been collected from all parts of the world. These last fifty years have been an age of discovery in Africa, in Central Asia, in America, in Polynesia, and in Austialia, such as can hardly be matched in any previous

But what seems to me even more important than the mere increase of material is the new spirit in which anthropology has been studied during the last generation. I do not mean to depreciate the labours of so called dilettants After all, dilettanti are lovers of knowledge, and in a sludy such as the study of anthropology the labours of these volunteers, or franc tircurs, have often proved most valuable. But the study of man in every part of the world has ceased to be a subject for curroutly only. It has been raised to the dignity, but also to currosity only It has been raised to the dignity, but also to the responsibility, of a real science, and it is now guided by principles as strict and as rigorous as any other science—such as zoology, botany, mineralogy, and all the rest Many theories which were very popular fifty years ago are now completely exploded, nay, some of the very principles by which our science was then guided have been discarded. Let me give you one

was the guided have been discissed. Let use give you one instance—princip the most important one—as determining the right direction of anthropological studies, regarded that the usely of comparative publiclogy would be in lituee the only ask foundation for the study of anthropology. Largustic ethnology was a very favourite term used by Bunnes, Prichard, Latham, and others. It was, in fact, the chief purpose of Banner's paper to show that the whole of manified could be classified according

to language I protested against this view at the time, and in to language I protested against this view at the time, and in 1853; I published my formal protest in a letter to Banaen, "On the Iuranam Languages" In a chapter called "Ethnology sorrus Phosology" I called, if not for a complete divorce, at least for a judicial separation between the study of philodegy and the study of ethnology "Ethnological race," I said, "and phonological race are not commensurate, except in antebistorical times, or, perhaps, at the very dawn of history. With quests and alliances, which, if we may judge from their effects, must have been much more violent in the ethnic than ever in the political periods of history, it is impossible to imagine that race and language should continue to run parallel. The physiologist should pursue his own science, unconcerned about language should pursue his own science, unconcerned about language. Let him see how far the skulls, or the hair, or the colour, or the colour of their words his trace shall be considered to the colour of their words his colour of the colour of their words his colour of their words have been considered to the colour of their words have been considered to the colour of their words have been considered to the colour of their words have been considered to the colour of their words have been colour of their words h His system must not be altered to suit another system. There is a better solution both for his difficulties and for those of the phonologist inhan mutual compromise. The phonologist should collect his evidence, arrange his classes, divide and combine in no Blumenbach had ever looked at skulls, as if no Camper had ever measured facial angles, as if no Owen had ever examined the basis of a cronium. His evidence is the evidence campen of the basis of a cronium. His evidence is the evidence had ever measured takin man. His evidence is the evidence camined the basis of a cranium. His evidence is the evidence of language, and nothing else, this he must follow, even though the control of political. There ought of language, and nothing size, this ne must follow, even though in the teeth of history, physical or political. There ought to be no compromise between ethnological and phonological science. It is only by stating the glaring contradictions between the two that truth cau be elected.

the two that truth can be clusted "a cappace, any, cardonly Al fini my protest met with cappace, any, cardonly Al fini my protest met with cappace, any, cardonly and the cappace and the capp Theorem be ween nation; and tanguages. Into a the book of Daniel, in 4, "the herald cred about. Opeople, nations, and languages." Why then should we not distinguish between nations and languages? But to put an end to every possible misunderstanding, I declared at last that to speak of "an Ayran skull would be as great a monstrosity as to speak of a dolicho-

cephalic language

I do not mean to say that this old heresy, which went by the name of linguistic ethnology, is at present entirely extinct. But among all serious students, whether physiologists or philologists, it is by this time recognized that the divorce between ethnology and philology, granted if only for incom-patibility of temper, has been productive of nothing but good. Instead of attempting to classify mankind as a whole, students

are now engaged in classing skulls, in classing hair, and teeth, and skin Many solid results have been secured by these special researches, but, as yet, no two classifications, based on these characteristics, have been made to run parallel

The most natural classification is, no doubt, that according to the colour of the skin. This gives us a black, a brown, a yellow, a red, and a white race, with several subdivision. This classification has often been despised as unscientific; but it may still turn out far more valuable-than is at present sup-

The next classification is that by the colour of the eyes, as black, brown, bazel, grey, and blue This subject also has attracted much attention of late, and, within certain limits, the results have proved very valuable.

The most favourite classification, however, has always been The most favourite classification, nowever, has always occur
that according to the skulls. The skull, as the shell of the brain,
has by many students been supposed to betray something of
the spiritual essence of man, and who can doubt that the
general features of the skull, if taken in large averages, do correspond to the general features of human character? have only to look round to see men with heads like a cannon-ball and others with heads like a hawk. This distinction has ball and others with heads like a hawk. ball and others with heads like a hawk. This distinction has formed the foundation for a more scientific classification into brachyecphalic, distinctionchalic, and mescophalic skulls. The proportion of 80: 100 between the transverse and longitudinal diameter gives us the ordinary or mesocephalic type, the proportion of 75: 100 the dolichocephalic, the proportion of 85: 100 the brach; cephalic type. The extremes are 70 · 100 and 90 : 100

If we examine any large collection of skulls, we have not If we examine any large collection of skulls, we have not much difficulty in arranging them under these three classes, but if after we have done this, we look at the nationality of each kull, we find the most hopeless consistion. Pruner Bey, as Peschel tells us in his "Volkerkunde," has observed brachy-cephalic and doichocephalic skulls in children born of the same mother , and if we consider how many wo nen have been carried motter , and it we consider how many wo sen have been carried away into captivity by Mongolians in their inroads into China, India, and Germany, we cannot feel surprised if we find some longheads among the roundheads of those Central Asiatic hordes.

hordes.

Only we must not adopt the easy expedient of certain anthropologists who, when they find dolichocephal c and brachycephalic skulls in the same tomb, at once jump to the conclusion that they must have belonged to two different races. When, for instance, two dolichocephalic and three brachycephalic skulls were discovered in the same tomb at Alexandernol. we were told at once that this proved nothing as to the simultaneous occurrence of different skulls in the same family; nay, that it proved the very contiary of what it might seem to prove It was clear, we were assued, that the two dolicho cephalic skulls belonged to Arvan chiefs and the three brachycephalic skulls to their non Arvan slaves, who were killed and ouried with their inasters, according to a custom well known to ferodolus. This sounds very learned, but is it really quite Herodotus

sides the general division of skulls into dolichocephalic. brachycephalic, and mesocephalic, other divisions have been undertaken, according to the height of the skull, and, again, according to the maxillary and the facial angles. This latter division gives us orthognathic, frognithic, and mesognathic skulls

La-tly, according to the peculiar character of the hair, we may distinguish two great divisions, the people with woolly hair (Ulatriches) and people with smooth hair (Lissetriches). The former are subdivided into Tophacom, people with tufts of hair, and Ericcomi, or people with fleecy hair The latter are divided The latter are divided into Euthyroms, straight haired, and Luplocums (not Euploc wavy-haired, as Brinton gives ii), wavy-haired. It has been shown that these peculiarities of the hair depend on the peculiar form of the hnir-tuhes, which, in cross-sections, are found to be either round or elongated in different ways

Now all these classifications, to which several more might be added, those according to the orbits of the eyes, the outlines of the nose, the width of the pelvis, are by themselves extremely useful But few of them only, if any, run strictly parallel It has been said that all dolichocephalic races are prognathic, and have woolly hair. I doubt whether this is true without excep-tion, but, even if it were, it would not allow us to draw any genealogical conclusions from it, because there are certainly many dolichocephalic people who are not woolly haired, as, for instance, the Eskimo, (Brinton's "Races of People," p. 240)

let us consider whether there can he any organic connection between the shape of the skull, the facial angle, the conformation of the hair, of the colour of the skin on one side, and what we call the great families of language on the other. That we speak at all may rightly be called a work of nature, sporn maturale, as Dantes and long ago, but that we speak thas or thus, cost o cost, that, as the same Dante said, depends on our pleasure—that it our work. To imagine, therefore, that as a matter of necessity, or as a matter of fact, doltchocephalic skulls have anything to do with Aiyan, mesocephalic with Semitic, or brachyanything to do with Alyan, mesocephalic with Scientic, or inscrip-cephalic with Turanian speech, is nothing but the wildest random thought, it can convey no rational meaning whatever. We might as well say that all painters are dolichocephalic, and all musicians brach; cephalic, or that all lophocomic imbes work

in gold, and all lissocomic tribes in silver

If anything must be ascribed to prehistoric times, surely the differentiation of the human skull, the human hair, and the differentiation of the human skull, the human hair, and the human skin, would have to be ascribed to that datant period. No one, I believe, has ever maintained that a mesocephalte and a study was spill or differentiated into a diolekoosphale and a Bullet us, for the sake of argument, assume that in prehistore times all dollochechphale people spice Araya, all mesocephale, Semitic, all breinfyerphalic, Turanian languages how would that help us?

So long as we know anything of the ancient Aryan, Semitic-So long as we know anylining of the ancient Aryan, Semitic-and Turanian languages, we find foreign words in cach of them. This proves a very close and historical contact between them for mistance, in Babylonian texts of 3000 u.c., there is the word suddln for cloth made of vegetable fibres, linen That can only be the Sk studdln, the Indus, or saturbara what comes from be the Sk studdin, the Indus, or saturdatase what comes from the Indus I twould be the same word as the Homeric συδώς, fine cloth ("Physical Religion," p 87) In Egyptian we find so many Semaic words that it is difficult to say whether they were borrowed or derived from a common source. I confess I am not convinced, but Egyptologists of high authority assure us that the names of several Aryan peoples, such as the Sicilians and Sardinians, occur in the fourteenth century B C, in the inscriptions of the time of Menculithah I Again, as soon as we know anything of the Turanian languages-Finnish, for instance-we find them full of Arvan words. All this, it may be said, applies to a very recent period in the ancient history of humanity Still, we have no access to endier documents, and humanity Still, we have no access to enrier documents, and we may fairly say that this close contact which existed then

existed, probably, at an earlier time also

If, then, we have no reason to doubt that the ancestors of the people speaking Aryan, Semitic, and Turanini linguages, lived in close proximity, would there not have been marriages between then so long as they lived in peace, and would they not have killed the men and carried off the women in time of war? What, then, would have been the effect of a marriage between a dolichocephalic mother and a brachycephalic father? materials for studying this question of metastage, as the French call it, are too scanty as yet to enable us to speak with confi-But whether the paternal or the insternal type prevailed. or whether their maion gave rise to a new permanent variety, captive woman might be found, after hity or sixty years, spealing the language of the brachycephalic conqueror.

It has been the custom to speak of the early Aryan, Semitic,

and Turanian races as large swarins-as millions pouring from one country into mother. It has been calculated that these early nomads would have required immense tracts of meadow land to keep their flocks, and that it was the search for new pa tures that drove them, by an irresistible force, over the whole inhabitable earth

This may have been so, but it may also have not been so Anyhow, we have a right to suppose that, before there were nullions of human heings, there were at first a few only. We have been told of late that there never was a first man, but we may be allowed to suppo e, at all events, that there were at one time a few first men and a few first women. If, then, the nuxture of blood by marriage and the mixture of language in peace or war took place at that early time, when the world was peopled by some individuals, or by some hundreds, or by some thousands only, think what the necessary result would have been. It has been calculated that it would only require 600 been It has been cutchined that it would only require ooc years to populate the whole earth with the devend units of one couple, the first father being dolichocephalic and the first mother hirechycephalic They mg/th, after a time, all choose to speak an Aryan language, but they could not choose their skulls, but would have to accept them from nature, whether dolichocephalic or brachycephalic

Who, then, would dare at present to lift up a skull and say this skull must have spoken an Aryan language, or lift up a language and say this language must have been spoken by a dolichocephalie skull? \ct. though no serious student would any longer listen to such arguments, it takes a long time before theories that were maintained for a time by serious students, and were then surrendered by them, can be completely eradi cated I shall not touch to-day on the hackneyed question of the "home of the Aryans" except as a warning. There are two quite distinct questions concerning the home of the Aryans.

When students of philology speak of Aryans, they mean by When students of philology speak of Aryans, they mean up Aryan solting but people speaking an Aryan language. They affirm nothing about skulls, skins, hair, and all the rest. Arya with them means speakers of an Aryan language. When, on the contrary, students of physiology speak of dolichocephalic, orthogonable, euthyromic people, they speak of their physiological characteristics only, and affirm nothing whatever about

It is clear, therefore, that the home of the Aryas, in the proper sense of that word, can be determined by linguistic evidence only, while the home of a blue eyed, blond-haired, long skulled, fair-skinned people can be determined by physiological evidence only Any kind of concession or compromise on either side is simply fistal, and has led to nothing but a promisious slaughter of innocests. Separate the two armies, and the whole physicological evidence collected by D'Omalius d'Halloy, Lathaus, and their followers will not fill more than an octato page; while the languistic evidence collected by Bredley and his followers will not amount to more than a few words. Everything else is more day amount to more than a few words.

The physiologust a grateful, no doubt, for any additional skells whose historical antecedents on he firmly established, the philologust is grateful for any additional word that can help to whose historical antecedents on he firmly established, the philologust is grateful for any additional word that can help to the philologust is grateful for any additional word that is possible to argue. They alone have a really scenatife value in the eyes of a scholar, because, if there is any difference of opinion on them, it is possible to come to an agreement. As soon, however, the properties of the properties

My experience during the last forty years have only served to confirm the opinion which I expressed forty years are controlled in the confirm the opinion which I expressed forty years ago, that here ought to be a complete separation between philology and there ought to be a complete separation between philology and the confirmed that the confirmed in the confirmed that th

specific, will be furly welcome to paniologist, quite as much as a tool to the other bearing the property of t

Section In spite of all that I have said against the unholy alliance between physiology and philology, I have felt for years—and I helieve I am now supported in my opinion by all competent anthropologists—that a knowledge of languages must be considered in luture as a una qui non for every authropology.

Anthropology, as yes thou, has necessed or rapidly that it seems to you with "Abda Abs man as an abstrawn jan". So long as anthropology treated only of the anatomy of the human body, any surgeon might have become an excellent anthropologist. But now, when anthropology includes the study of the extract Batta and the seems of the service of the servic

insconnective forms of the mean status and the component interacture. No one would listen to a man describing the peculiarities of the Greek, the Roman, the Jew, the Arab, the Chenese, without knowing their linequages, and being capable often men who have devoted the whole of their life to the study for instance, of Hebrew, differ, not only as to the meaning of certain words and passages, but as to the very character of the Jew, but all Sensitive and passages, but as to the very character of the Jew, but all Sensitive and the study of the study

like all other gods.

You know how widely classical scholars differ on the character of Greeks and Komans, on the meaning of their customs, the control of the classical scholars different to the character of Greeks and Komans, on the meaning of their customs, the their gods. And yet there was a tune, not very long ago, when anthropologists would rely on the descriptions of cassal travellers, who, after spending a few weeks, or even a few years, and even of their regions. It may be said that supplied the people is any Decidedy no, and I am supported in this has yet published his excellent book on the "Mclanesians there Anthropology and Fels-low", spent twenty four years among the Melanesians, learning their dealers, collecting their their characteristics. But what does he say in his preface? "I have felt the truth," he way, "of what Mr Fison, late missionary in that the truth," he way, "of what Mr Fison, late missionary in that the knows all about them, when he has been ten years or samongut them, if he be an observant man, he knows that he

knows very little about them, and so begins to learn."

How few of the books in which we trust with regard to the characteristic poculiarities of savage races have been written by men who have lived among them for ten or twenty years, and who have learnt their languages till they could speak them as well as the nativest themselves.

It is no excuse to say that any traveller who has eyes to see and ears to hear can form a correct estimate of the dougs and saying of savage index. It is not 30, and satisfropologists know and early hear experience of the same throughout the same through the same throughout the same throughout the mage of a young bull. Suppose that the dancer were all stark naded, that after a time they began to fight, and typing about weltering in their blood. Would not a casual traveller have described such awages as worse than the Negroes of Dahomey? Yet these savages were really the Jews, the veller have described such awages as worse than the Negroes of Dahomey? A traveller who contend the measured was Moses We may read the 3nd chapter of Exodus in a very different sense. A traveller who could have sowered with different sense. A traveller who could have sowered with and the same three same

statements of theirs can be used by the antiroprospas tor vary scentific purpose. From the day when this fact was recognized by the highest authorities in anthropology, and was ancicioned by some at least of our Anthropological, Etinological, and Folic-lore Societies, a new specific page, and philology received its right place as the highest day the control of the control of the control proposed our new charter was thus, this it is future no one it to be quoted or relied on as an authority on the customs, traditions, and more

or relied on as an authority on the customs, traditions, and more participating of the religious diese of undervined races who has a religious diese of undervined races who has enable him to converte with them freely on three difficult tablects. No cone would object to this rive when we have to deaf with cyclied and literary nations. But the languages of Africa, and the control of the flowers with the researches of a real Hottentot scholar like Dr. Hahn to When we read the books see the advance that has been made see incagrance that has been made. When we read the books of Bishop Callaway on the Zulu, of William Gill and Edward Tregear on the Polynesians, of Horatio Hale on some of the North American races, we feel at once that we are in safe hands, in the hands of real scholars. Even then we must, of course, remember that their knowledge of the languages cannot compare with that of Bentley, or Hermann, or Burnouf, or Ewald Yet we feel that we cannot go altogether wrong in trusting to their

I venture to go even a step further, and I believe the time will come when no anthropologist will venture to write on any-thing concerning the inner life of man without having himself acquired a knowledge of the language in which that inner life

finds its truest expression

This may seem to be exacting too much, but you have only to look, for instance, at the description given of the customs, the laws, the legends, and the religious convictions of the people of India about a hundred years ago, and before Sanskrit began to be studied, and you will be amazed at the utter caricature that is often given there of the intellectual state of the Brahman compared with what we know of it now from their own literature

And if that is the case with a people like the Indians, who are a civilized race, possessed of an ancient literature, and well within the focus of history for the last two thousand years, what can be expected in the case of really savage races? One can can be expected in the case of really savage races? One can hardly trust one's eyes when one sees the evidence placed before us by men whose good faith cannot be questioned, and who nevertheless contradict each other faily on the most ordinary subjects. We owe to one of our Secretaires, Mr Roth, a most careful collection of all that has been said on the Taumanians by eye-witnesses. Not the least valuable part of this collection of that it opens our eyes to the utter untrustworthiness of the evidence on which the anthropologist has so often had to rely. an article on Mr. Roth's book in NAIURE, I tried to show that there is not one essential feature in the religion of the Tas-manians on which different authorities have not made assertions diametrically opposed to each other. Some say that the Tas-manians have no idea of a Supreme Being, no rites or ceremonies, others call their religion Dualism, a worship of good and evil spirits Some maintain that they had deified the powers of Nature, others that they were Devil-worshippers Some declare their religion to be pure monotheism, combined with belief in the immortality of the soul, the efficacy of prayers and charms. Nay, even the most recent article of faith—the descent of man from some kind of animal—has received a religious sanction among the Tasmanians For Mr Horton, who is not given to joking, tells us that they believed "they were originally formed with talk, and without knee-joints, by a benevolent being, and that another descended from heaven, and, compassionating the sufferers, cut off their tails, and with greass softened their knees?"

I would undertake to show that what applies to the descrip-tions given us of the now extinct race of the Tasmanians applies uong given us or the now extinct race of the tammanneappines of the form to the descriptions of similar all the sawage cance with those to the description of similar all the sawage cance with the contract of the contract o therefore want of sympathy and impossibility of mutual explana-

tion and correction Let me, in conclusion, give you one of the most flagrant instances of how a whole race can be totally misrepresented by men ignorant of their language, and how these misrepresenta-tions are at once removed if travellers acquire a knowledge of the language, and thus have not only eyes to see, but ears to r, tongues to speak, and hearts to feel.

No race has been so cruelly maligned for centuries as the in-habitants of the Andaman Islands. An Arab writer of the ninth

century states that their complexion was frightful, their hair frizzled, their countenance and eyes terrible, their feet very large. and almost a cubit in length, and that they go quite naked.

Marco Polo (about 1285) declared that the inhabitants are no better than wild beasts, and he goes on to say "I assure you all the men of this island of Angamanani have heads like dows. and teeth and eyes likewise, in fact, in the face they are just like big mastiff does."

So long as no one could be found to study their language, there was no appeal from these libels. But when, after the Sepoy mutiny in 1857, it was necessary to find a habitation for a large number of convicts, the Andaman Islands, which had already served as a penal settlement on a smaller scale, became was wrought by this sudden contact between the Andaman Islanders and these civilized Indian convicts was terrible, and population will de out Fortunately one of the English officers (Mr Edward Horace Man) did not shink from the trouble of learning the language spoken by these islanders, and, being a careful observer and perfectly trustworthy, he has given as some accounts of the Andaman aborigines which are real masterpieces of anthropological research If these islanders must be swent of anthropological research 11 these islanders must be swept, away from the face of the earth, they will now, at all events, leave a good name behind them Even their outward appear ance seems to become different in the eyes of a sympathizing observer from what it was to casual traveller. They are, no doubt, a very small race, their average height being 4 feet tof inches But this is almost the only charge brought against them which Mr Man has not been able to rebut their hair. he says, is fine, very closely curled, and friely Their colour is dark, but not absolutely black. Their features possess little of the most marked and coarser peculiarities of the Negro type The projecting laws, the prominent thick lips, the broad and flattened note of the genuine Negro, are so softened down as scarcely to be recognized.

scarcity to De recognized.

But let us hear now what Mr. Man has to tell us about the social, moral, and mellectual qualities of these so called savages, who had been represented to us as canninals, as ignorant of the existence of a destry, as known no marriage, except what by a bold cultimation has been excluded communing and the control of the con

like big mastiffs.

"Before the introduction into the islands of what is called The fore the introduction and the issues of what is caused turpean critication, that of their issues of what is caused turpean critication, that of the interpretation is a consistent leaves of trees. They were ignorant of agriculture, and kept he poultry of domestic animals. Their poticy was hand unde, their clothing very scanty. They were expert swimmers and divers, and able to manufacture well made dug out canoes and outragers. They were ignorant of metals, ignorant, we are told, of producing fire, though they kept a constant supply of burning and smouldering wood. They made use of shells for their tools, had stone hammers and anvils, hows and arrows, harpoons for killing tuitle and fish Such is the fertility of the island that they have abundance and variety of food all the year island that they have abundance and wirely or rood all the year round. Their food was invariably cooked, they drank nothing but water, and they did not smoke. People may call this awaye, the I know many a staving labourer who would gladly exchange the benefits of European civilization for the blessings of such awayery.

blessing of such savagery "
These small islanders, who have always been represented by a certain class of anthropologists as the lowest stratum of humanity, need not fear comparison, so far as their social life is conceined, with races who are called civilized So far from being addicted to what is called by the self-contradictory name of communal marriage, Mr. Man tells us that bigamy, polygamy, polyandry, and divorce are unknown to them, and that the marriage contract, so far from being regarded as a merely temporary contract, to be set aside on account of incompatibility of temper or other such causes, is never dissolved Conjugal fidelity till death is such causes, is never dissolved.

Conjugal nuclify till death is not the exception but the rule, and matrimonal differences, which occur but rarely, are easily settled with or without the intervention of friends. One of the most striking features of their social relations is the marked equality and affection which exist between husband and wife, and the consideration and respect with which women are treated might, with advantage, be emulated by certain classes in our own land. As to cannibalism or infanticide, they are never practised by them. It is easy to say that Mr. Man may be prejudiced in favour of these little savages, whose language he has been also much pains to learn. Fortunately, however, all his statements have lately been confirmed by another authority, Colonel Cadell—the Chief Commissioner of these islands. He is a Victoria Cross man, and not likely to be given to over-much sentimentality. Well, this is what he says of these facer ematifis, with feet a cubit in

length ...

They are merry little people. "It says. "One could not They are merry little people." It says. "One could not them feld in love with them feld in love feld in love with evidence with evidence feld in love feld in lo

delictaces fit for an alderman's table." These are think, which we might suppose anythody who have These are think, which we might suppose anythody who have the suppose anythod the suppose anythod the suppose and suppose and the suppose and suppose and the suppose and s

According to other authorities, some Andamanete look on the tun as tile fountiation of all that is good, the moon as a main power; and they believe in a number of inferior apparts, the spirits of the forest, the water, and the mountain, as agents of the two higher powers. They believe in an evil appit also, who seems to have been originally the ajunt of the storm. Him they try to pacify by songe, or to frighten away with their arrows.

I suppose I need say no more to show how induspensable a study of language is to every student of anthropology. If anthropology is to maintain its high position as a real science, is alliance with languistic studies cannot be too close. Its weakest points have always been those where it trusted to the statements of authorities ignorant of language and of the science of language. Its greatest trumphs have been achieved by men such as Dr. Hahn, Buthops Callaway and Colenno, Dr. W. Gill, and last, not least, Mr. Man, who have combused the minate accuracy of the scholar with the comprehensive grasp of the anthropologist, and were thus mabled to use the key of language to unlock the particularly, of savage religions and mythologist. If this alliance between anthropology and philology becomes real, then, and then only, may we hope to see Busses's prophecy fulfilled, that which has British Associations instituted of the accuracy of the same property of the same proper

Allow me in conclusion once more to quote some prophetic words from the address which Bunsen delivered before our Section in 1847 —

"If man is the apex of the creation, it seems right, on the one sale, that a historical raquery into his origin and development should never be allowed to sever itself from the general body of matural scene, and in particular from physology. But, on the matural scene, and in particular from physology. But, on the which all organic formations tend from the very beginning, if man is at once the mystery and the key of natural scene, if that is the only view of natural scene, worthy of our age, then the only view of natural scene, worthy of our age, then the only view of natural scene, worthy of our age, then the only view of natural scene, worthy of our age, then the only view of natural scene, worthy of our age, then the only view of the order at the physiological are, is the highest branch of that scene for the advancement of which his Association is instituted. It is not an appendix to physiology or to anything else, but it object is, on the contrary, and the contrary of the order of the physiology of the contrary of the order of the

actions of a scientific Association. "Much has been achieved by anthropology to justify these hopes and failfil the prophecies of my old frend Bunsen. Few men live to see the fullificant of their own prophecies, but they leave disciples whose duty it is to keep their memory alive, and thus to preserve that vital continuity of human knowledge which alone enables us to see in the advancement of all science the historical evolution of eternal turns of the properties."

LLECTRICAL STANDARDS

THE Queen's Printers are now issuing the Report dated by 23, 1891 to the President of the Board of Trade, of the Committee appointed to consider the gestion of construcing standards for the measurement of electricity. The Committee included Mr Courtenay Boyle, C.B., Major P. Cardew, R.E., Mr. E. Graves, Mr. W. H. Preece, F.R.S., Sir W. Fhomson, F.R.S., Lord Agyligh, F.R.S., Frof G. Care, Foster, F.R.S., Mr. R. 1. Glasebrook, F.R.S., Dr. John Hopkinson, F.R.S., Pof W.F. Ayton, F.R.S.

In response to an invitation, the following gentlemen attended and gave evidence —On behalf of the Association of Chambers of Commerce, Mr Thomas Parker and Mr High Erst Harmon, no behalf of the Association of the High Erst Harmon, or behalf of the of the London Chamber of Commerce, Mr R. E. Crompton The Committee were indebted to Dr. J. A. Fleming and Dr. A. Murrhead for valuable information and assistance, and they state that they had the advantate that the Committee was start of the Advantate Superintendent of Weights and Measures. The Screenary to the Committee was bir T. W. P. Blomefield,

The following are the resolutions of the Committee :-

Resolutions.

(1) That it is desirable that new denominations of standards for the measurement of electricity should be made and approved by the Marshum of Council as Royal of Toule and the provided in the council of the council o

by Her Majesty in Council as Board of Trade standards.

(2) That the magnitudes of these standards should be determined on the electro magnetic system of measurement with reference to the centimetre as unit of largib, the gramme as unit of mass, and the second as unit of times, and that by the terms centimetre and gramme are meant the standards of those denominations deposited with the Board of Trade.

(3) That the standard of electrical resistance should be denominated the ohm, and should have the value 1,000,000,000 in terms of the centimetre and second.

(4) That the resistance offered to an unvarying electric current

by a column of mercury of a constant cross sectional area of a square millimetre, and of a length of 106'3 centimetres at the temperature of melting see may be adopted as 1 ohm.

(5) That the value of the standard of resistance constructed

(5) That the value of the standard of resustance constructed by a committee of the British Association for the Advancement of Sedence in the years 163 and 1864, and known as the British Association man, may be taken as 1986 of the obm (6) That a maternal standard, countracted in solid metal, and the standard obm.
(7) That for the purpose of replacing the standard, if lost, destroyed, or damaged, and for ordurary use, a huntel number of copies should be constructed, which should be periodically compared with the standard obm.

(8) That resistances constructed in solid metal should be adopted as Board of Trade standards for multiples and submultiples of the ohm.

(9) That the standard of electrical current should be denominated the ampere, and should have the value one tenth

(0) That an unvarying current which, when passed through a solution of nitrate of silver in water, in accordance with the specification attached to this report, deposits silver at the rate of o'cottis of a gramme per second, may be taken as a current of

(11) That an alternating current of I ampere shall mean a current such that the square root of the time average of the square of its strength at each instant in amperes is unity

or its strength at each instant in ampere is inity (12) That instruments constructed on the principle of the balance, in which by the proper disposition of the conductors, forces of attraction and repailson are produced, which depend upon the amount of current passing, and are balanced by knowledges, should be adopted as the Board of Trade standards for

weights, should be adopted as the Board of a rade standards for the measurement of current, whether unwarying or alternating (13) That the standard of electrical pressure should be de-nominated the volt, being the pressure which, if steadily applied to a conductor whose resistance is 1 ohm, will produce a current

(14) That the electrical pressure at a temperature of 62° F between the poles or electrodes of the voltage cell known as between the poles or electrodes of the voltace cell known as Clark's cell, may be taken as not differing from a pressure of 1 433 volts, by more than an amount which will be determined by a sub-committee appointed to investigate the question, who will prepare a specification for the construction and use of the cell (15) That an alternating pressure of 1 volt shall mean a pressure such that the square root of the time average of the square

sure such that the square root of the time average of the square of its value at each instant in volts to unit,

"The first invariants constructed on the propelle of Sir VIII.

"The structure of the structure o ment of pressure, whether unvarying or siternating

We have adopted the system of electrical units originally fined by the British Association for the Advancement of defined by the Science, and we have found in its recent researches, as well as in the deliberations of the International Congress on Electrical Units, held in Paris, valuable guidance for determining the exact magnitudes of the several units of electrical measurement, as well as for the verification of the material standards.

We have stated the relation between the proposed standard ohm and the unit of resistance originally determined by the British Association, and have also stated its relation to the mercurial standard adopted by the International Conference

We find that considerations of practical importance make it undesirable to adopt a mercurial standard, we have, therefore, preferred to adopt a material standard constructed in solid metal.

It appears to us to be necessary that in transactions beat appears to us to be necessary that in transactions between buyer and seller, a legal character should henceforth be assigned to the units of electrical measurement now suggested, and with this view, that the issue of an Order in Council should be recommended, under the Weights and Measures Act, in the form annexed to this report.

Specification referred to in Resolution 10.

In the following specification the term silver voltameter means the arrangement of apparatus by means of which an electric NO. 1140, VOL. 44

current is passed through a colution of nitrate of silver in water. The silver voltameter measures the total electrical quantity which An entirer voltameter measures the total electrical quantity which has passed during the time of the experiment, and by noting this time the time-average of the current, or if the current has been kept constant, the current useff, can be deduced in employing the silver voltameter to measure currents of

about 1 ampere, the following arrangements should be adopted.

The kathode on which the silver is to be denosited should take and a platinum bowl not less than 10 cm in diameter, and from 4 to 5 cm in depth

The anode should be a plate of pure silver some 30 square cm.

in area and 2 or 3 millimetres in thickness

in area and 2 or 3 millimetres in thickness.

This is supported horizontally in the liquid near the top of the solution by a platinum wire passed through holes in the plate at opposite comers. To prevent the dismitgrated ulver which is formed on the anode from falling on to the kathode, the anode should be wrapped round with pure filter paper, secured at the back with sealing wax.

The liquid should consist of a neutral solution of pure silver

nitrate, containing about 15 parts by weight of the nitrate to 85 parts of water

The resistance of the voltameter changes somewhat as the current passes. To prevent these changes having too great an effect on the current, some resistance besides that of the voltameter should be inserted in the circuit. The total metallic resistance of the circuit should not be less than 10 ohms

resistance of the circuit shown not be text than at some Method of making a Measurement—The platinum bowl is washed with nitite acid and distilled water, dred by heat, and then left to cool in a desiccator. When thoroughly dry, it is

then left to cool in a desictator when inortuginy dry, it is weighted carefully

It is nearly filled with the solution, and connected to the rest of the circuit by being placed on a clean copper support must be which a binding screw is attached. This copper support must be insulated

The anode is then immer ed in the solution, so as to be well covered by it, and supported in that position, the connections to the rest of the circuit are made

Contact is made at the key, noting the time of contact current is allowed to pass for not less than half an hour, and the time at which contact is broken is observed. Care must be taken that the clock used is keeping correct time during this interval

The solution is now removed from the lowl, and the deposit is washed with distilled water and left to soak for at least six hours. It is then rinsed successively with distilled water and hours It is then rinsed successively with distilled water and alsolute alcohol, and drade in a hois-in table at a temperature of ahout 160°C. After cooling in a desiccator, it is weighed again. The gain in weight gives the silver deposited. To find the current in amperes, this weight, expressed in grammer, must be divided by the number of seconds during

which the current has been passed, and by 0 001118

The result will be the time-average of the current, if during the interval the current has vaned.

In determining by this method the constant of an instrument the current should be kept as nearly constant as possible, and the readings of the instrument taken at frequent observed inter vals of time. These observations give a curve from which the reading corresponding to the mean current (time average of the current) can be found. The current, as calculated by the voltameter, corresponds to this reading

NOTES

THE International Meteorological Conference at Munich was o, ened on August 26. Dr C Lang, Director of the Bavarian Meteorological Service, was unanimously elected President Prof M. W. Harrington (Chief of the United States Weather Bareau) and Prof E Mascart (Director of the French Meteoralogical Service) were elected Vice Presidents Mr R II Scott (Secretary of the Meteorological Office), Dr F Erk (Munich), and M L Tesserenc de Bort (Paris) were elected Secretaries. Thirty members were present, including representatives from Brazil, Oueensiand, and the United States We hope in a future number to give some account of the proceedings

DR BARCLAY, whose death at Simla has been announced, was working on the Leprosy Commission, and his loss is

described by the Indian press as not only a severe one to Indea, but for the whole scintillic world. His special study was exprogramic borary. He made important researches in dnesses of Indian pitants, and its guared a continuousla repulation. Several of he papers were published in the Linnean Society's Transactions. His great ambition was to solve Indian wheat disease, and he was to have studied coffee disease no Southern Indian next water.

PARTLY owing to Dr. Barclay's death, the Indian Leprose Report will be delayed as hort time. The practical work is virtually completed, and the Draft Report for the Government of India is in type. The chief work now consists in correcting the proofs and the preparation of the plates, maps, and statistics. On the two mansi questions with which they were to deal, vir. the contagousness and hereditary transmission of the dienses, the Commission have come to a manitomiss decision, but their conclusions will not be known till the Report as published by the National Leptone Fig.

THE statutory mith meeting of the International Congress of Orientalists began in the hall of the Inner Temple on Tuesday, when an address was delivered by the Master of St. John's College, Cambridge,

An election to the Coutts Trotter Studentship, at Trinity College, Cambridge, will take place next month. Applieations from candidates must be sent in to the College folice, addressed to the Secretary of the Coutts Trotter Studentship Committee, on or before October 15. The studentship is tenable for two years, and its for enginal research in physiology or in physics.

We are glad to learn that a number of the friends of the late Mr N R Pogeon are thinking of raising a memorial to him in Madris

WITH reference to a recent note, we learn from New South Wales that the Minister for Mines and Agriculture (the Hon. Sydney Smith) has appointed Mr. Niel Harper, formerly a dairy farmer of excellent repute in the South Coast District, to take charge of the travelling dairy, which is to be sent to the different districts of the colony under the control of the Department of Agriculture. It will be necessary for the Agricultural Society, or a local Committee, to provide the requirements of the dairy such as a building suitable for its operations, and giving accommodation sufficient for ten pupils, who will be thoroughly instructed in all dairying operations. Also, for the carriage of the plant to and from the nearest railway station or wharf to the scene of operations, together with the necessary labour to assist in the rough work of cleaning up, &c. The Society, or Committee, will need to provide also a sufficient supply of milk, say about fifty gallons daily, for the operations of the dairy, and plenty of clean water for washing butter and cleaning up. Each Society, or Committee, undertaking to furnish these requirements will be entitled to nominate at least ten pupils (either male or female) for the full course of instruction in dairy operations, who will afterwards be examined with a view to receiving a dairy certificate in the event of their showing a satisfactory knowledge of the course of instruction Of course the general public will be admitted to see all the operations of the dairy, which will work for ten days at each place where set up. All district Societies and Committees desiring to have the benefit of this course of instruction for their localities should make early application to the Director of Agriculture, from whom regulations and instructions can be obtained. Is our Minister of Agriculture doing anything similar?

At the request of the Russian Ambassador in London, the Secretary of State for India has asked the Government of India to afford facilities to Prof. Tichomiroff, who is about to visit

certain parts of India, Ceylon, and China, with the view of studying the administration of botanical gardens and cinchona plantations, and to M. Gondatti, who is about to study tea and silkworm cultivation in India, Ceylon, and China

CAPTAIN WAHAB, R E, will have charge of a party which is to make a survey of the country round Aden during the coming winter.

MR. GRIESBACH, of the Geological Survey of India, has proceeded with a survey party to Upper Burmah, where he will remain about two years to examine thoroughly the geological condition of the country.

AN important resolution of the Government of India on the reorganisation of the superior staff of the Indian Forest Department has been sissed. At an extra yearly cost of three lakeh or injurye, the Importal and Promoral Services are to be separated. The Importal is to be recruited solely indice revenant with the Section of Siste, and the average pay raised 6 per cent. The Promincal Service gives 155 appointments, up to 600 rispects a month, to natives of India. The Forest Department is the first to introduce a complete scheme under the Public Service Com-

NINE members of the Aitt Arctic Expedition arrived at Haliata, N S, on August 30. The Expedition reached 77 43 'N, and 70 20' W They have brought with them immense collections of flowers, herin, and butterflees, some of which were previously unknown. It is stated that "they found all the published charts of Greenland to be incorrect."

Expansions for the production of artificial rain are now being made in Texas. They are conducted by menthers of the Nignal Copp, acting under the direction of the Minister of Agriculture, and have been undertaken in accordance with a vote of the United State's Congress. Alequate: reports on the subject have not yet reached that country, but it is claimed that the experiments have been attended by remarkable success.

Ms GYOKOE FORBER, writing to the Times on August 31, gave the following account of a meteor which he had seen at Madenhead on the previous evening at 8h. 32m.—"It was madenhead on the previous evening at 8h. 32m.—"It was the properties that 15 miles and 11 miles that of three seconds from the time. I first saw it, it steadly increasing in its rear part when at its triphter—re just before extinction. There was no train, the luminosity not extending more than the state of the state o

In the Meteorologische Zeitschrift for July, Prof H. Mohn discusses the present methods of reduction of meteorological observations: after the completion of twenty-five years of observations at the Nors egian stations, he has decided upon making certain more or less important alterations, commencing from January I last (1) As regards pressure, to introduce the correction for standard gravity at sea-level, in latitude 45°, which amounts to 0'16 inch between the equator and the Poles, and to as much as 0 03 inch between two extreme stations of the Norwegian system And to apply a correction due to diurnal range (to be determined from bourly observations) to the monthly means obtained and published from two or three observations daily. (2) Similarly, for temperature and humidity, to apply corrections to the published monthly values obtained from two or three daily observations. He fully explains the methods he has adopted for obtaining the corrections to be applied, and we thin't the matter is worthy of the attention of meteorologists who publish their results Prof. W. von Benold gives an interesting summary of his paper on the theory of cyclones, which he laid before the Berlin Aendemy in December last, and in which he treated of the more recent views regarding the laws of atmospheric circulation, he also refers to various points which have to be dealt with for the further advancement of the scene.

M. LAKEASTER has recently indicated in Cut of Test of the divergences from normal temperature in Largo in the five years 1856-500. It appears (and as shown in a map) that the scatter of the "shaind of cold" like so over the north of France, the world of Belgium, and the most seatern parts of Germany. From this centre is the cold decreases pretty regularly counseled as all selects to keed decreases pretty regularly counseled as all selects as a nearly created the of the divergence, which can be suffered to the selection of the s

SR H MORIZE, astronomer at the Observatory of Rio de Isneiro, has just published a "Sketch of the Climatology of Brazil," which will be welcome to meteorologists, as hitherto systematic observations have only been published for a very few points of that immense country, covering 30° of latitude. The present sketch has been drawn up mainly from the observations of travellers and private observers. We can only extract a few brief notes Thunderstorms are very frequent all along the coast, and are mostly harmless, regular cyclones are very rare-the most dangerous winds are the pamperos, which blow from the south-west, and have been fully described by the late Admiral Fitz-Roy, and a still more rare and dangerous wind which blows from the south east. As regards temperature, the author has divided the country into three zones, and some valuable data are given for various localities. Parts of the country are subject to prolonged drought, it is said that at Pernambuco no rain fell during the whole year 1702, and a third of the population died fron its effects; droughts have recurred during the present century with some regularity, the last being in the year 1888-89 The most complete series of observations is that for Rio de Janeiro, which dates from 1781, with occasional interruptions The highest shade temperature was 99"5 in November 1883, and the lowest 50° 4 in September 1882 There are also good series of observations for Rio Grande do Sul and São Paulo

ONE of the most important contributions made of late years to our knowledge of the embryology of flowering plants is to be found in a paper by a lady, Mdlle, C. Sokolowa, in the Bulletin of the Imperial Society of Naturalists of Moscow. It relates especially to the formation of the endosperm within the embryo sae of Gymnosperms, the particulars of which are described in great detail. The process is somewhat intermediate between that of ordinary cell-division and that known as free cell-forma tion. It is a group of short cells belonging to the parietal layer of this endosperm that ultimately develop into the corpuscles or secondary embryo sacs, the homologues of the archegones of Vascular Cryptogams. In the tendency displayed by Pinus and Cephalotaxus towards the early differentiation of these cells. Mdlle. Sokolowa sees the foreshadowing of the process which is universal in Angiosperms, the formation of the embryonic v.sicles before that of the endosperm Ephedra exhibits a still closer approximation in this respect to Angiosperms than to the Conifers. In the same number of the Bulletin is an interesting and important paper by Prof. Goroschankin on the "Structure and Reproduction of Chlamydomonas." The former paper is written in French, the latter in German.

NO. 1140, VOL. 44]

The surery of the cañon of the Colorado, has now been completed, and Mr. R. B. Station has given a fall account of it in the American Engineering New In spite of the great depths of the cañon and the clifts of anadotione, marble, and granite compoung it, a railway can in his opinion be built through it without much tunnelling, thus opening up some of the grandest seenery of the world. In many places the cañon expands into wide valleys, and even where it in rows there are terraces along the sides like the "parallel roads" of Given Roy in Sextland, which seem designed by nature, for track and rail. The tributaries which entire the cañon laterally are as a rule small, and can be easily bridged. The distance of 1019 miles through the cañon district will only comprise 20 miles of tunnelling and 99 miles of grantee cutting.

At the meeting of the Linnean Society of New South Wales, on June 24, Mr. C Darley shibited some very large examples of the shells of the mud syster (Ostriva shifts), war, angan) obtained during dredging operations in Rocale Bay, Sydiney Harbour, They occur in great numbers at a digth of to 1a feet below low water mark beneath a layer of black mud 3 to 4 feet back, and are much larger than specimen now to be found living in the harbour. The two valvas of one pair weigh 3 pounds 1 a ounces, and measure about 8 & 6 inches;

IN Nature Notes for August Mr. R T. Lewis, on the authority of a correspondent in whose trustworthiness he has entire confidence, gives a curlous account of the appreciation with which the song of the Cicada is heard by insects other than those of its own genus. The correspondent has frequently observed in Natal that when the Cicada is singing at its loudest, in the hottest portion of the day, it is attended by a number of other insects with lovely, gauze-like, iridescent wings, whose demeanour has left no doubt on his mind that the music is the attraction The Cicada, when singing, usually stations itself upon the trunk of a tree with its head uppermost, and the insects in question, to the number sometimes of fifteen or sixteen form themselves into a rough semicircle at a short distance around its head. During a performance one of the insects was observed occasionally to approach the Cicada and to touch it upon its front leg or antennæ, which proceeding was resented by a vigorous stroke of the foot by the Cicada, without, however, any cessation of its song The insects composing the audience are extremely active, and so wary that they take flight at the least alarm on the too near approach of any intruder. Some of them, however, have been captured, and on examination these " proved to belong to the same family as that most beautiful of British insects-the lace-wing fly, which, indeed, they closely resemble except as to size, their measurement across the expanded wings being a little over two inches, they have since been identified by Mr. Kirby at the British Museum as Nothochrysa gigantea.

ACCORDING to a telegram through Dalucal's agency from Accountry, the Canadana Facolic sensent "Open," which arrived therefrom Hong Kong and Vokohama on August 30, has reported a termife typhone ast Kodo on the fish that All the steamers in the harbour dragged their anchors, and many native boats were cast abstroad their cives were drowned. A Gertana stemaship was driven subnor and eight of the crew were drowned, and an Indiana burque. Surgleir as werecked, and all no hoard arong natives and foreigness it as believed that a 50 lives were lost. Her Majesty's gusboat Thord sank. Altogether among natives and foreigness it as believed that a 50 lives were lost. The wind did much danange imbore. In one coast town forty-five penagoa were killed by falling houses.

THE Science and Art Department has issued its Directory (revised to June 1891), with regulations for establishing and conducting science and art schools and classes.

This University College, Bratol, has issued its Calendar for the session 1891-92. While the College supplies for persons of either see above the ordinary school age the means of continuing, their studies in science, languages, history, and literature, it claims especially to afford appropriate and systematic instruction in those branches of applied science which are more nearly connected with the arts and manufactures.

Six WILLIAM MAGGREGOR, Governor of British New Counce, recently scended Mount Vale, or Kowo, as he prefers to call ut. The Kowo range is volcante and isolated from the man chain, of which Mount. Owen Stanley is the cellmantion. The Kowo range is under 1,000 feet high, and it wooded to the very summit. Native tracks lead through the forest to the top of Mount Vulle, on the south-west front of which there is a magnificent series of cassades, having a height of good feet in all. A new river and in new lake were also discovered, but the animal tile of the region was far from shoundard.

The last Bulletin of the Geographical Society of the United Datas contains an interesting puper on the curvos alsowers of human remains under the Tuolsame Table Mountain of Cahernia Bones of mea and granding instruments were there found by Prof. Whitney, embedded in surficeose gravel under law at the foot of the mountain. Re names of plants belonging to the Tertiary age, and the bones of extinct Mammalia, such as the rhinocrose of the West and the American survivolon, are also met with in the same strata. Featles, morters, and broken pear heads are the most remarkable of the implements disposed the data of the most remarkable of the implements dis-

From the last Report of the Council of the North China Annite Sectify OShanghas we learn that the printers have now in hand a most valuable work by Dr. Breichneider on the Botany of the Chinese Claisse, "the public atom of which, on account of its length and technical difficulties, has been much closed as the council of the length and technical difficulties, has been much closed. Mr. Faber has undertaken the difficult insk of correcting the printer's proofs and adding many notes, which will reader the work the most comprehensive and useful book which hay tel appeared on Chinnese boats on China School and the system of the contract of the council of the contract of the council of the coun

THE new number of the Internationales Aschio Jur Ethnographs, (Band w, Heft 4) opens with an interesting paper by Prof. A. C. Haddon, on the Tugern head hunters of New Guinea Mr J J. M. de Groot has an article on the wedding garments of a Chinese woman, and Dr Julius Jacobs discusses (in Dutch) the closes of Dr Ploss on the ongoin of erreamenton.

MESSEN WEST, NEWBAN, AND CO, have reprinted from the Journal of Relating for 1891, a "Key to the Genera and Species of British Mosses," by the Rev II G Jameson. The author explains that his work is not intended to take the place of a more delatile text book, but interely to serve as a clae by which the student may ascertain as what part of his book he shald look for the description of any unknown specimen.

Wa have received a Report on Astronomical Observations for 1886, by George H Boehmer Directors of observatories, and astronomics generally, are earnestly requested by Mr. Boehmer to criticize his work freely, and to send him such corrections and additions as may seem to them necessary or destrable

MESSES W. WESLEY AND SON have published a catalogue of botanical books which they are offering for sole.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (Macacus synomolgus ?) from India, a Pinche Monkey (Midas unipus d) from New Granada, presented by Mr. H. Wather; a Roseate Cockatoo.

On August 7, 1891, I re observed the spot with a 10 inchedency power zgis, and found it will defined and fairly conspicuous. It passed the central meridam of the planet at 11h, 2ms, so that it followed Marth's zero mendiam (System Lions by Mr. A. S. Williams in May last, which placed the top of a minute behand the zero mendiam. Mr Marth's compatations are to be found in the Monthly Notices for March Debetonets.

Agast from the red spot, it is desirable that the white spots nor the planet's equator, and the smaller markings which verge the northern sade of the north equatorial belt, should be assoliated the same of the spot of the same spot of the same

variation apparently affects the course equational zone, and it will be important to dete mine the exact extent of it, and whether it is asstained in the present year. The thinges of velocity alluded to are exercely progressive in the same direction, we may expect to find an acceleration sooner or later to compensate for the relatively slow movement of the spots in the few past years It is not unlikely that the various marking.

compensate for the relatively slow movement of the spots in the few past years. It is not unlikely that the various markings show oscillations of speed recurring at uniform intervals. Students of this interesting plante will find abundance of materials to collate and discuss. There is ample evidence of materials to collate and discuss. There is ample evidence of the student of the speed of the student of the student plant plant plant plant planted that the speed of the more durable markings appearingly suffer temporary obscuration by vaporous masses suspended above them in the Jowass atmosphere. In the disposition of the belts is also liable to changes, though not so rapadly as is generally supposed, for many of the altigued variations have been due to differences in telescopic definition or to tapid totation of the disposition of the student of the disposition of the student of

SCIENTIFIC SERIALS

American Found of Science, Aurust - Some of the American Journal of Science, August — Joine of the features of non volcanic igneous ejections, as illustrated in the four "Rocks" of the New Haven region, West Rick, Pine Rock, Mile Rock, and East Rock, by James D. Dana. A few of the conclusions arrived at from the observations recorded in this paper are that igneous cruptions occurred in the New Haven region after the sandstone had been noturned. The hund rock forced its way between layers of the sandstone, and lifted it up where the pressure of the rock was not too great to prevent the upheaval. This intrusive action was favoured by the fact the upheaval. This intrusive action was favoured by the fact that the fissure supplying the lava was inclined in the same direction as the layers of the uplifted sandstone. And the logi-tion of the underlying scluss did not determine the course and dip of the upply fissures. The paper is illustrated by several excellent photographs of the formations investigated— Note on a reconnaissance of the Quachita mountain system in Indian territory, by Robert T Hill.—The continuity of solid and liquid, by Cail Barus By means of the simple airangement described in this paper, the author is able to obtain at once the isothermals and isomestics, and therefore the mometries, both for the solid and liquid states of the substances experimented The relation of solidification and fusion to pressure and the pressure changes of the isothermal specific volumes of solid the pressure changes or the isomerous specine volumes of solution and liquid at the solutioning and melting points can all o'be determined. And from such results the character of fusion and the probable position of critical and transitional points can be found. The author has as yet only investigated the biliavour of naphitaliene by his method, but the whole work, throws considerable light upon the relation of pressure to phenomena of saterable light upon the relation of pressure to pnenomena of fusion and solution—Note on the appliation of Utah and Colorado, by George H Stone. The author has visited all the known asphalte fields of Western Colorado and North Eastern Utah. The observations he has made bear upon the origin of Dain Inconstructions ne has made occur upon the origin or petroleum, asphalte, natural gas, and other subterranean hydrocarbons, but the faces are hardly sufficient to lead to definite conclusions.—Photographic invistigation of prominences and their spectra, by George E Hale. Account is given of the methods employed by the suther for the photography of invisible solar prominences. Special attention has been directed to the photography of the bright prominence lines running through H and K, with a slit tangential to the sun's limb Four reproductions of negatives showing prominences illustrate the paper -A gold bearing hot spring deposit, by Walter Harvey Weed A microscopical and cliemical examination of some spicimens of ore from the Mount Morgan Gold Mine, Queensland, demonstrate of the Mount Morgan Gold Mine, demonstrate of the Mount Morgan G strates that the mine is a deposit of a hot spring, the ore being a siliceous sinter impregnated with anriferous hiematite. This a success since impregnated with an interest factories that is the only hot spring depost that has been found to contain gold in commercially valuable quantities, and although the sinter deposits from the hot springs of Yellowstone Park resemble those from Mount Morgan, no trace of the precous metals has been found in them -Res ciation of Stegosaurus, by O. C. Marsh. The species restored is Stegmann stingularin, from the Upper Jarassic of Wyoming A plate, representing the reptile one thirtieth its natural size, accompanies the paper.

THE American Meteor-logical Journal for July contains the following articles:—Franklin's kite experiment, by A. McAdie After groups whose details repreding Franklin's experiments, After groups whose details repreding Pranklin's experiments, the Billac Hill Observatory, new Roston, U. S., the chief Advance being that a every skep the electronel potential of the atmosphere was measured by an electrometer. The kite was sent up to accept the service of water from the electrometer during electrical disturbance of water from the electrometer during electrical disturbance of water from the electrometer during electrical disturbance always foreign when a final fighting was about to occur — Cloud height and the state of the control of the con 6500 m, circo stiatus 9652 m, circus 10,135 m. The The Upsale observations show that the base of the cumulas, is well as the cirrus, uncrease in height and evening, but neither of these conditions and by to the observations at blue till. I got an experience of the condition of the condition of the condition found to be 133 miles and hour. A comparison between wind and cloud velocity shows that below 500 metres, the wind of the cloud to the condition of the condition of the condition of the cloud to the condition of the condition of the condition of the decreases again velocity increases up to 1000 metres, and then decreases again velocity increases up to 1000 metres, and when the probability due to the fact that the double between 700 and 1000 probability due to the fact that the double between 700 and 1000 The Upsala observations show that the base of the cumulus, as probably due to the fact that the clouds between 700 and 1000 metres were movely observed during the morning, when the said 1700 metres were movely observed during the addition, when the cumulants moves allowest. Meteroological kills flying, by W. A. Eddy This is an account of some experiments made of which the contraction of the contraction of warm and current by means of Self-recording thermometers carried by a kill extract. Experiments showed that an altitude of 1800 feet contract the contraction of the offset contraction that many of 1800 feet could be obtained by using one kite, and that many hundied feet could be added to the altitude by hing the weight of slack string by fastening on larger kites. It is estimated that by this means an altitude of 4000 feet was obtained. The minimum temperature at an altitude of about 1500 feet, on February 14 last, was only 2' lower than at the surface

THURSDAY, SEPTEMBER 10, 1801.

AN EVOLUTIONARY CASTIGATION.

Science or Romance? By the Rev John Gerard, S.J.
(London, Catholic Truth Society, 1891)

HAT the doctrine of evolution should not be as sweet savour in the nostrils of the writer of this little book is in no way surprising, but that he should attack evolutionists and their ways with the weapons of flippancy and ridicule is an encouraging indication that the said doctrine has penetrated into quarters from which the author evidently thinks it high time to eject this modern heresy Having seized the scourge, Father Gerard accordingly proceeds to lay out all round, delivering his blows with vigour, if not with discrimination. and occasionally throwing such force into his strokes that the lash recoils and strikes the striker. In happy unconsciousness that he hits himself quite as often as he does his adversaries, the author goes on with his flagellation through six essays occupying 136 pages of somewhat close print. Although, as we have said, the attitude taken by the author will cause no astonishment, it is very much to be regretted that he has so far put himself out of harmony with the spirit of modern biological thought as to confuse the opinions, speculations, and working hypotheses of individual exponents of evolution with the broad principles of that doctrine For, however distasteful it may be to hather Gerard, it is an indisputable fact that the acceptance of that doctrine is well-nigh universal. and the question whether evolution is or is not a modus operands in nature, has passed beyond the phase of discussion among scientific thinkers and workers. So far as the author's attacks are directed against evolution as a principle, his weapon is as a bladder of air against the hide of a hippopotamus. It is satisfactory to find, however, that amidst the whizzing of his flagellum the author discerns the still small voice of reason :--

"The one fact given us, is the existence of evidence to show that various species of plants and animals have probably, or possibly, been developed one from another This, so far as it goes, is matter for scientific treatment, and the theory of evolution, within the limits thus afforded, has a right to be called a scientific hypothesis."

We are grateful for small mercies, and it would be ungracious to inquire too closely into the origin of this concession, but to those who read between the lines it will be apparent that the thirty years' campaign carried on by evolutionists has not been without result, even in the most unpromising fields.

The antagonst whom evolutionasts in general and Darwinnas in particular have found in the author of the work under consideration is a foeman not altogether unverthy of their steel. He brings into the arena a certain amount of knowledge of living things which indicates that he is an observer of nature in the field Moreover, he shows some understanding of his subject, and does not fall into the error of substituting blundering misconceptions for the statements of fact or theory which he is combating. Added to this there is a certain keenness of satire running through his essays which adds to their piquancy. The name of Father Gerard on the title-page

is a sufficient indication that evolutionists will find death and no quarter in his pages, and the reader will not be disappointed if he turns to these essays with the special object of finding the weaknesses of the modern school object of finding the weaknesses of the modern school expoged. But while the purely destructive attacks of the reverend critic may give satisfaction to those who helong to his school, the impartial reader will derive only amusement, and the man of science will soon perceive that the weapons of attack are not the legitimate implements of executific warfare, but the trucks of disputation concealed under a somewhat allump literary cloak, embellished here and there with a few flowers of the author's own culling

Having arrived at this general estimate of the work, it will not be necessary to do more than take a passing glance at its contents. The first csay, entitled "A Fangled Tale," opens with an attack ou natural selection, the author will have none of it, he objects to the term and he denies its efficiency.

"It would, in fact, be vastly more likely that we should cast aces three hundred times running, with a pair of unloaded dice, or tows 'fails' two thousand times with an honest coin, than that a development should be handed down by natural selection through ten generations, even if we start with so favourable a supposition as that one-half of the offspring tend to vary in the required direction."

This conclusion is based on a calculation in which the whole principle of selection is ignored?

The central idea of this essay is, that evolutionists have reduced the operations of Nature to "chance," "accident," and so forth We are told, at the very outset —

"The cardinal point of the doctrine they proclaim is, that no purpose operates in Nature, and that the explanation of everything we see is to be found in the mechanical forces of matter"

In order that there may be no misunderstanding as to what the author means by chance, he defines it as " the coincidence of independent phenomena-that is, of phenomena not co-ordinated to an end." By what criterion. may we ask, are "chance" phenomena, as thus defined, to be distinguished from "pre determined" phenomena? Prof Huxley's example, quoted from Darwin's "Life and Letters." is critically dealt with, and the author tells us that this is "utterly wide of the mark. The phenomena here described [a storm at sea] end with themselves, they lead to nothing else; nothing follows from them They are mere effects, and not, so far as we know, a means to obtain a result beyond" The insight which the author appears to have gained into the motive, or want of motive, in nature is really most enviable; the man of science who must perforce arrive at his conclusions by the circustous roads of observation and experiment can only look with admiring wonder upon a method which is so completely foreign to his philosophy.

This same dummy, chance, is well belaboured throughout; among the slam, after this first lit, we find not only Prof Husley, but Andrew Wilson, Oscar Schmidt, and, above all, Mr. Grant Allen, whose form is so terribly hacked that he appears to have been in the very centre of the fray, if not the chief object of attack

Tilt the second is headed "Missing Links," and the onslaught begins upon Mr. Wallace, whose work on

"Darwinism" appears to have been published in the interval between the first and second essays And here -perhaps not altogether disconnected with the appearance of Mr. Wallace's book-we find that the author has executed a series of mental evolutions with such skill that we have to rub our eyes in order to make sure that we have not deceived ourselves as to the position which he has actually taken. For natural selection, which, in the first essay, was considered to be so feeble as to be incapable of carrying on development through ten generations, even with the most favourable assumptions to start with, is now considered to be "as yet but hypothesis. and hypothesis which needs confirmation from fuller inquiry into the facts of the case, just as much as the other hypothesis of the continuity of forms between one species and another" At any rate, we seem to be justified in concluding from this that, as a scientific hypothesis, natural selection ranks with evolution, which, we were told in the first essay, had a right to be so called The change of front has been very skilfully made, but that there has been a change is evident from the foregoing extracts

The way in which evidence, which has been hitherto considered as fairly good from the evolutionist's point of view, can be manipulated so as to bear the quite opposite interpretation, is a study in intellectual jugglery which might be worthy of serious attention by certain classes of politicians. The second essay furnishes several examples of such feats More especially may attention be called to the remarkable way in which the palæontological evidence is thus disposed of, and still more remarkable is the author's Podsnappian dismissal of the embryological evidence. Wallace's later treatment of natural variation is accepted .-

"The variations of form and structure which occur among wild animals—and the same is to be said for plants—are not occasional and minute, but incessant and important. There is clearly an end of the objection based on the supposed infinitesimal character of

But if the reader fondly imagines that this admission brings the author any nearer to Darwinism he will be grievously mistaken For in this larger and more widely divergent variability Father Gerard sees a "centrifugal tendency" by which "every varying climate and soil and circumstance on the face of the globe should make its own species, or rather there should be no species at all, but a fleeting and evanescent succession of individual forms, like the shapes of clouds in a windy sky" Of course, evidence has to be adduced in disproof of this astonishing result, to which the later study of variability has led us, or rather should have led us But there is no difficulty at all about this the house sparrow and the water-crowfoot, we are told, are widely distributed over the face of the globe, and yet retain their specific forms and characters True, but the instances of cosmopolitan species retaining their distinctness are few and exceptional: we are not told anything about local forms and races, or about "representative species", we hear nothing about widely distributed species which merge imperceptibly into each other to the utter confusion of those who make species their particular study Can it be that these facts

author discovered some absolute criterion of species? If the latter is the case, he can hardly be congratulated on his definition -

"It would seem to be simpler and planer to say that a species is a permanent group [italics mine] of plants or animals framed in all particulars after a single type."

Enough has been said about this work to indicate its general tendency its tone, on the whole, is antagonistic to evolution, but with respect to the special Darwinian form of this theory antagonism but feebly expresses the author's attitude In each essay, the attack generally centres upon one or two representative writers; eg. the third essay (" The Game of Speculation") dealing with Mr Wallace, the fourth ("The Empire of Man") with Prof Huxley, the fifth ("The New Genesis") with Messrs Grant Allen and Edward Clodd, and the sixth (" The Voices of Babel") with a number of miscellaneous authorities, such as Mr Herbert Spencer, Mr. Frederic Harrison, the late Prof W. K Clifford, and Sir James Stephen, of whom the author makes horrid examples by the very simple expedient of pitting their opinions against each other. From this general view, it will be seen that, so far as science is concerned, the effect of Father Gerard's last production will be practically m/ Among certain classes of general readers it may be mischievous, but we do not imagine that the mischief will spread very far. As the criticisms are for the most part destructive, it is impossible to attempt to deal with them in detail in these columns Where it is possible to glean a vestige of a constructive idea, it will be seen that the main point towards which the author appears to be driving is that the doctrine of evolution-especially in its Darwinian form-is destructive of the notion of preconceived and determinate "plan." eg. .--

"Intrinsic forces working definitely towards one play not indeterminate forces swept hither and thither by external agencies like a cloud of dust, are suggested by the phenomena of nature"

We have become so accustomed to this style of criticism from all kinds of anti-evolutionary writers that it is almost superfluous to attempt to deal with it again But it may really be asked whether those who are so constantly dinning this idea of a "plan" in nature will now condescend to give us some idea what that plan is. If "intrinsic forces are working definitely towards one plan," surely the author to whom has been permitted this glimpse into the inner sanctuary might enlighten the outer darkness a little by telling us something about the general scheme, or, at any rate, by giving us a notion as to the method by which he has arrived at such an important conclusion On the other hand, if the author is satisfied that there is such a pre-arranged plan-whether he reveals that plan to the uninitiated or not-I, for one, fail to see how evolution. Darwinian or otherwise, has anything to do with the matter. If Father Gerard has managed to extract from the writings of popular authors, this notion of antagonism between ideas which are not necessarily antagonistic, with these authors must rest the responsibility. It cannot be said that the castigation which he has inflicted is altogether unmerited; there has been a great deal of crude and hasty speculation perpeare inconvenient and "not to be endured"? or has the trated in the name of evolution, and the blows aimed do occasionally tell in the right direction. Had Father Gerard not sacrificed his position by aiming so much at smart writing—had he favoured us with more solid thought instead of endeavouring "to split the ears of the groundings"—his lucubrations would have received more respectful attention. But satire and cynicism, interspersed with ridicule, are not the best methods for securing consideration from men of science, and it is surprising that the author should have resorted so largely to their use. R. MENDIA.

THE LAWS OF FORCE AND MOTION

The Laws of Force and Motion. By John Harris (Kuklos). (London Wertheimer, Lea, and Co, 1890)

In his preface the author, very rightly, sounds a warning note against the arrogance of Conventional Science, in its tendency to become ultra-conservative, intolerant, and extremely dormatic

But Real Science will always welcome and encourage attack and contradiction, feeling sure that Truth will ultimately pread in the consensus of the majority who have devoted themselves dispassionately to the consideration of the facts in dispute. 'Transibunt multi et augebit Scientia'"

We presume the author would not ask to be judged with more leniency than he has displayed for the opponents he has singled out, so we may say at once that, after careful winnowing, we have not secured those grains of fact and truth which we were led to expect

The experimental apparatus described seems carefully constructed and suitable for exact measurements, but does not differ essentially from that employed by Smeaton more than 100 years ago. However, the author assumes the true scientific sceptical spirit, in refusing to accept implicitly the statement of theoretical laws without putting them to the text of markitale accurate many fraction.

Mathematicians will understand the nature of the author's attacks on Conventional Science from the specimen on p 31.—

"It would seem that, some time ago, a highly influental party of natural philosophers (Lehnix, the two Bernoulis, &c) entertained and supported the idea that the momentum of a moving body varies as the square of the velocity. This idea or conclusion was probably based on an inference, that, since a double velocity of the resistance required four times the force to produce is, four times the momentum must have been imparted to the resistance."

After this wavering as to the meaning of momentum, we are quite prepared to find (p 60) that the author is of the school who declare that the moon does not rotate.

The author cannot decide between 16'1 or 32'2 for the value of g (p 24); and cannot settle in consequence whether the normal acceleration in a circle is the squared velocity divided by the radius or by the diameter (p. 19).

"Tangential force" is, in the author's opinion, a more correct scientific term to use than "centrifigal force," although he allows that the latter is ballowed by long usage; but in his treatment he enunciates a theorem p.21, "The actual lineal ratio of the sine to the arc, when the arc is an octant; is 9 to 10," quoded from his own "Treatise on the Circle and Straight Lines"; this makes

 $\pi = 2 \sqrt{2 + 0.9}$, a result worth recording by collectors of mathematical curiosities.

We hoped to find something combative in the articles on the Tidal Effect of Lunar Gravitation (p 57), and on the Moon's Gravitative Influence at the Equatorial Surface of the Earth measured by Pendulum Oscillations (p 76), considering that even the great Abel wint astray in his theory at this point; but our author confines himself to vague generalities.

He would perform a valuable service to Science if he employed his experimental skill in observing the effect of Lunar Gravity on the Seconds Pendulum, as Conventional Science asserts that this effect does not amount to more than a rate of one zooth of a second in the day, although so noticeable in the Tides

"Some Propositions in Geometry," by the sanie author, is advertised at the end of the book, whereof the Trisection of the Angle, the Duplication of the Cube, and the Quadrature and Rectification of the Circle, occupy the chief part, but we wonder whether the author has quite settled in his Geometry that the versed sine (or vertral height) is proportional to the chord, in a circle (p. 71). This might have been a misprint, but that the author adds immediately a numerical illustration, by saying that, if the chord is duplicated, the versed sine is also duplicated.

And this homely mode of verifying a law of comparison, by halving or doubling some quantity, and then observing the consequent change in the phenomena; is the single idea we consider worth lifting from the book, for general purposes of convincing argument and illustration of a mathematical law A G G

OUR BOOK SHELF.

An Introduction to the Mathematical Theory of Electriuty and Magnetism. By W T A Emtage, M.A. (Oxford Clarendon Press, 1891)

THE want of a text-book especially designed for the use of candidates for examinations in which a knowledge of the more elementary portions of the mathema-tical theory of electricity and magnetism is demanded has been felt for some time. Though the absence of such a book has caused some inconvenience, we are not at all sure that it has been detrimental to the study of electricity, for hitherto the candidate for a mathematical examination in electricity has been compelled to learn the subject from books such as those of Maxwell, or of Mascart and Joubert, in which electricity is treated as what it really is outside the evamination-room-a subject in which mathematics and experiment are closely mixed and mutually helpful. it is to this that, we think, is to be ascribed a good deal of that interest which electricity, above all other subjects, seems to excite in its students. When, however, the analytical parts of the subject are divorced from the experimental, we do not believe they will be found to excite any special enthusiasm, or that the result will be much more interesting than an ordinary text-book for the Mathematical Tripos on, say, hydrostatics

There is no doubt, however, that there is a demand for a text-book suitable for examination purposes, and this demand will, we think, be well met by the book before us. The scope of the work may be described by saying that it includes nearly all the analytical parts of Maxwell's larger treative which do not involve analysis higher than the simpler parts of the differential and integral calculus;

it thus covers the portions of electricity and magnetism which, under the new regulations, are selected for examination in Part I of the Mathematical Tripos, and we have no doubt it will be found useful for that examinations are generally clear and concise. Among const minor, onto the control of the contr

Le Sommeil et le Système Nerveux Physiologie de la Veille et du Sommeil. Par S Serguéyeff (Paris: Felix Alcan. 1800)

It is difficult to understand why a writer upon the higher branches or outlying districts of neurology should assume that his readers are totally ignorant of the radiments of that science, and should occupy nine-tenths of his book with a description of the anatomy and physiology of the nervous system—If, indeed, for the purpose of throwing new light upon his subject, he presented his facts in a new form, or taught them from a novel point of view, or arranged them so as to bring out some new principle, then arranged them so as to bring out some new principles, time-there might be an excuse for restating the facts , but even them a brief summary would be enough for the pur-pose, there would be no need for the rediscussion of settled theories and the requestation of trite authorities Scarciely ever do we find a writer on neurology who is content to assume that his readers are acquainted with the alphabet of his subject, or who will refrain from inflicting upon them the wearisome account of cells and fibres, of corona and cortex, illustrated by the familiar engravings that have done duty in so many previous books. The vicious habit is common enough and bad enough, but very rarely is it carried to such an extent as in the book before us, in which only about three hundred out of the seventeen hundred pages of which it is composed are devoted to the subject of which it is said to treat, the great bulk of the subject to which it is said to freat, the great blik of the book being occupied by anatomical and physiological descriptions which are not in this case even relieved by illustration. So far is this system of padding carried, that the author has even inserted, in his book on waking and sleeping, descriptions of the minute structure of the retina, of the internal ear and the organ of Corti When we have at last waded through his pages of preliminary matter, we do not find that he presents any fresh theory of sleep that is worth considering, or that he has any new facts to bring under our notice It is a shanie that a student should be trapped by an enticing title into spending his time in reading such stuff

Elementary Science Lessons By W. Hewitt, B.Sc (London: Longmans, Green, and Co, 1891)

THE thirty-six object-lessons contained in the present volume form the third part of a scheme of lessons drawn up by the author at the request of the Liverpool School Board. They are designed for children of Standard III, and are in continuation of others given in previously pub-

NO. 1141, VOL. 44]

lished volumes suitable for Standards 1 and 11. The author's long experience in teaching science to children in elementary schools gives him the ability which is mecessary properly to draw up such a course as the one before us. For the most part the facts and principles dealt with relate to the classification of bodies into solids, the same of the solid principles of a paratus, and the inferences to be drawn from them must be manifest to all children for whom the work is intended. Whenever possible, the principles considered in the lessons are applied to explain physiographical phenomena, thus ading the development of that imtelligent observation which is the generally good, and elementary school teachers will find in the work exactly what they require for their pupils

Solutions of the Examples in Charles Smith's "Elementary Algebra" By A. G. Cracknell (London Macmillan and Co., 1891.)

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Niether can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communication:

The Anatomy of Heloderma,

This number of Nevuus for July 30, which I have only just seen, contenting 10, agoly a criticism of a sistement of mane, to which I have to asswer It is stated in my paper on the oncology of Holderma that there are eight or mine premarable years of the property of the p

A Straight Hand.

ALTHOUGH my writing master, who was an Englishman, taught me stanting letters which old habit still clarge to, I approve highly what you as a geainst it (NATURE, August 6, p 335). Allow me to add some remarks on another side of that question. For many years past I have had in succession several amanucases, and my first care has always been to require a straight hand without any clittantollo between up and down

sirokes These precepts and a few minor ones have been easily followed in all cases. I inclose a few lines copied from your interesting journal by a youth who does not understand English he would have done this work with more care had he known that I wanted merely a sample At all events it is most easy

Straight letters without hair lines give the reader a comfortable Straight letters without hair lines give the reader a combrabile callify which is a far greater compliance to a correspondent than facility which is a far greater compliance to a correspondent than last fifty years. We suppose that alant writing has been invented on your side of the Channel, and we call it therefore circlive any fairs. However, experience seems to show that it is more easily deformed than a straight one, and that it degenerates more easily detormed than a straight one, and that it degenerates often into an inlegible scrawl, cassing much loss of time, or even, often into an inlegible scrawl, cassing much loss of time, or even, are told that the schoolmatter is abroad, but I am afraid that he leads our children on a files trail far away from the man aim of writing, which is legislaty. Is the invention of type writers the antidote or the outcome of illegible slanes? Some of your philosophers may answer this question while giving a wholesome lesson to the schoolmaster.

A D'ABBADIE (de l'Institut)

Abbailia, Hendaye, France, August 16.

Cordylophora lacustris.

IN NATURE for June 4 (p. 106) Mr. John Bidgood recorded IN NATURE (of) june 4 (p. 105) Mr. John Biagooti recorded the pre-ence of this Ilydrozon in wast musibers on «shimerged roots and stems in the Ant, Bure, and Thurne — Islt then its only known Norfolis locality was that given in Allman—"in a agricultural drain near Lyan Reght." This summer innumerable coloniem were to be seen on weed floating on the surface on both sides of the Thurne from Ludhain Birdge right up to Hicking Broad. A boatman told me he had ween. "then isnesses" every Broad A boatman told me he had seen "then insees" every sammer for many years past Mr Edward Corder, the Secretary of the Norwich Natural Flutory Society, took some early in June, and some, which he was good enough to send me, is still living in a 4 ounce bottle All the authorities tate that Cordylophora is a "light shunning animal," and the localitieshitlicrto recorded certainly warranted such a conclusion. But the colonies taken from the surface of the water by Mi. Corder, and coionics taxen from the surface of the water by Mi. Corfier, and those. I took some time later, were stronger and cleaner than those obtained from below the surface. I distributed some of the gathering which I brought back to London, and learn that it is all doing well in ordinary aquarta. Some that I sent to Mr Bollon for distribution unfortunitely died in transit. One to Mr. Botton for distribution under the stem of a Potamo geton, was kept in the shade for a fortinght, the tubes became faced, and the hydranth pendent, but they revived within twenty-four hours when exposed on the ledge of a window with a western sapect. This seems to point to a change of habit All the colonies were doubtless founded below the surface of the water, and the weeds, when cut to clear the fairway for wherries, were floated up lowards Hickling Broad by the tide But if reproduction takes place—as it certainly does—under these conditions, is it not probable that we shall have a race tolerant of direct light, if not as sensitive thereto as Hydra HENRY SCHERREN.

Absolute and Gravitation Systems

Absolute and Gravitation Systems
Tita present condition of things is such that students of engineering need familiarity with, and shishy to use, both systems of measuring force and related quantities. It seems necessary, so that the state of the state

There is, in my opinion, much that is undesirable about this method of statement; the new mass-unit appears quite artificially in this one only of the many uses of the conception of mass, for the purpose, I suppose, of making it possible to put in

generally applicable form such statements as "Force is measured by change per second in momentum" My particular objections to it, however is that it locates the point of divergence of divergence of divergence of the control of the that the force unit is the first cardinal point of difference, and that the absolute system simplifies here, while the gravitation system adopts another convention, which may be called arbitrary as opposed to the simpler one fixed upon by its rival.

In the hope of hastening the day of agreement in presenting the connection of ideas which underlie so much of modern physics and its applications, I have thought it permissible to state in summary, and for British units, the scheme used in my own teaching of mechanics. The claim is not advanced that the numerical work becomes different, indeed, the appended table is equally valid whichever basis be chosen, but there does seem to be a gain in logical clearness, as well as in what we

may call historical accuracy

Absolute System — Fundamental units foot, pound, second
Units of force, work, impulse derived in the usual way, so as to

make proportional factors unity make proportional factors unity

Gravilation System — Fundamental units as hefore Unit of force, the weight of one pound under circumstances specified to the required degree for scientific definiteness (locality, vicuum)

the required degree for scientific definiteness (locality, vecuum) Units of work and impulse connected with the force unit, so as the control of the scientific of the standard of the control of the standard currents are glance y, is the value of for the standard currents areas, and is to be regarded an other or in each case affecting the product of the other factors. The other symbols explain themselves

$$\begin{aligned} & I h w h w \\ & P - m h, \\ & (work) \int P J h = (change in) \frac{m v^2}{2}, \\ & (impulse) \int P J H = (change in) m v \\ & Grat that to v \\ & P = \frac{m f_1}{2}, \\ & (work) \int P J G = (change in) \frac{m v^2}{2}, \\ & (umpulse) \int P J H = (change in) \frac{m v^2}{2}, \end{aligned}$$

$$(umpulse) \int P J H = (change in) \frac{m v^2}{2}, \\ & (umpulse) \int P J H = (change in) \frac{m v^2}{2}. \end{aligned}$$

I be choice of force unit here affects what is logically subsequent to it, as it must, but leaves inaffected what is logically

quent to it, as it must, but leaves intartected what is logically netcoclent, as it ought.

So small a change as that of regarding g₁ as a divisor of m alone changes the basis of pre-entation, but there is an important difference of thought involved.

Eucalyptus as a Disinfectant

In a paragraph on the use of Eucalyptus branches for disin-fection, as recommended by Baron von Mueller, you have un-intentionally stated that to be the manner in which I have used **Facalyptus**

Facelyptus

For the last two years I have used "Tucker's Eucalyptus Disinfectant" (a solution of antiseptics in the essential oil) in all
cases of scarlet fever and diphtheria, and have not had one case
of infection. In the former disease I have not used any nolation, and in most cases have not excluded the other children of tion, ann in most cases have not excluded the other children of the family from the sick room. None of the cases, except two or three that were severe, were kept to their bed-room more than ten days; the solution of as or eight weeks being unnecessary, as the cutted is perfectly disinfected. This is accomplished by rubbing the disinfection to ver the whole body twice and their once a day for ten days.

Baron von Mueller, in a letter I received from him, quite approves of my method of disinfecting by inunction. I read a

paper before the Epidemiological Society has year on the subject. It is published in the Society's Transactions, and in a separate form by Mr. Lewis, of Gower Street I also read a paper before the International Congress of Hygiene on antiseptic insuction I mis I have related the experience of other medical men in confirmation of my own. One, whose child had scarlet fever, placed his two other children in the same room, and kept them there for eight days, and they did not take the disease. This will be published in the Transactions of the Congress, and any one interested in the disinfection of infectious diseases, may obtain all the information they require from those two papers.

I Brandon Curgenvan.

Teddington Hall, S. W., August 17

Alum Solution

ONE frequently reads, in accounts of experiments on the physical or chemical action of lemmons rays, that a solution of instancial reads of the control action of lemmons rays, that a solution of lemmons rays, that a solution of the solution of the reservoir action of the solution of the reservoir action of the solution that, because alam stelf cuts off a garge proportion of heat rays than any other easily available control of the solution of solid, its solution should be more effective than any other liquid sould, he solution among the more energies that hay write singular. The only figures bearing on the question with which I am acquainted are those of Mellom, and he, as cited by Ganot, states the percentage of heat rays transmitted by alum solution states the percentage of near rays as 11. Why, then, not as 12, and that by distilled water as 11. Why, then, not a HARRY NAPIER DRAFER. Why, then, not use Dublin, August 27

A NEW KEYED MUSICAL INSTRUMENT FOR TUST INTONATION

ONE of those subjects which periodically turn up for discussion, and then vanish for an interval of neglect, is the possibility of obtaining just intonation in the performance of music. I hose who have studied theory, properly so-called, know very well that the series of musical sounds commonly used, as expressed on the planoforte, do not give the true harmonic combinations on which the art is based, and many zealous attempts have been made to cure the evil One of these, showing some novelty and much merit, is now exciting the attention of eminent musicians on the Continent, it was men-tioned briefly in NATURE of April 2 last (p 521), and it may be interesting to many readers to give some further account of its general features We may, however, preface this with a few words on the state of the question generally.

Although the equal division of the octave has now taken such a firm hold on modern musicians, it is only within a comparatively recent period that its use has become common It was well known at an early date, but its defects checked its use until the general introduc-tion of the class of instruments which have culminated in the pianoforte; the reason of its adoption then being that the want of sustaining power in the clavecin and the harpsichord so diminished the discordant effect as to make the faulty tuning endurable People then began to get accustomed to it, and it was soon found that the system gave such extraordinary facilities for chromatic music, that the cultivation of this style became enormously developed. Hence the chromatic style and the equal temperament have become closely allied, and it is almost a matter of doctrine that the pianoforte division of the octave is a necessary element for the proper performance, or proper understanding, of the compositions of modern days.

For organs, the application of the equal temperament came much later Down to about the middle of this century they were tuned on a system which gave the most usual keys fairly in tune, at the cost of an occasional harsh chord, which, for church purposes, was considered

but a small price to pay for the general smooth and har-monious effect. But when highly skilled players began to increase, they required the organ to be more used for exhibition, and for this purpose the introduction of the equal temperament was deemed desirable. And so, as it thus commanded the two most powerful sources of music, it crept into use also by stringed instruments, orchestras, and voices, and so it has become general.

The consequence is that, now, practical musicians are in the habit of accepting the equal-tempered intonation as genuine and true music, and as the study of the prin-ciples of musical structure is by no means highly en-couraged in this country, efforts are seldom made to undeceive them. Students are authoritatively told that questions about just intonation may be interesting to physicists and mathematicians as recondite problems in acoustical science, but that they have no bearing on "practical" music, and that, therefore, musicians need practical music, and that, therefore, musicians need not trouble themselves about them. Some years ago, at a meeting of one of our musical educational establishments, it was said, "We do not here make music an affair of vibrations"—a sentiment which was received with loud applause

No doubt some enthusiasts have carried the investigations on this subject to a degree of refinement which far outruns practical utility, and one can have little sympathy with those who delight in reviling and despising the duo-decimal scale, seeing that it has been the means of materially advancing the art, and that the modern enhar-inouic system, founded upon it, has been so thoroughly incorporated into modern music that it is difficult to see how it could be now ignored

But, on the other hand, one must, if one is to exercise reason and common-sense in musical matters, be equally reason and common-sense in musical matters, we equally at variance with the party who, arrogating to themselves the title of "practical" musicans, force on us the equal temperament to an extent which really means the extinction of true intonation altogether. We now, indeed, never hear it, and in fact only know by imagination what a true "common chord" means.

The principal objection to this state of things is that he ears of musicians become permanently vitiated, and lose the sense of accurate intonation, or the desire to approach it, which is tantamount to abandoning the most precious feature that modern music possessesnamely, beauty of harmony. A chord of well selected sounds, exactly in tune, is a very charming thing, but it is a thing unknown to ears of the present day 1 can recollect the time when singers and violin-players strove recollect title time when singers and violin-piayers surve to sing and playin good tune, and the effect of such un-accompanied part-singing, and such violin-playing, was very delightful. But now, music not being made "an affair of vibrations," one is often ashamed of the quality of what one hears; nobody seems to think purity of harmony, either with voices or violins or orchestras, to be a matter worth striving after

It is surely a reasonable wish that this should be checked, but one must be reasonable in one's expecta-The pianoforte must certainly be let alone, and so must the organ when used for exhibitional purposes, though its cacophony under the present tuning detracts much from the pleasure of hearing such fine playing as is now common. But vocalists and violin-players ought to be encouraged, as of old, to sing and play in tune, and for this purpose what is wanted is an instrument which will keep up and circulate the tradition of what true music means. To attain this, therefore-te to construct an instrument which shall enable a player, with moderate ease, to play polyphonic music, of moderately chromatic character, in strict tune—has been the aim of many ingenious musicians and mechanics.

I need not go into history. Everybody may see at South Kensington the wonderful enharmonic organ, built half a century ago by General Thompson, and may read of the instruments described by Helmholtz, and his voluminous commentator, the late Dr Ellis: and the efforts in the same direction of Mr. Colin Brown, and of Mr Bosanguet. who has devoted much attention to the matter, are worthy of all praise But my object now is to describe but my object now is to destroe the latest attempt of the kind, by a native of Japan, Dr. Shohé Tanaka Persons who have lately had to do with that country have been well aware, not only of the natural ingenuity of the Japanese, but of the high standing which many of their youth have taken in scientific studies. Dr Tanaka combines these two qualifications After an industrious preliminary education in his own country, he went to Berlin, where he has been for five years studying physical and mechanical science under the best professors, and with these he has combined also a study of music. He has published, in the Vierteljahrsschrift fur Musikwissenschaft for 1890, a long essav on the subject generally, which fully demonstrates his on the subject generally, which fully demonstrates his knowledge of it, and he appears to have made a very favourable impression in Germany. He exhibited his "Enharmonium," as it was called, to the Emperor and Empress, and he produces testimonials from many musicians of the highest rank, among whom are Joachim, Von Bulow, Reinecke, Richter, Fuchs, Moszkowski, the whole staff of the Leipzig Conservatoire of Music, and many others These not only speak highly of the instru-ment, but (in strong contrast to the English authorities) earnestly support and recommend the object it is proposed to serve Indeed, some of the testimonials are Von Bulow especially says -

"I have requested the maker to make me such an enharmonium for my personal use at home I am earnestly desirous to protect myself during the few remaining years of the exercise of my art against constantly possible relapses into already conquered errors. In order to make pure music it is necessary to think in pure tones It is default to make pure music it is necessary to think in pure tones It is default on which nearly all corruptions of hearing paniofortie let on which nearly all corruptions of hearing

may be traced "
With these credentials the inventor has brought a
sample of his instrument for examination in England,
and I may proceed to give some idea of what it is like.

The great object to be aimed at is facility of performance. It is in this respect that most of the former instruments have failed; the multitude of notes has generally required a new kind of claver, or the manner of manipulating them has been so complicated and difficult as to require a special learning attended with much rouble. The required a potential learning attended with much rouble. The Key-board modelled precisely on the usual pattern and use. But T. Tanaka has gready simplified the problem by adopting the transposing system, often adopted with pannofortes Whatever key the music is in it, it is played in the simplest of all keys, the key of C, and by means of a bodily shifting of the key-board to the right or left, it is set so at oact in the key required. It is, in faci, the principle used in the music in the key of C, and the transpostance of this to the key required is previously arranged as a part of the mechanism of the instrument; or, rather, as the author puts it, the music may be read and played on the tone sold-in system, and her might have adopted its symbols

if he had not feared it would be too startling a change. The points in which the new key-board differs from the ordinary one are, that the black keys are divided, some into two and some into three parts, and one additional shorter and narrower black key is introduced between the Z and F white keys. This arrangement gives twenty notes, which suffice for modulating into a reasonable number of keys with sharp signatures.

To provide for modulations into keys with flat signatures, since these and the sharp modulations are not NO. 1141, VOL. 44 both wanted at the same time, six of the notes can be instantaneously changed for the purpose, at any time, in a manner hereafter explained

The whole of the keys are well under the hand, and, if the performer knows which note he ought to use, he can take it in any usual chord without difficulty.

Fig 1 represents one octave of the key-board as arranged for the key of C, with provision for modulating into keys with sharps.

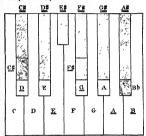

Fig. 1 -As arranged for modulation into keys with sharps

In order to explain the exact intonation or muscal position of the notes, the author adopts a notation already pretty well known—namely, when the letter indicating a note, has no line above or below it, it is intended to correspond with what may be called the "Pythagorean" fifth upwards from C. 4s a base. If the letter has a stoke below it—thus, E—it is a comma below that position, and if the stroke is above—thus, 5—it is a comma above that position. Two strokes below—thus, Cg—nultrait two commas below.

indicate two commans seew with the confinary seem white the many seem white the seem ordinary notes of the major scale of C, according to the intunation usually understood, et the major trads on the tonic, dominant, and subdominant, being perfectly in tune liut as, for certain harmonies, variations of some

liut as, for certain harmonies, variations of some of these notes are required, there are four alternative small white notes, D, E, G, and A, placed at the near extremity of four of the black ones. For example, the note D is the one required to make the true minor third

The position of the keys for the sharp notes, and also their intonations, will be seen in the figure F # and C # each require alternative values, a comma distant from each other, and these are obtained by dividing the black keys in the manner formerly practised with some organs in this country.

It will be seen that there are in all twenty effective finger keys, each sounding a separate note. When it is requisite to modulate into keys with flats,

When it is requisite to modulate into keys with flats, the above arrangement will not answer, and the necessary change is made by a lever placed conveniently for being worked by the knee of the player, like the swell of a harmonium. When this is pushed over, the six hindmost black keys are altered from sharps to flats, as shown in Fig 2. alternative F are added This change gives six new notes, so that the total number of sounds used in the octave, for the key of C with its modulations, is twenty-six

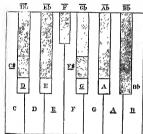

Fig. s -As altered for modulation into keys with their

As a further indication of the exact musical positions of these twenty-six notes, their ratios of vibration with the keynote C, may also be given And the logarithms of these (here limited, for simplicity, to three places) will represent approximately the height of each note above C In this scale, an octave is represented by 301, a mean semitone by 25, and a comma by 5

Table of the Positions of the various Notes used for the Key of C

C = I	Logaruhm O	Ratio	Logarith
$D = \frac{9}{8}$	51	$D = \frac{10}{9}$	46
$E = \frac{5}{4}$	97	$E = \frac{81}{64}$	102
$1 = \frac{4}{3}$	125	F = 27	130
G = 3/2	. 176	$r = \frac{40}{27}$	171
A ≈ 5	222	$A = \frac{27}{16}$	227
$B = {15 \over 8}$	273		
F# - 45	148	$F_{2}^{\#} = \frac{25}{18}$	143
$C_{\frac{1}{2}}^{\frac{1}{2}} = \frac{1}{128}$		$C_{3}^{*} = \frac{25}{24}$	18
$G_{1}^{\#} = {}^{25}_{16}$. 194		
$D_{8}^{\#} = \frac{75}{64}$. 69		
$A_{\parallel}^{\#} = \frac{225}{128}$	245		
$E_{4}^{\pm} = \frac{675}{512}$	120		
NO. 1141	, VOL. 44]		

Bb = 9 5	Logaruhu. 255	Ratio Bb = 16	Logarithm 250
$Eb = \frac{6}{5}$	79		
$Ab = \frac{8}{5}$	204		
$\bar{Db} = \frac{16}{15}$	28		
$Gb = \frac{64}{45}$	153		

This information will enable any student of musical theory to judge of the capability of the instrument to play modern music with just intonation. The great object is, of course, to play the consonant triads, major and minor, in strict time, and it will be found that the instrument, as above arranged, will play the following

> Major Triads on -C, D, E, F, G, A, B, F#, Bb, Eb, Ab, 105, Gb, Minor Friads on-

C, D, E, F, G, A, B, F#, C#, G#, D#, A#, Bb,

and some of each in displicate with a comma variation These would certainly seem sufficient for all ordinary

These would certainly seem suincient to an ordinary music in C major or A minor.

By means of the transposing movement, the key-board can be set upon either of the eleven other keys, for which a similar modulating power is obtained, except in some very remote cases In order, however, to effect this, ten additional notes are used, making thirty-six in all But the adaptation of them is entirely automatic, and the mechanism for this purpose constitutes one of the chief novelties of the invention

This is the provision for the purpose by the manu-

This is the provision for the purpose by the manufacturer Now, let us see what the performer has to do. In the first place, whatever key the original compositions in, it must be played in the key of C. In these days of strict examinations by the College of Organists, it is not uncommon to find players who can transpose at part of the property of th is nothing in comparison with the great gain in simplicity of the key-board

Secondly, the performer has not only to play the music in the ordinary way, but he has another problem before him-namely, where certain notes are in duplicate, he has to decide which of the two to use Now this, although by no means a difficult matter, requires some knowledge of the theory of music, in a sense beyond what is ordi-narily taught To explain it would lead us into more technical detail than would be proper here, but Dr Tanaka, in compassion for those unfortunates with whom music "has not been made an affair of vibrations," has shown that the printed music can have certain very simple symbols prefixed to the notes, which will easily guide the purely "practical" player what to do

In this way any competent organist, though he may never have heard of the system before, may, after a few minutes' explanation, and a quarter of an hour's practice, play any piece of music correctly in the true musical intonation, a result which, I believe, has never been attained by any former instrument, and which says much for the ingenuity of the whole contrivance
It is recorded that the Emperor of Germany expressed

a wish to see the experiment tried on a large organ, and a wish to see the experiment tried on a targe organ, and the inventor is now engaged in constructing one with eight stops, and a simplified enharmonic pedal-clavier, for the Prussian Government.

WILLIAM POLE.

THE NEW AUSTRALIAN MARSUPIAL MOLE—

O UR Corresponding Member, Prof. E. C. Stirling, of the University of Adelaide, has most kindly sent to us an original water-coloured drawing of the newly-discovered Australian Marsingh, prepared from a pencil sketch taken from life. The animal is represented upon the surface of one of the red animal is represented upon the surface of one of the red animal is represented via Arnolda Instruction, the "portugung grass" of the interior of Australia, and is figured of the natural size. The drawing will be exhibited at the first scientific meeting of this Society in November next, but in the meanwhile can be inspected in our library by any naturalist who may

Prof Surling has also sent us a copy of his paper in the Transactions of the Royal Society of South Australia (read February 3 of the present year), in which this extraordinary animal is fully described. The subjoined particulars as to its habits, extracted from Dr Surling's article, will be interesting to the readers of Nature.

"It appears that the first specimen was captured by Mr Wm Coulihard, manager of the Frew River Station and other northern runs belonging to the Willowie Pastoral Company Attracted by some peculiar tracks, on reaching his camp one evening on the linke River, while traversing the Idracoura Station with cattle, he followed them up, and found the animal lying under a tussock of spinifes or porcupine grass (Triodia pritans) Though and powers of observation usually acquired by those who live lives of difficulty and danger, this was the first and only specimen of the animal he ever saw As previously stated, this found its way to the Miseum through the agency of Messrs Benham and Molineux. The three subsequently received shortly afterwards, as well as the last lot recently secured by Mr Bishop during our journey through the country, were also found on the Idracoura Station This is a large cattle-run comprising Idracoura Station Ins is a large cattler-un comprising several hundred square miles of country in the southern part of the Northern Ferritory of South Australia, which hes immediately to the west of the telegraph line between the Charlotte Waters and Alice Springs Stations. The great dry water-course of the Finke River, which runs from north-west to south-east, bounds the run for some eighty miles on the north and north-east. Its distance from Adelaide is, roughly speaking, a thousand miles Flats and sandhills of red sand, more or less well covered with spinifex and acacias constitute a large portion of the country, and the rainfall is inconsiderable. Curiously enough, all the specimens of Notorycles hitherto received by me have been found within a circumscribed area, four miles from the Idracoura Head Station, which is situated on the Finke watercourse itself, and almost invariably amongst the sandhills I have it, however, on very fair authority, that the animal has been seen on the Undoolya Station, which lies immediately south of the McDonnell Ranges, and that one also was found drowned after heavy rain at Tempe Downs, a station situated about 120 miles west-south-west of Alice Springs These points will suffi-ciently define its range, so far as is known at present They do not appear to be very numerous Very few of the white men in the district had ever seen it, even though constantly travelling, and not many of the natives whom I came across recognized the well-executed drawing I carried with me It must be remembered, however, that I did not pass through the exact spot which so far appears to be its focus of distribution. Nor did a very considerable reward, which I offered, cause any speciconsecration femalia, which is othered, cause any speci-mens to be forthcoming between the first lot received, over two years ago, and that recently secured during my trans-continental trip. With a few exceptions, the an-mals have been captured by the aborignals, who, with

their phenomenal powers of tracking, follow up their traces until they are caught. For this reason they can only be found with certainty after rain, which sets the surface of the sand, and enables it to retain tracks that would immediately be obliterated when it is dry and loose. Nor are they found except during warm weather, so that the short period of semi-tropical summer rains appears to be the favourable period for their capture. For this suitable combination of wet and warmth, Mr. get them, and in all cases they were found during the day-time Perpetual burrowing seems to be the charactenstic feature of its life Both Mr Bishop and Mr Benham, who have seen the annual in its native state, report that, emerging from the sand, it travels on the surface for a few feet at a slowish pace, with a peculiar sinuous motion, the belly much flattened against the ground, while it rests on the outsides of its fore-paws, which are thus doubled in under it. It leaves behind it a peculiar sinuous triple track, the outer impressions, more or less interrupted, being caused by the feet, and the central continuous line by the tail, which seems to be pressed down in the rear Constantly on the look-out for its tracks, I was often deceived by those of numerous licards, which are somewhat similar in these respects

"It enters the sand obliquely, and travels under ground either for a few feet or for many yards, not apparently reaching a depth of more than two or three inches, for whish underground its progress can often be deterted by a slight cracking or miving of the suruse as a borer is made of the conical south with its horny protecting shield, and the powerful scoop-like claws (fore) are also early brought into play. As it disappears from sight, the bind-imbs, as well, are used to throw the sand backwards, which falls in again behind to throw the sand backwards, which falls in again behind for a few feet upon the surface, and then descends as before I could hear nothing of its making, or occupying at any time, permanent burrows. Both my informants land great stress on the phenomenal rapidity with which land great stress on the phenomenal rapidity with which continuity."

To these notes of Prof String I may add the remark that this is certainly one of the most extraordinary discovered in cology made of late years Notarystes (Typhole), as shown by Prof String's full and elaborate description and figures, is unquestionably 4 new and referred to a new section of the order Massupahia. We must all congratulate Prof Strings on his success in bringing before the world such an important novelty.

FRANCIS BRUNNOW, PHD, FRAS

WE regret to have to announce the death of Frances
Brunnow, whose fortune it was to earn in two
continents a reputation as an ardent astronomer and an
indefatigable observer and computer. He was not less
distinguished as a Professor at Ann Arbor, Michigan,
than when he filled the Chair of Astronomy at Dublin, and
was fortunate in his early career. Nearly fifty years ago
was fortunate in his early career. Nearly fifty years ago
he was one of the band of carriest astronomers that
Encke summoned round himself at Berlin, and thus he
became the firend and companion of Galle, of Bremiker,
and of DArrest. The time too, was increasing. Adams
and the issue of that well known drams was worked out
and the issue of that well known drams awa worked out

under the eyes of the late Dr. Brunnow He was present in the Berlin Observatory when Neptune was fire recognized as a planet, and an early, if not the earliest, notification of its discovery, that reached this country, came from his hand.

It would be tedious to recall all the results that his untiring industry wrought in the department of cometary classical investigation of the motion of De Vico's comet of short period. The close and eager search that was made for this comet, particularly in 1855, was not successful, and its ultimate career is unknown; but this fact does not detract from the merit of Dr. Brunnow's memoir on which a lesser reputation might rest. As a calculator of a high order, he will, however, be remembered for his work on the theory of some of the minor planets, as Flora, Victoria, and Iris-a work which to some extent was carried out during his Directorship of the Observatory of Ann Arbor, Michigan, to which he was appointed in 1854. Here, too, he published for a short time a periodical under the title of Astronomical Notices This journal had but a short life, and judging from its rarity must have had but a small circulation. A very different fate attended the publication of his "Lehrbuch der spharischen Astronomie.' first issued in 1851, and which has passed through several editions, been more than once translated, and is everywhere recognized as an authoritative text-book In 1865, on the death of Sir W Hamilton, Dr

In 1865, on the death of Sir W Hamilton, Dr Prinnow was appointed Andrew Professor of Astronomy in the University of Dublin and Director of the Dunair Prinnow was appointed Andrews Professor of Astronomy in the University of Dublin and Director of the Dunair researches in which his illustrous predecessor had been engaged had not left him sufficient lessure to superintend with activity the affiris of the Observatory, and the work of organizing and of placing it on a modern footing, deciquately equipped, fell to the lot of Dr. Brinnow, who object-glass, which had remained unmounted, was, under Dr. Brinnow's auspices, provided with an equatorial movement, and with it he carried out the researches in stellar parallax which marked alike his assiduity and his competence as an observer. This line of research, thus sellar parallax which marked alike his assiduity and his competence as an observer. This line of research, thus count of failing health and eyesight, and he has since lived privately, principally abroad. He died at Heidelberg, in an sixty-seventhy eart, to the deep regret, not only of his his sixty-seventhy eart, to the deep regret, not only of his his sixty-seventhy very to the deep regret, not only of his his sixty-seventhy very to the deep regret, not only of his his sixty-seventhy very to the deep regret, not only of his his sixty-seventhy very to the deep regret, not only of his by his teaching, whether as members of his classic

NOTES.

THE Astralasian Association for the Advancement of Science will hold it to fourth annual meeting at Hobart in January 1892. The first general meeting will take place on January 7, when Str James Hestow will reage the chart, and Sir Robert G C, Hamilton, Governor of Tasanana and President of the Tasanana Royal Society, will assume the Presidency, and deliver an address. Visits to places of interest in the immediate neighborhood of Hobart will be made during the time when the meeting is being held, and afterwards there will be executions to deflorent places in Tasanana. Application has executions to deflorent places in Tasanana. Application has received as the control of the Company, for passages at reclined rates to members of the British Association visits of Tasanana to attend the meeting at Hobart, and it is especied that this will be granted.

THE International Electro-Technical Congress was opened at Frankfort on-the-Main on Tuesday An address was de-

NO. 1141, VOL. 44]

27

livered by Dr. Stephan, Imperial Minister of Post and Tulgraphs. Some 650 members, of whom 15% were foregagers, stateded the proceedings. After the usual complimentary speeches, the following gentlemen were cleated Fresidents of the various Sections of the Congress .—Herr Stemens, of Rerim Mr. Preco, of London; M Henpitaltes, of Paris Signor Ferrare, of Turns, Herr Waltenhofen, of Venna; and Herr Kohlarusch, of Hanover. It was deceded that a special Section should be formed to consider the principles of legulation dealing with electro-technical matters.

The Crystal Palace Lietmeal Enhibition, to be opened on January 1 test, has received the sanction of the Board of Trade, and in duly certified as an International Enhibition, under the portunous of the Patients, Deagns, and Trade Marks. Act, 1852, The exhibits of Her Mayesty's Government will include thus trocal telegraphs and electrical apparatus, instruments, and appliances, as well as the modern apparatus and instruments now in use in the Postal Telegraph Deparations. I This exhibit will be arranged under the direction of Mr. W. H. Preece, F.R. S.

If has been suggested in America that steps should be taken to secure an International Conference of Electronans at the "Columbian World's Fair" "The time and place," asys the new Chicago Journal, Electrance, "are certainly suspicious, and as there are many questions in electrical science that are now awasting adjudication at would seem that it were only necessary that the invitation be made by the properly constituted bodes to have it meet with the hearty approbation of scientific men everywhere Could such a Convention be assembled it would do more than any other agency to bring together at the Columbian Exposition the most complete and varied displayed celectrical apparatise the world ever ware"

This International Agricultural Congress was opened on Monday at the Hugue by M. Millen, the President, who briefly reviewed the labours of the Paris Congress, dwelling upon its that the results obtained by that meeting would assist the avenues Governments in the legislative, administrative, and considerable of the property of the p

We have received an natimation of the sudden death, from apolexy, of Dr L Just, Professor of Botany at the Polyrechnkum, Carkvuhe, and Director of the Botanic Garden belonging to the same institution. Dr. Just was best known to the botanical world through the "Botanicker Yorksterekt, which has appeared under his name since its foundation in 1874 up to the present time, housely he resized the editorible in 1884.

MR. CHARLES JAMAGEL, well known as an unporter, breeder, and exporte of all knode of annuals, deel last Sonday at has residence in Bow. He was of German parentiage, and inherited from his father the business which be conducted with so much energy and intelligence. Many scientific collections, as well as specimens. He showed particular interest in the breeding of non-coasted Perunal greybounds, Japanese pages, and Madagascar, cais. The collection had last formed includes, the Thomas way, vogore loos, terms, and of the property of the pro

Titz number of visitors to the South Kensington Museum during the last month exceeded 120,000. This is the largest number in any one month since 1883, in which year the Fisheries Exhibition was held opposite to the Museum, on the ground formerly occupied by the Royal Horicultural Society. THE Staffordshire County Council have appointed Prof. D. E. Jones, B.Sc. (of the University College of Wales, Aberystwyth), as Director of Technical Instruction for Staffordshire.

THE Oxford Delegates responsible for the University Extension work have just published their Annual Report for the year ending July 31, 1891 No fewer than 192 courses of lectures were delivered. Of these, 90 were on historical subjects, 64 on natural science, 33 on literature and art, and 5 on political economy These figures show a small increase in the number of courses on history and literature, and evidence a marked increase in the attention that is being paid throughout the country to natural science On the other hand, political economy does not appear to be popular with those who are responsible for the arrangement of the lectures, and this circumstance the Delegates regret At several centres in the North of England the courses have been regularly attended by many hundreds of artisans, and the funds to defray the expenses of these lectures have been provided by working men societies The results of the examinations have in many cases been most satisfactory. In the opinion of Mr. York Powell "The paper classed as distinguished would have been accepted in Oxford as distinctly belonging to the honour class, the 'pass' standard is that which would be adopted in the Oxford pass school " Mr Lodge and Mr A H Johnson hear similar testimony to the efficiency and capacity of the students

Titte Timer has been printing an interesting correspondence on county museums, and we may hope that the discussion will lead to some practical results. There can be no doubt as to the need for such institutions. Properly organized, they might be of high educational valies, and they would preserve for posterity many objects of archoiological interest which are now in danger of being either destroyed or lot! The sum of the proposed measures built, however, as Tork Flower has unged, to be very clearly defined, and it would be concentrate that may be considered to be reported to be comparable to the control of the con

EVEX/ONE, interested in the scientific superts of agriculture was norry to hear that Miss Ownrool had felt in tecessary to reign her position as consulting entomologist to the Royal Agricultural Society. It is much to be regretted that understandings should have led to the severance of her connection with the Society with which she has also long been honourably associated. Fortunately her work as an entomologist is not to be interrupted, and she will continue to place her knowledge at the service of agricultursis.

THE Department of Agriculture in New South Wales is not likely to complian of lack of work. During the first three months of the Department's existence—March to May 1850—200 letters were received from farmers and others on matters of agricultural interest, during the same months of the year, 200 of the were received and fully natured. During the first tire months of the current year, over 1000 letters were written by the Department, giving specific advoc on matures, analysis of soils, because of the property of the prope

In the official statement relating to the work of the British Museum (Natural History) during 1859, reference is made to two new cases which have been placed in the central hall one of them illustrates external variation according to age, sex, and season, as exemplified in the well-known bird the Martin Charleston and the part of the case is a trended to lightwate the first of the case is a coupled by a group showing the simplest form of the case is accoupted by a group showing the simplest form of the case is accoupted by a group showing the simplest form of the remaining charlest control to a should be a successful to the case is a coupled by a group showing the simplest form of the resemblance, the general conformation of colour to shutual

surrounding. Various species of mismonals, birds, and reputies, from the Egyption desert, are arranged upon a ground consisting of the actual rocks and sand among which they were living. These specimens were collected in February 1890, and presented by Mr. F. S. Worthington. In the upper part of the case speciments are enhabled, chelly from the class of insects in which the limitation both of the form and colour of external objects is carried to various degrees of perfection and complexity. Among these is a group of Indian battlerflees [Kullham amakes], which, when at rest with their ungs closely, present a marvellous resemblance to deal leaves. Still further stages of complexity of imantion are shown in insects which closely reasonable, externally, others belonging to different families or even orders, appearately for purpose of protection.

M E. HECKEL, of Marseilles, has recently described an in teresting case of mimicry which may be frequently seen in the south of France The numic is a spider, Thomisus onustus, which is often found in the flowers of Convolvulus arvensis, where it hides itself for the purpose of snaring two Diptera, Nomioides minutissimus and Melithreplus origani, on which it feeds Convolvulus is abundant, and three principal colour variations are met with there is a white form, a pink one with deep pink spots, and a light pink form with a slight green hness on the external wall of the corolla. Each of these forms is particularly visited by one of three varieties of Thomasus The variety which visits the greenish form has a green hue, and keeps on the greener part of the corolla , that which lives in the white form is white, with a faint blue cross on the abdomen. and some blue at the end of the legs, the variety which lives in the pink form is pink itself on the prominent parts of the abdomen and legs. If the animal happens to live on Duklia resicular, the pink turns to red, and if it lives in a yellow flower-Anturhinum majus, for instance-it becomes yellow At first Prof. Heckel supposed the three varieties of Thomasus to be permanent, but he discovered accidentally that any one of these peculiarly coloured spiders, when transferred to a differ ently coloured flower, assumes the hue of the latter in the course of a few days, and when the pink, white, green, and yellow varieties are confined together in a box, they all become nearly

Ms. Theorous Baxy, according to a telegram received from him at Cape Town, has good reson to be satisfied with the results of his investigation of the Zimbabye runs. He is of opinion that the "finds" mamivakably indicate the form of worthing, the manner of decoration, and the system of gold snaclting practised by the vanished people who inhabited the buildings. He is now visiting other runs.

THE series of "One Man" photographic exhibitions at the Camera Club is to be continued during the coming water According to the Journal of the Club, there will first be an exhibition of photographs by Mr Ralph W. Robinson This will be followed by an exhibition of the work of Mr. J. P. Gibson, of Hexham.

AT a meeting of the Meteocological Society of Mauritus on July 30, it was stated that, on June 13 and 14, lait, thunderstorms occurred in that island. This, so far as was known, was the first instance of a thunder-torm having taken place snace the year 1801. There was a considerable increase of sunpois at about this time, and on June 14 a remarkable magnetic disturbance took place. Photographs of the latter part of the transit of Venus, on May 10 last, were exhibited. At sunrise the planet had already traversed about one half of its apparent path, and its apparance was perfectly round and intensely black. The time of tangential contact (at egress) was, as nearly as could be ascentianed, 81 soft m 36. A number of charts showing the winds and weather experienced by several vessels which encountered cyclones in December, Junuary, and Rebrary list were submitted; the greatest of the disturbances which had been experienced of late occurred from February 3-13. At the Observatory the barometer fell from 29 95s inches, at sh. am. on the 1st, to 29 40p inches, at sh. 5sm. am on the 6ft. Full details of these cyclones will be published by the reference to the "Allas of Cyclones Tracks," lately published by the Meteorn-logical Council, Dr. Meldrum stated that the preparation of an appendix was suffer consideration.

THE Report of the Meteorological Commission of Cape Colony for the year 1800 contains the results of observations taken at 45 principal stations, and monthly and yearly rainfall values at about 200 stations in the colony and neighbouring States. The observations are made chiefly by public officials, and by private centlemen who lend their aid. Summaries from a selected number of rainfall stations are also published monthly in the Government Gazette and in the Agricultural Journal. The expenditure for the year was only £378, so that, considering the smallness of the funds available, the results obtained are highly satisfactory, and the cost of instruments, which become the property of the observers after 5 years' continuous observations, is not inconsiderable. The Commission express the hope that their labours may lead to the discovery of the laws which govern the weather in those parts, and ultimately result in the issuing of trustworthy storm warnings. With this view simultaneous observations from various stations are telegraphed to various ports, where they are entered on sketch maps for the information of mariners and others

A CORRESPONDENT informs us that Dr. Sleich, of Berlin, has found that the subcutaneous injection of distilled water produces sufficient local anievitiesia at the point of insertion to allow small operations, such as opening a boil, to be made without pain.

THE following are some results of Herren Eister and Gettel's recent electric observations on the Sonnblick, described to the Vienna Academy -The intensity of the most refrangible solar rays, measured by their discharging effect on a negatively electrified surface of amalgamated zinc is about doubled on rising 3100 m from the lowland. The authors were unable to find other actino electrically active substances, even pure fresh snow and dry Sonnblick rock were not perceptibly discharged by light. Waterfalls may produce in a valley a negative fall of potential, and to considerable heights (500 m.) The morning maximum in fall of potential, observed regularly between 7 and 9 a m in the plain and in Alpine valleys, was absent at 3100 m. Before thunderstorms in July, the positive fall of potential sank gradually, in light showers, to mil, at which it remained sometimes two or three hours till completion of the electrical process in the cloud In thunder-clouds, or on low ground, during a thunderstorm, the atmospheric electricity usually changes sign after a discharge. St Elmo's fire (negative as often as positive) always accompanied thunderstorms. The observation that negative St Elmo's fire burns with blue flame, positive with red, was repeatedly confirmed

It is well known that the fox possesses an excellent "head for country." Referring to this subject in an interesting article in the current number of the Zoolgraf, Mr. Harting says a fox has been known to return seventy miles to his "earth," and thus not once, but three times. He was caught in Yorkshire, and sent intel, Lancashire to be hunted by the hounds of the late Mr. Fittherført Brockholes, of Claughton Hail, Garstang, and has identify was established by his having been marked in the ear by the fox-catcher This story Mr. Harting had from his fixed Captain F. H. Salvin, who was houng in Yorkshiles at the

time, and was well acquainted with Mr. Brockholes, whn gave him all the details

During the nesting season the male ostrich seems to be anything but an agreeable creature. In a paper lately read before the Royal Society of Tasmania, Mr James Andrew says that at that period the bird is most pugnacious, and may only be anproached in safety with great precaution. He resents the intrasion of any visitors on his domain, and proves a most formidable opponent. His mode of attack is by a series of Licks. The leg is thrown forwards and outwards, until the foot, armed with a most formidable nail, is high in the air, it is then brought down with terrific force, serious enough to the unhappy human being or animal struck with the flat of the foot, but much worse if the victim be caught and ripped by the toe. Instances are known of men being killed outright by a single kick, and Mr. Andrew remembers, whilst on a visit in the neighbourhood, that on a farm near Graaff Reinet a horse's back was broken by one such blow aimed at its rider. If attacked, a man should never seck safety in flight, a few yards and the bird is within striking distance, and the worst consequences may result. The alternative is to lie flat on the ground, and submit with as much resignation as possible to the inevitable and severe pummelling which it may be expected will be repeated at intervals until a means of escape presents itself, or the bird affords an opportunity of being caught by the neck, which, if tightly held and kept down, prevents much further mischief Under such circumstances, however, Mr Andrew has known a bird, with a badly-calculated kick, strike the back of its own head, scattering the biains-"a serious loss of valuable property to the former "

WE learn from the Tifts paper Caucasus that during an excursion to the sources of the Jiagdon, which was made recently by several explorers, no fewer than eight glaciers were discovered, are of which are not marked on the 5 versts to the inch from Styr khokh Pass The southern slope of the branchridge of the man chain, between the Kazbek and the Syrkhubarzon peak, has also been sketched from the Trussoff's l'ass, and it appears that several of the glaciers of this part of the chain are not represented on the great map, while perpetual snow is shown where there is none. The glaciers visited by the party proved to have very much changed then aspect since 1882. Several sulphur and non carbonate springs were visited in the frussoft's valley, and several interesting Alpine flowers in bloom were collected on the passes

A SECUL of the vegetation of British Baluchistan, with descriptions of new species, juilblished originally in the Linnean Society's Journal, has now been issued separately The author is Mr. I H Lace, who has had the advantage of Mr W. B. Hemsley's aid.

Its the Bulletins de la Nocidi d'Antirophòlogie de Paris (Iouthi excresa, val u Paris 1 and 3) the subject most prominently dealt with is the slow rate at which the population of France increases According to the report of a prolonged discussion on this question, there is much difference of opinion as to the causes to which the phenomenon must be attributed. The Bulletins also include interesting contributions on the Koubous, and antive tribe of Sumarts, by M. Zelle, a series of spoons of various spochs, by M. Capitan, the pre Columbian ethnography of Veneziels, by Dr. G. Merzano, justice in Ancient Egrpt, by M. Olivier-Beauregard; and religious evolution in the region of the Congo, by M. Clement Rubbean.

THE second part of the Catalogue of Mammalia in the Indian Museum, Calcutta, by Mr. W. L. Sciater, has just been issued. The first part was compiled by Dr Anderson, the late Super-

intendent. The total number of species included in the Catalogue amounts to 590, of which 276 are found within the Indian Empire, and 314 are exotic.

The Smthonian Institution has issued a set of well-differentian, by Leonhard Seigneger, for the use of cells ctors, who, without being herpetological experts, desire to procure for the U.S. National Muccum specimens of the repitales and batra-chanas which they may be able to guther in the neighbourhood of their residence or white travelling. The same institution of their residence or white travelling. The same institution of their residence or white travelling. The same institution of their residence of their confidence of their residence of their residence

STUDENTS will be glad to welcome the fourth edition of Prof. Mines Marshall's well-known work on "The Frog. an Intro duction to Anatomy, Hatology, and Embryology "The eather explains that the chapter on embryology has been in great part rewritten, and that some new figures have been added The entire book has been carefully revised.

THE additions to the Zoological Society's Cardens during the past week include a Dorsal Hyrat (Hyrat advirably from Sierra Loose, presented by Mr. Reginalal Brett, a Common Polecat (Mustice patient), British, presented by Mr. F. D. Lea Smith, a Ring necked Parakect (Vollectria tropystary) from India, presented by Mr. Browen, an Australian Timcknee (Editertrial Augustian) from Austrials, pre-sented by Mr. Perkinand von British, presented by Mr. British, pre

OUR ASTRONOMICAL COLUMN

SOLAR OBSERVATIONS—In Compter surder for August 2s. Frof Teaching gives a risum of the volar observations made at the Observatory of the Roman College during the second quarter of this year Spots and facult lave been observed on 73 days, viz 25 in April, 23 in May, and 25 in June, The following are the results obtained—

	Relativ	e frequency	Relative :	Number	
1891	of spot-	of days without spots	of spots	of facula	per day
April	9'24	0 00	24 56	55 60	2 36
May	14 35	0 00	48 14	51 82	4 00
June	16 88	0 00	47'00	89 38	3 80

The distribution and magnitude of the prominences observed are as follow ---

1891	Number of days of	Mean number	Mean height	Mean extension	
April	observation 18	7'50	42 3	ı°5	
May	21	4 62	37 3	14	
Turne					

It is worthy of remark that there was a secondary maximum in May in the case of spots, whilst a secondary minimum is indicated by the observations of prominences

indicated by the observations of prominences.

a manner which would have indee justice to their nexts. I he want pleasantly graped if such a course were adopted. Unfortunately, some of the leading physicists, notably fix william Thomoson, Lord Raypigs, and Frof Frigarenil, were the charge in the control of the leading physicists, notably fix the control of the course o

After the President's address on Thursday mining, Prof. Newton commissated a most interesting account of the action of Jupiter on small boths, passing near the planet, in which he quivalent the professional profes

Mr. W. E. Wilson resit a paper on the absorption of heat un the solar amougher, and exhalted some of the apparatus he had used in the investigation. The unfool of observation he had used in the investigation. The unfool of observation acrows the thermo-electric junction of a floys radio-incrementer. He finds that the solar radiation from the extreme period of the dark of attained, by the standard period of the dark of attained period in the extreme period of the dark of attained period in the entirely from that of the moon, in which there is little or no exhibit period of different parts of the varieties of the varieties.

face. This difference is attributable to the absorption of heat in the solar atmosphere, which will necessarily be much more marked for the peripheral than for the central portions of the

Mr. G. H. Bryan presented an elaborate report on researches relative to the second law of thermodynamics, in which is described an exceedingly simple mechanical representation of Carnot's reversible cycle.

Friday was devoted to papers on electrical aubjects. Prof. Friday was devoice to paper on electrical ampiects. Prof. Andrew Gray read a paper on the electro-magnetic theory of the rotation of the plane of polarized light. Sir William Thomson's explanation of the phenomenon rests on the supposition that the ether has embedded in it a large number of small gyrosita. Prof. Gray showed that the ordinary Maxwellian equations for the phenomenon were obtainable on the supposition of the existence of a closed chain of small magnets embedded in the undisturbed medium, which set themselves with their axes to the

undistursed medium, which set themselves with their axes is the direction of propagation of the ray as soon as the medium was magacitzed in that direction.

This paper was followed by a most interesting communication from the President, in which he gave as account of preliminary experiments to accretant fit the other is disturbed in the neighbourhood of a rapidly moving body—in other words, to accertain whether the ether behaves as a viscous fluid. Allusion was first of all made to the experiments of Arago, in which he endeavoured to determine whether or not the ether was stagment with respect to the earth by measuring the refractive index of a (if it exist) will flow in one direction or the opposite through the prism Arago found no such shift, indicating that the ether was stagnant with reference to the carth Fresnel, Fizeau, and Michelson had also studied theoretically or experimentally the ratto of so called "bound" ether to "free" ether The problem which Prof Lodge set himself to determine was whether a disk moving with great rapidity would or would not drag after it the other in its immediate neighbourhood. Two parallel co-axial disks of steel were arranged to spin at an enormous rate Rays of light from a single source were allowed enormous rate. Rays of fight from a single source which half the to fall on a glass plate feelily silvered so that about half the light was transmitted and half reflected. By means of additional reflectors the two beams passed in opposite directions several times round in the space between the two disks, and were then observed in a common telescope and made to give interference bands. In this way, assuming viscosity of the other, the one beam would have its velocity increased, the other would have its velocity retarded, with the result that a shift of the interference bands would be produced So far, however, no such shift has been observed

beas observed Prof. D. E. Jones gave an account of some experiments made by him at Bonn on electric waves in wires. Measure ments of the electrical disturbance at different points of a wire, in which stationary waves are set up, were made quantitatively by patting a thermo-electric pattorion in the circuit at different points are supported by the pattern of the pa explanations were forthcoming
A communication was read from Lord Rayleigh, relating to

the reflection of polarized light from liquid surfaces. He finds the renection of polarized light from liquid surfaces. It is note that the light reflected at the polarizing single, from clean liquid surfaces, is only very slightly elliptically polarized, if, however, the surface be ever so slightly contaminated, the amount of elliptically polarized light in the reflected beam is enormously

increased.

Saturday was devoted principally to the consideration of papers on electrolysis. Mr. Shaw's report on the present state of our knowledge in electrolysis and electro-chemistry included a tabular compilation by Mr. Fitzpatrick of the electrical properties of soluble sails at different temperatures, and for different concentrations.

Mr. J Brown read a paper on Clausius's theory of electro-lytic conduction, and on some recent evidence for the dissocia-tion theory of electrolysis, in which he gave an account of experiments with so-called semi permicable membranes. The explanation of their filtering qualities simply depends on the membrane acting as a conductor

memorate acting as a continuous Mr Chattock gave an account of some important quantitative experiments which he had made on the discharge of electricity from points from which he finds that it is the air round the point rather than the metal surface itself which offers resistance to the

rainer inan ine inerai suince each adacharge.

On Ignday the meteorological and allied subjects were taken. The Rubes of various Committees appointed to deal with meteorological subjects were read.

Dr Johnstone Stoney read an interesting paper on the cause of double fines in the spectra of gases. He assumes that the

and he illustrated the simple case of sodium vapour by means of a pendulum oscillating to and fro, but with an apsidal motion.

He stated that the application of astronomical methods of calculation to molecular motions of sodium vapour gives rise to a double D line instead of to a broadening of the line as might at first sight he imagined. In the discussion which followed, Mr. Webster stated that Frof Michelsoa, who was endeavouring to determine the metre in terms of the wave-length of light emitted by a vibrating atom, had found by the interference method that all the mercury lines are the in double.

Dr. Copeland exhibited a model to explain the probable ture of the bright streaks on the moon. He attributes the nature of the bright streaks on the moon. He attributes the appearance of the streaks to the existence of transparent spheres on the moon's surface, which reflect the light from the posterior surface so as to be only visible in the line of light

During the morning the President interpolated some observa-tions dealing with the effect of light in modifying the effect of the gravitational attraction of the sun on small particles. When the gravitational attraction of the sun on small particles. When sunlight falls upon a body, a very small repulsave effect sproduced, amounting to about 67 dynes per square meter. Thus, for example, during an eclipse of the moon about 1000 tons are suddenly applied, but this small force is incapable of producing any observable effect on the motion of our astellite. The smaller the body, the larger, of course, the surface exposed relatively to the mass, and therefore the greater should be the effect produced For a certain size of particle (about that of a grana of dust) the gravitational attraction and light repulsion should balance one another The effect is clearly independent of distance

of distance. "Da Tuesday, after the Report of the Committee on Electrical Standards, read by Prof. Carey-Footer, and an account of an action of Clark collish there was armonged a point discussion with Section of Clark colls, there was armonged a point discussion with Section 65, on "Units and their Nomenclature," which was opened by the President, who suggested that the discussion should, as far as possible, be confined to electrical units, and that the mechanical units should be left to a later period. He discussed at some length the relative advantages and disadvan-tages of the various names for the unit of self-induction, secohm, quadrant, heary, &c, and expressed himself as of opinion that the quadrant, which was really an angular measure, but which was frequently used as a linear measure, was very objectionable in that it indicated that the uait of self-induction was a length, in that it indicated that the uall of sein-induction was a length. He was, therefore, of opinion that some aame with a less obvious meaning, such as that of a person, was very desirable. He thought also that the secohm was too large for practical purposes, and that some sub-multiple such as 1958 would be preferable

The President was followed by Mr. Procee, who referred to the work of the British Association Committee on Electrical Standards, which had lasted now for thirty years, and expressed the opinion that it would be undesirable to interfere in an with the old standards now about to be legalized by the Board

of Trade

Prof Stroud read a paper on some revolutionary suggestions on the nomenclature of electrical and mechanical units, in which he advocated selecting 100 cm, as the unit of length, 10-9 gm. as the unit of mass, and I see as the unit of time to form the basis of a new practical system of units. He also explained the details of a system of automatic nomenclature for C.G.S. and other units, which he thought should be taken into consideration before any fresh names were authorized. The special feature of the system is that every label is self-explanatory.

the system is that every label is self-explanatory.

Dr Johnstone Stoney thought the old system should remain intact, and that the proper way to deal with the subject of nomenclature was to indicate sub-multiples by numerical prefixes, e.g. he would call a microfand a sixth farad, and the capacity of a Leyden jar would be about a tenth farad. Gilbert, and that of the unit of magnetism should be a Gilbert, and that of the unit magnetic field a Gauss.

Prof. Carey Foster thought that if the volt and ampere were

made ten times as great, fresh names, such e.g. as "gal, from Galvani, should be introduced.

rous oursain, should be introduced. Prof Rucker laid stress on the importance of recognizing the fact that we possessed at present no definite knowledge as to the absolute dimensions of any electrical or magnetic unit, and therefore it was undesirable to introduce names and the stress of the property of the property

knowledge
Prof S P Thompson drew attention to the desirability of

distinguishing between scalar and vector quantities in our di-

Prof. Grav disapproved of the term electromotive for thought it was a term which could scarcely be eradicated now Each speaker, in fact, discussed the subject from his own point of view, with the result, as the President remarked, that the time allotted had only served to open the discussion, but he hoped that it would be continued in the technical journals during the year, so that some definite conclusions might be arrived at in

1892. Wednesday morning was devoted to clearing off arrears. Wednesday morning was devoted to clearing off arream. Prof. S. P. Thompson read two optical papers, one on the measurement of lenses, and a second on a new polarizer. In this instrument the polarization is effected by reflection from prime is used in addition. This arrangement has the dis-advantage that the axis of the beam undergoes a translational shift, so that rotation of the polarizer is out of the question. In get over this difficult two more reflection are introduced, or we quarter wave plates may be used, one of which converts the plane polarized light into creatingly polarized light, while the

plané polarazed light into circularly polarazed light, white the other reconverts into light plane polarazed in any armitto on a new method for determining v. The method is aimitted in the present to Aprico and Perry's, and gave as a result in the pre-liminary experiments 2 9/9 × 10¹⁰. For the present to a profession of the professi eeptible at considerable distances

Prof J V. Jones, in describing some experiments on the periodic time of tuning forks, maintained in vibration electrically, stated that dry platinum platinum contacts do not work satisstated that ary putanum pitanum contacts on not work satisfactorily, whereas the results obtained with mercury contacts are much better, at all events when changes of temperature are carefully guarded against.

Mr. F T Trouton described some interesting experiments to

determine the rate of propagation of magnetization in iron A large coil of iron wire, from 8 to 12 feet in diameter, was large coil of iron wire, from 8 to 12 beet in diameter, was supplied with one fixed coil wound on it, and through which the alternating current passed. A second exploring coil was connected up with a telephone, and one experiment consisted in endeavouring to find out the positions of nodes and inter-nodes in the magnetized material from which it might have been possible to have determined the length of the wave of magnetization for a definite period of alternation. Nodes were observed in the half of the ring remote from the magnetizing coil, but these were easily ascertained not to be the ones sought for, because their position was not found to depend on the period of alterna-

The President attributed the effects to mechanical vibrations excited by magnetization,

CHEMISTRY AT THE BRITISH ASSOCIATION.

THE proceedings of Section B at Cardiff were not felt to be as interesting as on some previous occasions. Several wellas interesting as on some previous occasions. Several well-known chemists were not present, and no set discussions on subjects of general chemical interest, which have been special features at other times, took place. Still, in the conres of the meeting several papers of very considerable importance were read, and provoked valuable comments. The Fresteden's Ad-dress was listened to by an enhustrastic audience, and his remarks, together with several of the papers contributed during the meet-

together with several of the papers contributed during the mestga, should give a fresh imputs to the study of the mestals the

at the same time. The results so far obtained are to be revarded as preliminary.

Prof Vivian B Lewes read a paper on the spontaneous ignition of coal. His experiments lead him to reject the explanation of Berzelius, which attributes spontaneous ignition to the oxidation of pyrites contained in the coal The heat given off by the combustion of the pyrites present in the most dangerous kind of coal, even if localized, would not be sufficient to raise kind of coal, even it localized, would not be sumcient to raise the temperature of the adjacent coal to the signition point. The cause of apontaneous signition of coal is to be found, rather, In its power, especially when finely divided, of absorbing oxygen, which causes the slow combustion of some of the hydrocarbon constituents even at the ordinary temperature. The action may increase under favourable conditions until ignition of the coal result. The risk is greatest with large masses of coal, and with results. The risk is greatest with large masses of coal, and with the oritinary art supply on board ships. The excitation increases rapidly with the initial temperature of the coal, so that call first are found to occur most often on ships frequenting tropical climates. It may be roughly estimated that the absorbing power of a coal for oxygen is proportional to its power of taking up

mosture In the discussion which followed, Prof Bedson mentioned his experiments on the heating of coal-dust at various temperatures up to 140° C. He had noticed that in some cases com-

bustible gases were given off by the coal

A feature of special interest was the exhibition by Ludwig Mond of specimens of nickel-carbon oxide and metallic nickel obtained therefrom In the paper read in conjunction with obtained therefrom. In the paper read in conjunction with metable an account was given of the discovery and properties of the above compound. The physical properties of the above compound. The physical properties of the above compounds the physical properties. Chemically, include carbony is most inactive, namesous experiments made to introduce the evrhonyl group into organic control properties. The physical properties of t or sulphur, the process is entirely successful on a laboratory scale Such ore, or matte, or speiss, is calcined, reduced by water gas at 450°, cooled down to a suitable temperature, and treated with earbon monoxide in a suitable apparatus. On exproving a heated surface to the gas containing nickel earbon-oxide, it is possible to produce, direct from such gas, articles of solid nickel, or goods plated with nickel, resembling in every way those obtained by galvanic deposition of metals, and repro-ducing with the same exactitude and fineness any design upon such articles This result can also be obtained by immersing heated articles in a solution of nickel carbon oxide in such solvents as henzole, petroleum, tar oils, &c , or by applying such solution to the heated articles with a brush or otherwise

A specimen of iron-carbon-oxide was exhibited, which Messes. A specimen of iron-carton-oxide was exhibited, which Meist-Mond and Langer have obtained as an ambet coloured liquid, which, on standing, deposits tabular crystals of a darker colour, and solidines entirely below - 21° Ct on amass of needleshiped crystals. It boils at ro2° C, but leaves a small quantity of green-coloured oil behind Several analyses and vapouried with the part of the colour o

whither a pure substance has been obtained or a mixture of several tron carbonyls. The authors hope aboutly to publish a full account of this interesting substance, which difficult in the substance of the subst induction coil at ordinary temperature, and if a piece of glass be placed underneath the gold in the tube, on passing the current placed undermeath the gold in the tube, on passing the current an entaillic mirror appears on the glass, increasing in thickness to a leaf, which can be peeled off, and which is perfectly homo-geneous. Films of silver and platinum can also be obtained it is found that different metals thus treated evaporate at different it is communate direction means thus treated evaporate at directinates, one or two, such as aluminum and magnosimi, heing apparently non-volatile. It is thus possible, in the case of the administrative of alloy discovered by Prof. Roberts-Austen, to separate a large portion of the gold from the aluminum by clearing a portion of the gold from the aluminum by clearing a portion of the gold from the aluminum by the central evaporation.

T Turage gave an account of experiments which he had made to discover the cause of the red blotches which often appear on the surface of brass sheets on rolling, and which are a great source of annoyance to Birmingham manufacturers. They are

due to the erosion of the zine by the chlorides present in the solution in which the brass has been pickled, and in the water

solution in which the brass has been pickled, and in the water in which it is afterwards washed, care not being always taken to prevent such chlorides from drying on before rolling.

A P Laurie described the experiments he has made to determine the electromotive forces of various alloys with a view to establishing the existence of definite compounds among them. His earlier experiments will be found in the Journ. Chem. Soc., 1888, p 104. His recent work leads him to conclude that a compound of gold and tin of the formula AuSn exists, a sudden rise of electromotive force being observed when the proportion of tin in the alloy exceeds that required by the above formula.

of in in the alloy exceeds that required by the above formula. Compounds do not appear to exist among the alloys of unc, cadmium, lead, and tin Prof. Roberts-Austen exhibited and described his self-recording pyrometer. In this instrument, thermal junctions of platinum and platinum containing to per cent of rhodium are connected with a galvanometer The spot of light from the mirror of this. I caused to fall on a with before which a photographic plate passes at a given rate, by which means a curve is traced, corresponding to the variations in temperature of the heated thermal junction. The other junction is kept at a con-stant temperature by immersion in water. Temperatures up stant temperature by immersion in water. Temperatures up to the melting-point of platimum can be determined with an occuracy of 10°. The curves of cooling of several alloys have been determined. The alloy of gold and aluminum differs from others, such as that of platinum and lead, in that there is no break in the curves at the point of shalifaction of the alloys. entitled. "The Relation between the Composition of a Double-Salt and the Composition and Temperature of the Lanout on

Salt and the Composition and Temperature of the Liquid in which it is formed." The authors have obtained a large number which it is formed. The authors have obtained a large number of double chlorides of ammonium and ron by crystallizing from solutions containing varying amounts of ferrous and ammonium chlorides, and maintained it different temperatures. The convention of the contract of may exist in other cases

Prof Dunstan, in the discussion which followed, described a series of double cyanides of zinc and mercury, of complex composition, which he had obtained by precipitation

composition, which he had obtained by precipitation In a preliminary account of some experiments he is making on the action of oxide of cobalt in causing the evolution of oxygen from hypochlorites, Prof. M'Leod showed that, on boiling an alkaline solution of a hypochloric alone, some oxygen is evolved and chlorate formed, so that the action is probably

gen is evolved and chlorate formed, so that the action is probably somewhat complex in presence of oxide of collective year. He Report on the Isomeric Naphthalene Derivatives. The study of the dichloransphthalenes has been completed. Of the twefve reported to exist, only ten could be obtained. This number is that required by theory. Of the fourteen theoretically possible trichloronaphthalenes, thirteen have been obtained. The compound containing the chlorine atoms in the positions I 2 I' is missing These results put it beyond question that naphthalene has a symmetrical structure. Its exact inner configuration has mas a symmetrical structure. Its exact inner configuration has yet to be dealt with. Experiments have been made with a vitte to determine the inanner in which substitution takes place. It appears probable that an addition product is always first formed.

Prof. Rucker gave an account of the experiments made by Prof. Rucker gave an account of the experiments made by Prof. Ruckers Austen and humself to determine the specific heat of the self-recording pyrometers above ment model and the self-recording pyrometers and the special fless in recrease regularly up to the melting-point, which is not very definite. About the point there is considerable aboptions of literath feat. The mean specific heat physicars and apply was found the way and between 25% and 1907, 332 Prof. Pt. Clowes described an apparatus for testing asfert-limits and the self-recording and the self-recordi

paraffin, in which the mixture of fire-damp and air could be made, the safety-lamp being afterwards introduced. A lamp

was exhibited which would indicate in this apparatus '25 per

was exhibited which would indicate in this apparatus. 2) jet-ent of fire-dampingoo described the results he has obtained on repeating the experiments of Kruss and his colleagues on the sare earths, which caused them to announce the probable exist-ence of about twenty new elements. Although he has worked on material from the same locality and of the same appearance as that used by the above-named workers, he has entirely failed to confirm their results, at any rate with regard to the didymlum fraction. He considers that the absence of certain lines noticed by them in the didymum spectrum may be due simply to dilu-tion, and do not indicate a splitting up of that element. On making his solutions sufficiently strong, he was able in all cases

to obtain the lines

Prof. Ramsay drew attention to the remarkable properties Prof. Ramsay drew attention to the remarkable properties which are exhibited by the hquids obtained by passing excess of hydrogen sulphide into solutions of certain metals, and afterwards expelling the excess of hydrogen sulphode by hydrogen Mercures sulphide treated in this way dissolves to a dark-brown solution. Artimony and assemic sulphides also dissolve. On examining the mercury solution under the microscope, brown examining the mercury solution under the microscope, bown particles are seen in a state of rapid motion. With natimony solution, particles are not vauble, but a sort of granular movements of the state of the state

a state of mpod but erecum-eribed motion.

One of the few papers on organic chemistry was reach by J. J.

A paper was read by C G Moor, on a new method for the disposal of sewage This consists in the application of a method disposas of sewage — int consists in the application or a memor-invented by Mr. Rees Rece for obtaining far ammona, &c.-A kind of Inne-kin is employed, with a forced draught, con-nected to a sense of condenser. The operation is conducted in such a manner that the material in the lower part of the furnace is kept in active combistion, it is head distill the material directly swep, an active community, in their think to serve as fuel for the succeeding charge. Eighty per cent. of the theoretical yield of ammonia has been obtained. In order for the process to be commercially successful, it seems that the use of lime in ressing the sludge should be avoided at all costs, as, if much

to be commercially used creams an accurate many measures are made in the case of the case

SOME DIFFICULTIES IN THE LIFE OF AOUATIC INSECTS

M/E understand insects to be animals of small size, furnished WE understand insects to be animals of small size, furnished with a hard kin and six legs, breathing by branched artubes, and commonly provided in the adult condition with wings. The animals thus organized are pre-emisently a dominant group, as is shown by the vast number of the species and inclinicalist, their universal distribution, and their various

The insect type, like some fruitful inventions of manor lithography, for instance—has proved so successful that it has been found profitable to adapt it to countless distinct purposes

I propose to consider one only of its infinitely varied adapta-

tions, viz its adaptation to aquatic life.

There are insects which run upon the earth, insects which fly in the air, and insects which swim in the water. The same might be said of three other classes of animals—the three highest—viz mammals, birds, and reptiles but insects out insects of all other classes of animals in the variety of their modes of exist-But insects surpass Owing to their small size and hard skin, they can burrow into the earth, into the wood of trees, or into the bodies of other There are some insects which can live in the water, animals are the some insects which can be a first and the mammal, bird, or reptile does, coming up from time to time to breathe, but constantly immersed, like a fish. This is the more remarkable because insects arc, as a class, and breathers. Air tubes or trachese, branching tubes, whose walls are stiffened by spiral threads, supply all the tissues of the body with air That such an animal should be hatched in water, and wild air. I flat such at stiller insurersed, a thing which actually happens to many insects, is n matter for surprise, and implies many modifications of structure, affecting all parts of the

body

The adaptation of insects to aquatic conditions seems to have The adaptation of insects to aquatic conditions seems to have been brought about at different times, and for a variety of dis-tanct purposes. Many Dipteron larva burrow in the eastli-Some of these request the damp earth in the neighbourhood of streams, others are found in earth so sorked with water that it might almost be called mud, though they breath by occasionally taking in atmospheric air. In yet more specialized members of the same order we find that the larva inhabits the mud at the the same order we find that the larva inhabits the mud at the bottom of the stream, and depends for its re-paration entirely upon oxygen dissolved in the water. The motive is usually that the larva may get access to the decaying vegetable inatter found in slow streams, but so ne of these larvae have carmivorous propensitles Other insects merely dive into the water, coming up from

Other insects mertly dive into the water, coming up from time to time to breath, or a skate upon the surface Nearly every order of insects contains aquatic forms, and the total number of such forms is very large I believe that all are modifications of terrestrial types, and it is probable that members of different liamilies have often betaken themselves to

The difficulties which aquatic insects have to encounter begin with the egg It is in most cases convenient that the egg should while the laid in water, though this is not indispensable, and the winged, air-breathing fly is, as a rule, ill fitted for entering water. Some insect eggs hatch if they are merely scattered, like grains of sand, over the hottom of a stream, but others must be laid at the surface of the water, where they can gain a sufficient supply of oxygen. If the water is stagnant, it will suffice if the eggs are buoyant, like those which compose the egg-raft of the gnat, but this plan would hardly answer in running streams, which would carry light, floating eggs to great distances, or even sweep them out to sea. Moreover, floating eggs to great distances, or even sweep them out to sea. Moreover, floating eggs are exposed to the attacks of hungry creatures of various kinds, such as burds or predatory musect larve. These difficulties have been met in the cases of a number of insects by laying the eggs in chains or strings, and mooring them at the surface of eggs in chans or strings, and mooring them at the surface of the water. The eggs are invested by a gelations envelope, which swells only, the moment it reaches the water, into an the surface of the surface of the surface of the surface than one purpose. In the first place it makes the eggs no allphery that birds or insects cannot grasp them. It also spaces to be eggs, and enables each to get it six share of arr and sim-light. The gelatinous substance appears to possess some anti-gible property, which presents water-models from attacking the

¹ Evening Discourse, delivered before the British Association, Cardiff, 1891, by L. C. Miall, Professor of Biology in the Yurkshire College

eggs, for, long after the eggs may mission of the frog, which are lead in the staguant water of ditches or ponds, float free at the laid in the staguant water of ditches or ponds, float free at the surface, and do not require to be moored vanile are laid in the form of an adhesive band, which holds are laid in the form of an adhesive band, which holds are laid in the form of an anyatte plant. Some insects, eggs, for, long after the eggs have hatched out, the transparent shall are laid in the form of an adhesive band, which notes firmly to the stem or leaf of an aquatic plant. Some insects, too, lay their eggs in the form of an adhesive band. In other cases the egg-chain is moored to the bank by a slender cord.

The common two-winged fly, Chiionomis, lays its cggs in trus-parent cylindrical ropes, which flost on the surface of the water During the summer months these egg ropes, which are nearly an inch in length, may readily be found on the edges of nearly an men in length, may readily be found on the edges of a stone foundation in a garden, or in a water trough by the side of the road. The eggs are arranged upon the outside of the rope in loops, which bend to right and left alternately, forming simous lines upon the surface. Each egg rope is moored to the bank by a thread, which passes through the middle of the rope in a series of loops, and then returns in as many reversed and an a sense of hosps, and then teturus in as; many recvered and ornelapping loops, so as to give the apprenance of a tools-witch ornelapping loops, so as to give the apprenance of a tools-witch accedie subnout breaking. If the egr reige is dispect into beal wine they are in solide, owing to their transparency. The subnout of the subnou signal shape when released By mean, of these threads, original shape when released. By mean, of these threads, feruly intervoven with the muchage, of the egg rope, the whole mass of many hundreds of eggs is firmly moored, yet so moored that it floats without strain, and rises or falls with the stream. The eggs get all the sun and air which they require, and neither predatory insects, nor birds, nor water moulds, nor rushing currents of water, can injure them

The eggs of the caddis fly are laid in larger ropes, which, in some species, are very beautiful objects, owing to the gras-green colour of the eggs. The egg raft of the gnat, which has often been described, is well suited to flotation in stagnant often been described, is well suited to flotation in streams where, and is field very expect of the air, a point of unusual im-portance in the case of an insect which in all stages of growth scens to meel the most efficient means of respiration, and whose ggg are assally laid in water of very doubtful purity. The lower or submerged end of each egg opens by a lid, and through this opening the laws at length is super-

this opening the larve at length excapes. The eggs of water haunting insects are in many ways particululy well suited for the study of development. The eggs of chronomus, for instance, can always he protucted during the summer mouths. They are so transparent as to admit of exammation under high powers of the microscope as living objects, and as they require no sort of preparation, they may be replaced in the water after each examination to continue their develop me nt This saves all trouble in determining the succession of must This saves all trouble in determining the succession of the different stage—a point which awailly presents difficulties to the embryologist. The whole development of the egg of Chronomaus is completed in a few days (there to us, according to temperature), and in it therefore an easy matter to follow the present thoughout with the help of three or four chains of eggs. When the larve are hatched, and escape into the water, new ficulties arise Some have to seek their food at the surface difficulties arise of the water, and must yet be always immersed, others live upon food which is only to be found in rapid streams, and these run enous risk of being swept away by the rush of water All need selious risk of being weigt away by the reach of water. All need at least a moderate supply of coygen, which has either to be drawn from the air at the surface, or extinated from the water by special organ. The difficulty of breathing r, of course, greatly mneeased when the larva seeks its field at the bottom of fool attenues, as is the case with cottain Diptira. The larva of Chronomus, for example, feeds upon vegetable matter, often in a state of decay, which is obtained from the mult at the bottom of slow streams, and in this mud the larva makes burrows for of slow streams, and in this mid the larva makes burrows for tuelf, cementing together all vorts of materials by the secretion of its anivary glands, drawn out into fine vilken threads. The burrows in which the larva lives furnish an important defence against fishes and other enemies, but they still curther increasagainst resides and other enemies, but they still further increas-ine difficulty of procuring a supply of air Hence, the farva frequently quits its burrow, especially by night, and swims towards the surface. At these times it loops its body to and fro with a kind of Isshing movement, and is thus enabled to advance and first in the water. From the well-serated water at the surface of the stream it procures a free supply of oxygen.

which becomes dissolved in the abundant blood of the larva which becomes dissolved in the abundant blood of the larva Four delicate tabes filled with blood, which are carried upon the last segment of the body, are believed to be especially insteaded for the taking up of dissolved oxygen. The Irachesi system is radimensary and completely closed, and hence gastons in radimensary and completely closed, and hence gastons which have been completely closed, and hence gastons with the body of the larva, and used with the greavest conomy. It is apparently for this reason that the larva of Chronomus contains a blood-red pigment, which is identical with the hancefullowing of which the present contains a blood-red pigment, which is identical to the contained of t acts in the Chironomus larva as it does in our own bodies, as an oxygen carrier, readily taking up dissolved oxygen, and parting with it gradually to the tissues of the body.

It is instructive to notice that only such Chironomus larve as live at the bottom and hurrow in the mud possess the red hæmoglobin Those which live at or near the surface have hemoglobin Those which live at or nest the surface have colourless blood, and a more complete, though still closed, tra cheal system The larva of the carnivorous Tanypus, which is colourness bloom, and a more complete, mongh duri chooled, the most complete than a more than the control to th ably statisfactory reason for the occurrence of hemogloban in a number of animals whose reprinciply variases in limited, and whose are reprinciply and the state of the state of the state whose are reprinciply and the state of the state of the state whose are reprinciply and the state of the state of the state animals under the same conditions manage perfectly well without hemogloban. Such admission is not a logical relutation of the explanation in might fairly put forward the baldness of man-riciple and the state of the state of the state of the explanation would not be ampured by any more wife, and that explanation would not were way. The facts its that the respiratory needs, even of closely alled animals, vary greatly, and further, there are more ways than one of acquiring and storing up oxygen in their bodies.

Either the storage-capacity for oxygen of the Chironomus Either the storage-capacity for oxygen of the Chronomas larva is considerable, or it must be used very carefully, for the larva is considerable, or it must be used very carefully, for the of dutilled water, boiled it for three-quarters of an hour, closed it tught with an indisrubber bung, and left it to cool. Then six larva were introduced, the small space above the water was replaced, and the larva were watched from day to day. Four of the larva surrived for forty eight hours, and one till the fifth day. Two of them changed to pupe. Nevertheless, the water was from the first exhausted of oxygen, or nearly so

The Chironomus larva is provided with implements suited to its mode of life The head, which is extremely small and hard. carries a pair of stout jaws, besides a most complicated array of hooks, some fixed, some movable The use of these minute hooks, some fixed, some movable. The use of these mands appendages cannot always be assigned, but some of them are apparedly employed to guide the sulky threads which issue apparedly employed to guide the sulky threads which issue for a first or the superior appared to those progression and help the larva to These are mainly used in progression, and help the larva to think tiself to and fro in its burrow. A smaller, but longer pair of hooked feet is found at the end of the body. This hander pair serves to a glaste, the animal to its burrow when it atteches forth in search of food

both in search of food

Creeping aquatic larve, such as Ephydra, possess several pairs

of legs in front of the last pair, but the burrowing species, such

as caddia-works, agree with Chronoms, not only in their mode

of life, but also in the reduction of the abdominal legs to a single

pur, which are compensoraly hooking of their pairs of the pairs

little more than an implement for biting and spinning, by no

means such a seat of intelligence as it is in higher animals. In Chironomus it contains no brain, the eyes are mere specks of pigment, and the antenne are inagmicant. But the head of pigment, and the antennee are insignificant. But the head of the flu nedoese the brans, and beare slaborate organs of special sense—many facetted eyes, and in the mule beautiful plumed sense—many facetted eyes, and in the mule beautiful plumed replants the fact that the bead of the flux not developed within the larval head, but in the thorax. It is only at the time of papation that it becomes everted, and it as pipendage assume the position which they are ultimately intended to occupy. At length the Chromosous wangels could for the result skin, and

is transformed into a pupa. It no longer requires to feed, and the mouth is completely closed. It is equally unable to burrow, and usually lies on the surface of the mud. Two tufts of silvery and usually lies on the surface of the mud. I wo ture of slivery respiratory filaments project from the fore-end of the body just behind the future head, and these wave to and from the water. as the animal alternately flexes and extends its body. At the iail end are two flaps, fringed with stout bristles, which form a iail end are two flaps, fringed with stout braitles, which form a kind of fan. The pupa virtually consists of the body of the fly, inclosed within a transparent kin. The organs of the fly are very closely resemble those of the perfect animal. These parts are, however, as yet very imperfectly displayed. The wings and legs are folded up along the sides of the body, and are and legs are folded up along the sides of the body, and are ineapable of independent movement. For two or three days ally had the blood-red colour of the larva, gradially assumes a darker tint. The tracked system, which was quite rudimentary in the larva, but is now greatly enlarged, becomes filled with an accessed from the star by the help of the respiratory tiths, are secreted from the star by the help of the respiratory tiths, splits, the fly extractes its limbs and other appendages, pause of a moment upon the floating purps.ceas, as if to fyr its wings, and then flies away.

This fly is a common object on our window panes, and would the first of Chronomus associate in swears, which are believed in the first of Chronomus associate in several ways. in this case to consist entirely of males. The male fly has plumed antenne with dilated basal loints. In the female fly the antennse are smaller and simpler, as well as more widely

segarated and herely stream another Dipterous have may often. In head and herely stream another Dipterous have may often the head of Simulium, known in the winged state as the smod-fly. The Simulium larve much smaller than that of Chinomonia, and its blood is not tinged with red. The head is provided with a pair of ciliary and here upon a sort of stem. The finged filaments are used to sweep the food into the mouth. The larve of Simulium subsums starticy upon microcopop plants and anomain. Among subsiss entirely upon microscopic plants and animals
these are great numbers of Diatoms, and the stomach is usually
found half full of the finity valves of these microscopic plants.
The Simulium larva seeks its food in rapid currents of water,
and a brisk flow of well-acrated water has apparently become a necessity to it. If the larve are taken out of a stream and placed in a vessel of clear water, they soon become sluggish, and in warm weather do not survive very long. It matters little, however, to the larve whether the water in which they live is pure or impure; and streams which are contaminated live is pure or impure; and streams which are contammated with sewage often contain them an great abundance. There are no externally visible organs of respiration, but the akin is supplied by an abundant network of the itraches blanches, which, no doubt, take up oxygen from the well-acrated water in which the animal lives. From this network at the surface, branches pass to supply all the internal organs. The Simulton larva is found upon aquatic weeds, and the pair of hind feet, which in found upon square weeds, and the pair of hind feet, which in Chinomona were shaped to as to enable the larva to hold on to its burrow, here become altered, so as to firmth a new means. The two obstares of hooks found in the Chinomonas larva form now a circular coroner, and the centre of the inclosed space becomes capable of being retracted by means of united swhich shape to the most of the contract of the inclosed space, which is, no doubt, aided by the citized of shap hooks. Efficient as this adherite organ andoubtedly n, it must be liable to de-rangement by occusional accidents, as, for instance, if there energement by occusional accidents, as, for instance, if there should be a sudden rush of water of unusual violence, or if the larva should be obliged to quit its hold in order to avoid some dangerous enemy. In the case of such an accident it is not larva should be colleged to quat its note in over to avoids some diagnetous enemy. In the case of such an accident it is not easy to see how it will ever recover it footing. Swept along in a rayed current, we might suppose that there would be but a stender probability of its ever finding itself favourably placed genies have been carefully proched for. The shirtway glants, or silk-organs, which the Chinonomic larva uses in weaving the sile of the sile of the shirt of th wall of its burrow, furnish to the Simulium larva long mooringthreads, by means of which it is anchored to the leaf upon which it lives. Even if the larva is dislodged, it is not swept far by the stream, and can haul itself in along the mooring thread in the

stream, and can haul issell in along the mooring thread in the same way that a spider or a Geometer larva climbs up the thread by which, when alarmed, it descended to the ground When the time for pupation comes, special provision has to be made for the peculiar circumstances in which the whole of the aquants life of the Simulum to passed. An inactive and exposed pupa, like that of Chironomus, may fare well chough on the soft muddy bottom of a slow stream, but such a pupa Simuluin is most at home. When the time of pupation draws Simulatin is most at home. When the time of pupation draws near, the insect constructs for itself a kind of nest, not unlike in near, the insect constructs for itself a kind of near, not unlike in shape the nest of some swallows. This nest is glued fast to the surface of a water weed. The salivary glands, which furnished the mooring-threads, supply the material of which the nest is composed. Sheltered within this smooth and tapering case, whose pointed tip is directed up stream, while the open mouth is thined down stream, the punk rests securely during the time

of its transformation.

When the pupa case is first formed, it is completely closed and egg-shaped, but, when the insect has east the larval skin, one end of the case is knocked off, and the pupa now thrusts one end of the case is knocked off, and the pups now thrests of the control of the case is knocked off, and the pups now thrests of the control of the contr the fore part of its hody into the current of water. The respiracocoon

The larva of the gnat is perhaps more familiar to naturalists of all kinds than any other aquatic Dipterous insect. interesting description, and, above all, the admirable engravings, of Swammerdam, now more than two hundred years old, are familiar to every student of Nature.

familiar to every student of Nature.

The larva, when at rest, floats at the surface of stagnant water. Its head, which is provided with vibratile organs suit able for sweeping minute particles into the mouth, is directed downwards, and, when examined by a lensi in a good light, appears to be bordered below by a gleaning bad. There are no thoncic limbs Theind-limbs, which were long and hooked in the burrowing Chrinomusi larva, and reduced to a bookin the burrowing Christonomus larva, and restaced to a Boos-bearing sucker in Simulium, now distappear allogether. A new and peculiar organ is developed from the eighth segment of the abdomen. This is a cylindrical respiratory sphon, reaversel by two large air-tubes, which are continued along the entire length of the body, and upply every per with air. The larva cordi-arily rests in such a position that the tip of the respiratory sphon is find with the surface of the water, and, thus say aphon is flash with the surface of the water, and, thus use pended, if each measurily, therething uninterrupedly at the product, if each increasanty, therething uninterrupedly at the migration of an increase and the product of the

savancing tail foremost. When it reaches the top, it hangs as before, head downwards, and resumes its feeding-operations. In order to explain bow the larve hangs from the surface against gravity, I must trouble you with some account of the properties of the surface-film of water. You will readily believe

that I have nothing new to communicate on this subject, and I that I have nothing new to communicate on this support, which wenture to show you a few very simple experiments, merely because they are essential to the comprehension of what takes

place in the gnat. in any reased of pure water, the particles at the surface, though not differing in composition from those beneath, are nevertheless in a peculiar state. I will not travel so far from the region of natural history as to offer any theoretical explanation of this of natural history as to ofter any theoretical explanation of this state, but will merely show you experimentally that there is a surface film which results the passage of a solid body from beneath. [Meabraugghe's float shown] You see (1) that the float is sufficiently lawyant to rice well out of the water, (2) that, when forcibly submerged, it rises with case through the water as far as the surface film. (3) that it is detained by the surface than the surface film. film, and cannot penetrate it. The wire pulls at the surfacehim, and cannot penetrate it. The wire pulls at the autrace-film and distorts it, but is unable to free itself. In the same way the surface-film re-ists the passage of a solid body which attempts to penetrate it from above. This will be readily seen if we throw a loop of aluminium wire upon the surface of water [Experiment shown] The loop of wire floats about like a stick of wood Aluminium is, of course, much lighter than iron, but the floating of this little bar does not mean that it has a lower density than that of water. If the bar is once wetted, it sinks to the bottom and remains there Even a needle may, with a little care, be made to float upon the surface of perfectly pure water. Still more readily can a piece of metallic game be made to float on water. [Experiment shown]. Air pass through the metales with no visible obstruction. But the pass through the metales with no visible obstruction. But the varies flim, bounding the air and water, is entirely unable to invoice even meales of appreciable size. These simple exper-ience of the properties of the prope of perfectly pure water Still more readily can a piece of metallic were unknown

We may now try to answer three questions about the larva of

the gnat, viz .- (1) How is it able to break the surface film when it swims upwards? (2) How is it able to remain at the surface without muscular

effort, though denser than water? (3) How is it able to leave the surface quickly and easily when elermed?

The tip of the respiratory slohon is provided with three flaps. the let por the respiratory sipaon is province with three maps, to large and similar to one another, the third smaller and differently shaped. These flaps can be opened or closed by attached muscles. When open, they form a minute basin, which, though not completely closed, does not allow the surface film of water to enter. When closed, the air within the uphon is unable to escape At the time when the larva rises to the surface, the pointed ups of the flaps first meet the surface filin, and adhere to it. The attached muscles then separate the flaps, and in a moment the basin is expanded and filled with air. The surface-film is now pulling at the edges of the basin, and the pull is more than sufficient to counterbalance the greater density of the body of the larva, which accordingly hangs from the sur-face without effort. When the larva is alarmed, and wishes to

face without effort. When the larva is alarmed, and washes to descend, the values close, then tips are brought to a point, and the reasting pull of the surface-film is reduced to an unimportant mount. Larvage larves shown by the instern, let the property of the property of the larvage of th properties of the surface-film explain all the phenomenaice-film is unable to penetrate the fine spaces between the flaps for precisely the same reason that it is unable to pass through the meshes in a piece of gauze

After three or four moults the larva is ready for pupation. By

this time the organs of the future fly are almost complete formed, and the pupa assumes a strange shape, very unlike that of the larva.

At the head-end is a great rounded mass, which incloses the wings and legs of the fly, beside the compound eyes, the mouth-parts, and other organs of the head. At the tail-end is a pair

* A number of other experiments illustrating the properties of the surface-film of water, are described by Prof. Boys in his delightful book on "Sono

of flaps, which form an efficient swimming-fan. The body of the pups, like that of the larva, is abundantly supplied with air-tubes, and a communication with the outer air is still institutional, though an an entirely different way. The air-tubes no longer open towards the tail, as in the larva, but towards the bead, placed that is a position of rest the margins of the transposition of the placed that is a position of rest the margins of the transposit come flash with the surface of the water. Floating in this position, the paper remains still, to long as it is undustried, but if attacked by any of the predatory aimnals which abound in fresh waters, it is also for detected by the powerful swimming move-

ments of its fail in

Not that the descent is without its difficulties. The pupa is
not like the larva, denier than water, but buoyant. There are
not like the larva, denier than water, but buoyant. There are
the the pupal to be a superior of the larva the

If we take a solid body, capable of being wetted by water, and place it in water, the surface-film will udliere to the solid. If the solid is less dense than the water, it will float with part of life the solid is less dense than the water, it will float with part of flow for the water of the solid water of the solid water for solid is dense film will be formen upwards around the solid will be pulled than the water, the variance film sound the solid will be pulled with the water of the water floats with part of its surface in contact with at, and that weights are gradually added to it. The result will be that the variance of the water around the part of the water around the part of the water water water water floats with part of its surface in contact with a road water water floats with part of its surface in contact with a road water floats with part of its surface in contact with a road water floats with part of its surface water wa

have observed more than the closed tube, the slightly open tube, and then the suddlen change to a completely upon condition and then the suddlen change to a completely upon condition. Another Dipterons have described and admirably figured by Swammerdan is the larva. Of stratuony, a larva which, as the structure of the fly shows, belongs to an altogether different emodely connected with the grant in the systems of scollegists, the Stratuonya larva has learned the same lesson, and is equally self-structured and the structure of t

membrane, it might foot and breathe prefetely well, but but old office the service of the prefetely well and the foreign latel foot of the prefetel with the service of the service collapse and their points approach; the idde-branches are folded in and the beam is in a moment reduced to a pear-shaped body, filled with a globale of air, and reaching the surface of the water at the first but of danger, swamming through the water with swaying and looping movements, somewhat like those of Chrisomins. When the danger is past, it canes to straggle, and floats again to the surface. The pointed up of its tall-ringe the floating beam is revorted.

the floating basin is restored. The larva of Strationys is extremely elongate. The length of its body has evidently some relation to the mode of life of the larva, but none at all to that of the fly which is formed within it. The puper is so much smaller than the larva as to occupy only the fore-part of the space within the larval skin. The interval becomes filled with air, and during the pupal stage the animal floats at the surface within the emby larval skin.

Strateomy, both in its larval and pupal nates, floats at the surface of the water. The larva, can descend into the water when attacked, but the pupa is too buoyant, and too much commerced the control of the pupal too buoyant, and too much commerced the control of the pupal to the superior of the helpless pupa against its many encours. It is probable that many many the pupal to th

The larva and pupo of the Dipterous fly, Psychopters pshaloine, exhibits one interesting adaptation of the trached system to unusual conditions. This larva is found in muchly distribes, where the larva is found in muchly distribes, where the larva is found in muchly distribes, where the larva is considered to the larva from the larva

Two trachesi trunks run along the whole length of the body, moduling the island rul, where they are extremely convoluted and uniterached. Towards the middle of the body the traches evening portions, from which many branches are given off, being comparatively narrow. Each tube, therefore, resembles a you of bladders connected by small needs a A cross-section shows that the tubes are not sylundruct, but flastened, and the theorem of the contraction of the contraction of the state of the contraction of the state of the state of the contraction of the state of the state of the contraction of the con

³ So singular is the disproportion between the larva and the pupa that some naturalists have actually described the latter as a paramie (Westwood's "Mod Classification of Insects," vol is p 530.

that the buoyancy of the larva can thus be regulated, and a larger or smaller quantity of art taken in a steined. The pape has a pair of respiratory tubes, which are carried, not on the tail, but on the thorax, close behind the head. One of these tubes is very long, the other very short. The long tubes is twice a long as the body, and tapes very gradually to its free tip Here we find a curious radiate structure, rather like the teeth of a moss capsule, which seems adapted for opening and closing. There is, however, no orifice which the most care-ful scrutiny has succeeded in discovering. A delicate membrane extends between the teeth, and prevents any passage inwards or outwards of air in mass. The tube incloses a large trachea, the continuation of one of the main tracheal trunks. This is stiffened by a spiral coil, but at intervals we find the coil deficient, while the wall of the tube swells out into a thin bladder occen, while the wall of the tube swells out into a thin bladder. However the tube is turned, a number of these bladders come to the surface. As the pupa lies on the surface of the mud, the filament floats on the top of the water, and the air is renewed without effort through the thin-walled bladders.

Why should the position of the respiratory organs be changed from the tail-end in the larva to the head-end in the pupa? from the tail-end in the larva to the head-end in the papira? Chronomus, the gnat, Coretina, and many other aquation is seets exhibit the same phenomenon. Evidently there must be some reason why it is more convenient for the larva to take in air by the tail, and for the pupa to take in air by the head. Let us consider the case of the larva first. Where it floats from the surface, or pushes some part of its body to the surface, it is plain that the tail must come to the top and bear the respiratory outlet, for the head bears the mouth and mouth-organs, and must sweep to and fro in all directions, or even bury itself in the mud in quest of food To divide the work of preathing and feeding between the opposite ends of the body is of obvious advantage. for the breathing can be done best at the top of the water, and the feeding at the bottom, or at least beneath the surface Such considerations seem to have fixed the respiratory organs at the tail of the larva Why, then, need this arrangement be reversed when the insect enters the pupal stage? There is now no feed when the insect enters the pupal stage? There is now no feeding to be done, and it startly does not signify how the head is upon the pupal stage. It is not startly a startly as startly a startly a startly as startly a startly as startl transport to the second of the plan institute to concerned, any good trute. But at time ones when the fly has to except from the pape case. The skin splits along the back of the thorax, and hee the fly menger, extracting its legs, winey, head, and must be drawn backwards out of their farval sheaths, the legs upwards, and the sholmen forwards, to that there it only one possible place of escape, me by the back of the thorax, when the cacape by the back of the thorax, the the cacape by the back of the thorax, the back of the thorax must float uppermost during at least the latter part of the pupul single the second of the control of the second of the control of

I need hardly speak of the many insects which run and skate on the surface of the water in consequence of the precluiar properties of the surface-time. They are able to do so, first, by other times of the surface of I need hardly speak of the many insects which run and skate

In the case of very small insects, it becomes possible, not only In the case of very small macets, it Decomes possible, not only to run on the surface of the water, but even to leap upon it, as upon a table. This is particularly well seen in one of the smallest and simplest of all insects—the little black Podura, which abounds in sheets of still water The minute and hairy body of the Podura is incapable of being wetted, and the Insect body of the Fodura is incapable of being wetted, and the insect files about on the silvery surface of a pond, just as a house fly might do on the surface of quicksilver. This is all very well so long as the Fodura is anxious only to amuse itself, or move from place to place, but it has to seek its food in the-water, and, indeed, the attractiveness of a sheet of water to the Fodura lies mainly in the decaying vegetation far below the surface But if the maset is thus incapable of sinking below the surface, how

does it ever get access to its submerged food? I have endea-voured to arrive at the explanation of this difficulty by observa-tion of Poduras in captivity I flow place a number of Poduras in a beaker half full of water, they are wholly unable to sink in a lieaker half full of water, they are wholly unable to sink They run about and leap upon the surface, as if trying to escape from their prison, but sink they earnot 1 have chased their about with a small rod until they became excited and much about with a small rod until they became excited and much large quantities of alsohol were added to the water, the dead bodies of the Podura are seen froating at the top, almost a set ies of the Podura are seen floating at the top, almost as dry as before. It is only when they are placed upon the surface of strong alcohol that the dead hottes become wetted, and after a considerable time are seen to sink. How, then, does the Poduia ever descend to the depths where its food is found?

Podua ever descend to the depths where its food is found?

I found it an easy matter to make a ladder, by which the Poduze could leave the upper air. A few plants of duck weed introduced into the beaker enabled them at pleasure to pull theuselves forcibly through the surface film, and climb down the long root banging into the water like a rope. Once below the surface, the Podura, though buoyant, is enabled, by muscular exertion, to swim downwards to any depth

Other aquatic insects, not quite so minute as the Podura, experience something of the same difficulty. A Gyrinus, or a small Hydrophilus, finds it no easy matter to quit the surface of the water, and is glad of a stead or root to descend by

To leave our aquatic insects for a moment, we may notice the habit of creeping on the under side of the surface-film, which is so often practised by leeches, snails, cyclas, &c 1 find this is often described as creeping on the air, and some naturalists of the greatest eminence, speak of fresh-water snalls as creeping "on the stratum of air in contact with the surface of the water." "on the stratum of art in contact with the surface of the water".

The body of the animal is, nevertheless, wholly immersed during this exercise, as may be shown by a simple experiment. If I youngodium powder is sprinkled over the water, the light particles are not displaced by the animal as it travels be particles are not displaced by the animal as it travels be maint. The possibility of creeping in this manner depends, of the body, "to quote an explanation which is often given, but upon the tennesty of the surface fails, when severe as a kind of coling to the water-chamber below. The body of the feech is coling to the water-chamber below. The body of the feech is quality to the bottom, if the animal loses it the lost of the surface-film. The pond snaits, however, actually float at the surface-ant I dausted, or made to retract their foot, they precely nurn ow r in the water

owe in the water. What is the result of all the expedients which have enabled air breathing insects to overcome the difficulties of living in water? They have been successful, we might almost say too successful, in gaining access to a new and ample store of food. Aquatic plants, minute animals, and dead organic matter of all kinds abound in our fresh waters. Accordingly the species of aquatic insects have multiplied exceedingly, and the number of adjustic insects have indusprise executingly, and the number of individuals in a species is sometimes surprisingly high. The supply of food thus opened out is not only ample, but in many cases very easy to appropriate. Accordingly the head of the have degenerates, becomes small and of simple structure, and may be in extreme cases reduced to a mere shell, not inclosing the brain, and devoid of eyes, antenne, and jaw. The organs of locomotion also commonly afford some indications of degeneration. Where the insect has to find a mate, and discover generation where the insect in as to find a mate, and curvover suitable sites for egg-laying, the fly at least must pos-ess some degree of intelligence, keen senve organs, and means of rapid locomotion. But some few aquatic in-eets, as well as some non-aquatic species which have found out an unlimited store of food, aquatic species which have found out an untimited store of food, manage to produce offspring from unfertilized eggs, and to have these eggs lard by wingless pupe or hatched within the loodies of wingless larvæ. The development of the winged fly, the whole business of mating, and even the development of the embryo within the egg, have thus, in particular insects, been abreviated to the point of 'ppression' This is what I mean by saying that the pursuit of a new supply of food has in the case of certain aquatic insects proved even too successful. Abundant

cerain square insects proved even too successful. Abundant food, seeding no exertion to discover or appropriate it, has led in a few instances to the almost complete atrophy of those higher organs and fauctions which alone make life interesting. The degeneration of aquatic insects, however, very rarely reaches this extreme. In nearly all cases the pupe is succeeded by a fly, whose activity is in striking contrast to the sluggaliness.

Semper's "Animal Life," Eng tram , p 205, and note 97

of the laws. They differ, to the eye at least, almost as much as air differ from water.

Of the frends to when the state of the laws to be a consumer to the state of the stat

American Journal of Science, September —On the capture of councts by planets, especially their capture by Jupiter, by H A Newton The full paper is not now given The completed results will be noted in Our Astronomical Column as soon as they are published —Pleistocene fluvial planes of Western Pennsylvania, by Frank Leverett Some facts are stated which clash with certain conclusions drawn by Mr P Max Foshay in a paper entitled "Pre-Glacial Drainage and Recent Geological History of Western Pennsylvania," which appeared in the November number of the Journal From these appared in the November number of the Fournial From these it appears that the obsades to a northward discharge of the Sheanago, Mahoung, and Beaver are, on the whole, greater than those in the way of a southward discharge in the Monongahela, Lower Alleghany, and the Ohio valleys, the available evidence all indicates southward discharge along the present course of the Ohio from the inter-Glacial period to the present time -A method for the determination of antimony and piecent time —A method for the determination of antimony and its conditions of oxidation, by F. A. Gooch and H. W. Griener —A method for the estimation of chlorates, by F. A. Gooch and G. S. Smith —Dampening of electrical oxidiations on iron wire, by John Trowbridge. The experiments lead to the consecution of the control of the control of the consecution of the control oxidiations of high frequency. This influence is so great oxidiations of high frequency. This influence is so great with the oxidiations may be reduced to a half-calculation on a circuit of suitable self-induction and capacity for profusing them. be changed. Only a half-oscillation has been obtained on iron wires, so this law cannot be stated definitely - (3) Currents of high frequency, such as are produced in Leyden jar discharges, therefore magnetize the iron —Genesis of iron ores by isomorphous and pseudomorphous replacement of limestone, &c., by James P Kimball. The author adduces a considerable amount of evidence showing that such products of epigenesis as amount of evidence snowing that said products of direct pseudo-morphous replacement of isomorphous calcu carbonate, like himestone, calcute, calcusinter, calcareous sediments, &c. And hméxtone, calcite, calc-miter, calcineous secliments, &c. And the general proposition is therefore advanced that deposits of concentrated iron ores occur far more extensively as pseudomorbon suplacements than is usually supposed—On the constitution of the constituti

gravels are of the pre-Pleistocene age —Note on the causes of the variations of the magnetic needle, by Prof Frank H Bigelow (See Our Astronomical Column)—Notice of new vertehrate fossils, by O. C. March

THE American Meteorological Journal for August contains the following articles —Mountain meteorology, by A. L. Rotch. The author points out the advantages of mountain stations at which regular and continuous observations can be made as com-pared with fragmentary observations in halloons. The chief characteristic of the pressure at high altitudes in temperate and pressure in winter, thus the barometer varies inversely at high and low levels. With elevation above the sea, the absorption of aqueous vapour diminishes, or inversely, solar radiation in creases. In the Himalayas a black hulb thermometer in vacuo hade lennerature was only 75. In general, the annual range shade lemperature was only 75. In general, the annual range of temperature diminishes with height, so that at an elevation of about 39,000 feet, which is the height of the cirrus clouds, probably the temperature is constant throughout the year. The nygrometric conditions at high altitudes are subject to rapid accompanied by analogous thermal changes. In all mountainous ing into the valleys during the day, and out from the valleys during the night. On calin, clear, winter nights the air in the valleys is often colder than on the mountain slopes. The author meteorological science is due to the establishment of mountain stations, and that in comparing the work done by various nations to advance monniain meteorology, France stands un-rivalled. The German and Austran stations are frequently badly placed, being located in inns below the suminits Among the best stations (in addition to the French) he mentions the Sonnblick, Hoch Ohr, Santis, Ben Nevis, and Mount Washing ton—On the various kinds of gridients, by I. Lisserenc de Bort. This is a translation from the memoirs of the Meteorological Congress held at Paris in 1880, in connection with the International Exhibition The air being put in motion by dif-ferences of pressure, there ought evidently to be a relation hetween the gradient and the wind velocity, but although the wind increases with the gradient, there is no exact ratio, nor a constant relation from day to day. The author reviews the subject in connection with changes produced by temperature and dynamic effects upon the rectifinear movements of the atmodynamic effects upon the restributes movements of the atmosphere, and the movements caused by the carth's rotation, and sphere, and the movements caused by the carth's rotation, and of the supermounded layers, the effect of which ought to be revised by the post-ration—The clumate history of Lake Bonneville, by R de C Ward. This is an abstract of a monograph by J & Gilbert, published by the United States Geological Survey. The paper is chiefly geological, but has an important bearing upon the secular changes in climate Lake Bonneville was the upon the secular changes in climate ancestor of the great 'Silt Lake of Utah, which has frequently altered its level, even in recent years. At the time of the glacial attered its fevel, even in recent years. At the time of the gindeal epoch its level was about 300 metres higher, and it occupied about ten times it yessent area. The cause of the drying up of a large part of the former area is found in the prevailing winds which, on their way from the Pacific and in their passage over the Siera Nevaids, have precipitated much of their moustower. ture, and pass over this region as drying winds —The other articles are observations at a distance (by means of electricity), by T. P. Hall, ocean fog (the causes which produce it), by E. Carriott, and water spouts (observed on a voyage), by Prof C. Abbe

ANIMAL CHLOROPHYLL

Die Organisation der Turbellaria Acala Von Dr Ludwig von Graff. (Engelmann, 1801)

LIGHT years ago Dr. von Graff published his great monograph of the Rhabdocel Turbellarians. The improved methods of histological research have enabled him to add some essential facts since that date to our knowledge of one of the most curious groups of the Rhabdoccila-amnely, those known as Accela In 1885, he passed his Easter holidays at the Franciscan convent on the Dalmatic island of Leana, and on the sea-shore of the garden of the convent found Convoluta Schultzu and canera in abundance.

Prof Delage in 1886 published his valuable researches on Comoluta Roscoffents, the green species of Roscoff, in which he made use of a method of gold-impregnation for demonstrating the nervois system Dr. von Graff visited Roscoff in the same year, and in 1889 studied the Accila at the Naples Station by ineans of Delagés and other methods of gold-impregnation. The present volume deals with Propriets viences, O. Schim, Nompopous vientrymutatus, O. Schim; Afphanostoma diversioler, Oerst, and several species of Convoluta, 1 their ghown amongst other facts that the Roscoff species studied by Geddes and Delage is distinct from the Mediterranean C. Schultzus, and that C. unrea, Graff, must be placed in a new genus, Amphacharus.

The work is illustrated by ten quarto plates, coloured A variety of important anatomical and histological details are given, and a systematic discussion of genera and species Dr. von Cariff discusses the relationship of Truloplar to the Accela, having received living specimens of this curious form from the aquarium of the Coological Institute of Vienna, but he does not allude to the Holpdains piger of Weldon (Quarterly Tournal of Microscopical Scenez, vol xxx), a floating form, taken off the Bahamas, which seems to be certainly a member of the group.

The chief matter of interest in Dr. von Graff's volume. which we propose to notice at greater length, is the chapter by Dr. G. Haberlandt, on "the structure and significance of the chlorophyll-cells of Convoluta Roscoffensis" Dr. Haberlandt states that the description by Geddes of the chlorophyll of this form, as diffused in the general plasma-body of certain cells, is erroneous The green-coloured cells he well below the cuticle, embedded amongst the cells of the superficial parenchyma According to Haberlandt they are highly compressible and elastic. and devoid of anything like a cellulose envelope or even a membranous envelope. They are not uniformly green, but there is as a rule a single large chloroplast which forms a more or less complete shell to the protoplasm of the cell-body. In some of the cells Haberlandt could detect several peripheral plate-like chloroplasts. The crust-like chloroplast contains as a rule a single centrally placed pyrenoid of spherical form. As an exception two or even three pyrenoids are present. The pyrehoid is colourless: it is stained by hæmatoxylin or by borax carmine, but by no means so strongly as is the nucleus of

the cell in which the chloroplast occurs. Starch granules in the form of small curved rods are grouped around the pyrenoid (sometimes within it), and are detected by a violet-invon reaction on addition of sodine solution. The colouries protoplasm of the cell is small in amount as a compared with the enveloping chloroplast: its nucleus is studied in the colouries protoplasm only rendered visible by staming. The colouries protoplasm sometimes contains a group of granules of doubful nature, erroneously taken by Geddes for starch granules.

The resemblance of these cells, especially in respect of the stincture of their chloroplasts and pyrenously, to certain cells which constitute the uncellular bodies of Volvocinea, Tetrasporea, and Pleumococacaca, is insisted upon to by Haberlandt. He raises the question as to whether they are to be regarded as passitic Alge in the sense of the theory of Entr and Brandt, and suggests another hypothesis—manley, that, withis phylogenetically they must be regarded as Alge (that is to say, have descended from Alga), by at the present time they have by profound adaptation to life in and with the Convoluta, allowing gether lost their character as independent algal organisms, and have become an integral histological element of the worm, and in fact constitute its assimilation time.

To test this hypothesis he asks (1) How do the green cells get into the body of the worm? and (2) What becomes of them when the worm dies? Can they live in an isolated condition? To the first question he is unable to give an answer, but suggests that they may be handed on from generation to generation of the Convoluta, entering the egg-cell as a colourless minute cell which later develops its chloroplast just as the "leucoplasts" of higher plants are found in the egg-cell, and later become chloroplasts As to the second question, Haberlandt has no doubt. The green cells die when they are removed from the worm's body or when the worm dies He notes in this connection their membraneless character, and regards the loss of a cellulose envelope as one of the modifications which the ancestral parasitic Alga has undergone, rendering it incapable of living an independent life away from the tissues of its host Lastly, Haberlandt justly remarks that similarity to an Alga is no proof that the green cells are really Algæ in nature Haberlandt is inclined to place his theory as to the green cells of Convoluta alongside the suggestion of Schimper as to the origin of the chlorophyll corpuscles of higher plants-namely, that these are due to the union in the remote past of a green-coloured with a colourless organism. In this case and in that of Convoluta the highest phase of symbiotic association is attained, for the green organism can no longer be separated and cultivated apart, as in the case of the Lichens, but has, in fact, become an organ of the colourless organism, multiplying with it and forming an integral as well as a necessary part of its mechanism, and so greatly modified by ages of association as to be now barely recognizable as derived from an independent source. We can well suppose it possible that the green cells of Convoluta might proceed further in their modification, so as to lose the colourless protoplasm and the cell-nucleus; they would then become simple chlorophyll corpuscles like those of higher green plants.

The suggestion thus put forward by Haberlandt is in

complete accord with the view which I have several times expressed in regard to the chlorophyll corpuscies of Hydra viridis and of Spongilla viridis (see Quart Journ. Micr. Sa., vol. xxii p. 229), viz that there is no more reason for regarding them as symbiotic Algae than there is for so regarding the chlorophyll-corpuscles of a buttercup. Whether there is sufficient reason for so regarding the chlorophyll-corpuscles of a buttercup is another question, and one which certainly is not yet decided in the affirmative, though there are considerations which render such a hypothesis one not lightly to be dismissed.

A difficulty in the matter seems to be this-viz that if the chloroplasts of the cells of multicellular organisms are to be regarded as parasitic, why should not those of unicellular Algae also be regarded as parasitic? and if "Zoochlorella," or whatever the hypothetic Alga may be called in the case of Convoluta, can form chloroplasts, why should not the tissue-cells of Convoluta themselves, or of Hydra,

or of Spongilla form chloroplasts?

It is obviously necessary to distinguish for the present (though posubly, as Haberlandt suggests, the one may be derived from the other) the strongly-marked unicellular parasites of Radiolaria and Anthozoa (the "vellow cells") from the green cells of Convoluta, and the chloroplasts of Hydra viridis, of Spongilla fluviatilis, and of many Ciliata. The statement which is current as to the existence of a nucleus in the chloroplasts of Hydra is simply erroneous, and that as to the independent multiplication of the chloroplasts of Ciliate Infusoria when removed from the cell in which they occur is possibly a misinterpretation of a graft-phenomenon. It is to be hoped that Dr Haberlandt will spare the time to study for himselfas he has the green cells of Convoluta-the more readily obtainable chloroplasts of Hydra, Spongilla, and Stentor

Some extremely interesting and suggestive remarks on the physiological and biological phenomena connected with the green cells of Convoluta conclude Dr Haberlandt's chapter E RAY LANKESIER.

STREATFEILD'S PRACTICAL ORGANIC CHEMISTRY

Practical Work in Organic Chemistry By Fredk Wm. Streatfeild, FIC, &c., Demonstrator of Chemistry at the City and Guilds of London Institute's Technical College, Finsbury With a Prefatory Notice by Prof. R Meldola, F.R.S "Finsbury Technical Manuals" (London, E and F N Spon, 1891)

HE numerous manuals of practical organic chemistry which have been published of late years testify to a re-awakened interest in an important subject. Some of these deal with the preparation of various typical organic compounds, others restrict themselves to describing methods of analysis. The present work combines both methods of teaching, and, as a special feature, divides the subject into "programmes of instruction" designed to meet the varied wants of the students attending the evening classes of chemical technology at the Finsbury College, taking into account the special nature of their daily avocations and the purpose to which they

wish to apply their chemistry. Thus, after working through the introductory courses of "operations" and "analysis," and thus familiarizing himself with the general methods of the subject, the student would begin to specialize The brewer would select the programme "ethyl alcohol and its reactions," which includes fermentation and the purification and estimation of alcohol. and touches on allied subjects, such as the preparation of aldehyde, acetic acid, and chloroform The soap-maker would devote himself to the programme, "a study of the preparation and decomposition of ethyl acetate, and of the composition and reactions of some of the natural fats and oils"; thus passing from the simplest case of saponification (hydrolysis) of an ethereal salt in ethylacetate to the more complex cases in the fats. This latter programme also includes the isolation and estimation of glycerol, and its properties; palmitic, stearic, oleic, and elaidic acids, drying and non-drying oils, bromine and iodine absorption of oils, and other matters of interest in this connection. The tar-distiller would carry out the experiments given under "coal tar and coal-tar products"-a very full and satisfactory chapter

This restriction of the field of study is amply justified by the necessities of the case, and only an irreclaimable scientific purist would object to it. Even the ordinary day-student of chemistry, who can devote his whole time and energies to the subject, must work under some similar limitation when he comes to deal with the mexhaustible material of organic chemistry

The experiments given under the various programmes are well selected, and the accompanying descriptions are evidently the outcome of a thorough practical knowledge of the subject. We may make an exception, however, in the case of the preparation of anhydrous formic acid (p. 66) by passing sulphuretted hydrogen over dry copper formate The method is quite obsolete: Lorin's improved process of preparing the pure acid from anhydrous glycerol and anhydrous oxalic acid, drying the 95-98 per cent acid thus obtained with boric aphydride, is now employed Worst of all, the author recommends in this experiment that the sulphuretted hydrogen should be dried by passing it through concentrated sulphuric acid -a blunder which would go far to justify the prevailing impression that organic chemists are not always sufficiently conversant with the facts of inorganic chemistry

In spite of this and one or two other trifling inaccuracies, we cordially recommend the book as a valuable aid to both teacher and student. What it deals with really is practical organic chemistry, and not the spurious substitute which, in the shape of "the detection of not more than one organic acid and one organic base," usurps the name in this country-thanks to the authority of examining boards, the industry of the writers of cram-books, and the credulity of the public.

Prof. Meldola, in his prefatory notice, referring to the evening classes in chemistry at the Finsbury College, says that they "cater for no examination"; and it is perhaps owing to this important circumstance that Mr. Streatfeild, on whom a considerable share of the laboratory teaching of these classes devolves, has been in a position to write a real manual of practical organic chemistry, and not a mere cram-book of tests-written up to syllabus.

TELESCOPIC WORK

Telescopic Work for Startlight Evenings By W F Denning, F.R A.S (London: Taylor and Francis, 1891)

A S might be expected from such an experienced and enthusiastic observer as Mr Denning, this book is thoroughly practical. He is not contented with describing the beauties of the skies, but gives invaluable information as to how to see them best The opening chapters give a very complete history of the invention and development of the powers of the telescope and its acces-These are followed by chapters on the sun. moon, planets, stars, nebulæ, and clusters, the sun being introduced for the sake of completeness, although not comprehended in the title. The question of the relative advantages of large and small telescopes is discussed at considerable length, and one almost gets the impression that large telescopes, except under very favourable conditions, are not desirable possessions. It is very gratifying to note the encouragement given to observers of limited means. To them the book will be of the greatest assist-

ance, both in the selection and use of their instruments. The author's style is such as to make the book very entertaining as well as instructive. Some of his remarks are well worth quoting, as, for example, his opinion of controversy in scientific matters.

"Competition and rivalry in good spirit increase enhusiasam, but there is little occasion for the bitterness and spleen sometimes exhibited in scientific pournals. There are some men whose reputations do not rest upon good or original work performed by themselves, but rather upon the alacrity with which they discover greevances, and upon the care they will bestow in exposing riting errors in the writings of their not-infallable contributions of the contribution of the contribution

Mr. Denning is very emphatic in his opinion that an observer's time is too valuable to be spent in acting the showman to his friends and acquaintances. If all observers were so disposed, there might be reasonable hope for the establishment in this country of some such institution as the Gesellschaft Urania in Berlin, for the special gratification of persons desiring passing glumpses of celestial wonders.

It is scarcely necessary to say that the chapter on meteoric observations is as good as can be More observers are undoubtedly needed in this branch of astronomy, and volunteers will find every full instructions in the pages of this book. In addition to the notes on variable stars given by the author, we would suggest the tracing of the light-curves of a small number of stars by each observer. Anyone at present attempting to determine the laws governing variability will find such information lamentably deficient.

The book is full of important practical details, and an appendix gives the chief new facts up to March 5, 1891

The book does not attempt to deal with spectroscopic matters, but occasional references are made, and it is here; if anywhere, that fault may be found. Thus, referring to the nebula of Orion, it is stated (p. 334) that "the spectroscopic researches of Huggins have shown this nebula to be composed of incandescent gases, so

NO. 1142, VOL. 44]

that the stars telescopically observed in it are probably in the foreground and entirely disconnected from the nebulous mass."

In 1888, however, it was shown by the spectroscope that the stars of the trapezium, at all events, are simply condensations of the matter composing the nebula

Everyone who uses a telescope, or who intends to use one, of whatever dimensions, should read Mr Denning's book

OUR BOOK SHELF

Abbildungen zur Deutschen Flora H. Kursten's, nebst den auslandischen medicmischen Pflanzen und Erganzungen für das Studium der Morphologie und Systemkunde With Woodcuts of 709 Species (Berlin Friedlander und Sohn, 1801.)

FHIS is a wonderfully cheap book, for the price of it is only three marks, and it contains figures with dissections of upwards of 700 plants, illustrating all the natural orders both of Cryptogamic and Phinergamic plants which make up the European flora or are used medicinally The text is confined to the preliminary table of the orders and families, and a final to the preliminary table of the orders and families, and a final to the preliminary table of the orders and families, the second for the certain the preliminary table of the orders and families, and a final to the preliminary table of the orders and families, and a final to the preliminary table of the orders and families, and a final the preliminary table of the price of the pri

in the Thallophyte are divided into 17 families, classed under sorders, Lichenes being maintained as on a par with Alge and Fungi. In Cormophyte there are 16 families under 6 orders, the orders of Sporifiera being Filices, Selagines, Rhisocarpeæ, and Calamariæ In Northocarpe (Gymnosperns) there are 7 families under 5 orders, Balanophorace and Lorantheæ being placed here. Under Teleocarpe (Angosperns) there are 150 families classed under 48 orders, Luccipledons being divided mits Monochlamytees and Dichlamyties, and the latter into Petalantheæ (Polypetales) and Corollamine to International Control of the Corp. The Corp. (Polypetales) and Corollamine to Itembam and Hooker's orders. In lawe such a good and chasp book in English (the text in the original, of course, is German) would be a great boon to students

Elimentary Text-book of Botany for the Use of Schools By Edith Aitkin. 248 pp (London Longmans, Green, and Co., 1891)

This volume has been written to serve as an adjunct to the teaching of Botany in girls' schools, and is the outcome of the author's own experience as a teacher Aitkin arranges the subject-matter in three parts In the first are given the general characters of a number of tirst are given the general characters of a number of selected types of Flowering plants treated in a manner suitable for young girls beginning the study. In the second part the details of Cryptogamic plants are given, commencing with *Protococcus* and Yeast, and so on, up to the Fern. In the third part we return to Flowering plants again from a more comprehensive point of view. This last section concludes with a number of chapters on the leading physiological processes of plants We think the book will be found of service by those for whom it is intended, especially from the fact that Part I is written, generally speaking, on the lines of the Lower Schedule laid down by the Oxford and Cambridge Schools Exa-mination Board The only criticism we have to make on this section is that perhaps the style is a little wanting in vitality and interest. Part II is treated along sufficiently familiar knes, but in Part III., by the introduction of physiological work, with careful instructions as to simple experiments which can easily be performed to illustrate class teaching, we think that the author will have opened up fresh fields of interest in botanical study. The volume is profusely illustrated, many of the figures being new.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinions ex-pressed by his correspondents. Nather can he undertake to return, or to correspond with the winters of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications!

A New Mammal from Sumatra.

A FEW years ago a new and interesting mammal, which is exceedingly rare even in its native haunts, was brought to the then President of Plenthanga, PM. A Prays van der Hoeven. This gentleman, who is not only an eager sportsman, but also well versed in natural history, recognized it to be new to science, and to be more closely allied to certain representatives of the Edentiat than to any other order of mammals.

The type-specimen was preserved in captivity for several weeks, was fed on ants, and afterwards on cooked rice, and was weeks, was led on ante, and atterwards on cooker free, and was sent alive to Europe in order to be examined, described, and ultimately preserved in the Royal Museum at Leyden It unfortunately died on board the vessel on its way to Holland, and, by an unaccountable blunder on the part of one of those in charge, its remains were not preserved, but thrown overcharge, tis remains were not preserved, but thrown overhonni

During my own stay in Sumatra, from February till May 1891, I took particular trouble to obtain further information concern-ing this animal, and have found the fact of its existence—though, ing this salmal, and have found the fact of the easternes—though, at the same time, of the exceeding ranty—confirmed in a way which does not allow me to doubt that, ere long, further specimens will be swallbel for a through estimation, also with example the salman of the salman of the second specimen have not as yet been successful, but as they have drawn the attention of many persons to this animal, I feel bound, in deference to the claims to priority of its original. I feel bound, an deference to the claims to priority of its original accoverer, who has put he preliminary description as well as manimal into science, notwithstanding the fact that the type-specimen has been lost. The generic name has been elected, not with a view of indicating any clearer nationneal relations of the salman of the salman

Trichomanis Hoevenis, gen et sp. nov - "Animal of the size of a very large cat. Fur grey, with a black longitudinal band along the middle of the back. Snout elongated and more or along the middle of the back. Shout elongsted and more or less conical, with a small month at the extremity. A long less conical, with a small month at the extremity. A long collection of ants, which are its natural food. A more or less bushy tail. Ears not conspicuous Legs higher than those of Manus, strong claws to the feet."

I have no doubt that this description—however superficial—

is more than sufficient for the recognition of the animal as soon as it will have been reobtained. The type-specimen was caught in the mountainous districts that separate the Residencies of Palembang and Bencoolen in Sumaira.

An Ovlparous Species of Peripatus

Perspatus leuckartus has proved to be by no means une in Victoria, being now recorded from a good many distinct localities, and forming a very characteristic constituent of our cryptoroic fanns. Hitherio, however, little has been known of its habits, and nothing of its mode of reproduction. The only tis labits, and anolong of its mode of reproduction. The only to lonerers, to fir at I am aware, who has recorded anything concerning tis life heteroy, as Mr Fletcher, who has described (Frocellum, Soc N SW, Qeother 31, 1885) four very young individual to the control of the c

of the jar on two thin slips of glass, so as to admit of free ventilation I keep a small open jar fall of water inside the large one, and the floor of the vivarium is covered with a thick layer of very rotten wood, kept molat by the evaporation of

isyer of very rotten wood, kept most by the ewportation of the water the conditions Propagation flourness well, and the specimens may be inspected when desired, by turning over the bits of rotten wood. On making such an inspection to day, I found that some twelve or fifteen eggs had been deposited beneath some of the pieces of rotten wood, and in crevices of the same Carefal examination showed that these eggs were modobitedly those of Propagation fluxering. I collected all I could find, and removed them, with some of the rotten wood, to a separate receptacle, and then carefully turned out the vivarium and examined its contents I found that there were present four specimens of Perspains, one male and three females, all apspeciment of respents, one make and time tensions, at ap-parently in good health, and that there was nothing else which could have laid the eggs, a very small ant being about the largest living thing present except the Portpatus It is now some ten weeks since the vivarium was stocked, and as I have carefully examined it several times during that period, I am sure that the eggs must have been recently deposited.

The view that Peripatus Leuckas is is really oviparous receives

The wee that Perspitute Jacobs is a really overpareas receives trong confirmation from anatomical estamlation of adult females. In these I have nearly always found eggs in the uterus, but, although I have discreted speciment staken in December, May, and July, I have never found any embryos. The single end of the month and given to me by Prof. Specimer, it contained mether eggs nor embryos, as it appeared to be adult, it is not unlikely but the eggs that been land. Moreover, the structure of the eggs in utas is very characteristic, and argues strongly squared the probability of instituterine development, their, cleanter membrane inclosing a quantity of thick milky fluid full of yolk remains.

full of yolk granules

I have examined microscopically only one egg after laying, as I wish, if possible, to observe the development, but this one agrees so closely with those found in utero that there can be no doubt of its identity It was of just about the same shape and size ($\frac{2}{2\pi}$ inch long by $\frac{2}{2\pi}$ inch broad), of a very pale yellow colour, with a very tough, elastic membrane, and a milky fluid contents containing very many yolk granules The only difference concerns the almost chilinous looking membrane, which, ence concerns the aminost entitions toloning menutrates, whilest, mistead of having a smooth surface, or nearly so, as when in there, is exquisitely sculptured or embossed in a beautiful and regular design. The design consists of curious little papillar, somewhat resembling worm casts, arranged at fairly regular intervals over the surface of the egg, with much finer, close-sea, intervals over the surface of the egg, with much finer, close-sex, meandering rights occupying the pasce between them. Such exclipturing it, as is well known, characteristic of many interesting in a surface of the control of the co

double brooded (I have used the term "uterus" in accordance with the customary nomendature; it would be britter, perhaps, to speak only of "ordatus" in P lanckarits.)

The mode of reproduction of Perspitati includes its seem thus to differ welely from that known in all other speedes, and to differ welely from that known in all other speedes, and to quantity of food-polic present, it is probable that the development also drifters in a similar way. This i hope to be able to work out, the presence of so much full dand granular yolk will, I fear, render the task very difficult.

ARTHUR DENDY.

The Sun's Radiation of Heat.

A FEW months ago I sent to the National Review a paper, which the editors kindly inserted, on the sun's radiation of heat So far as I am aware, my theory has been completely ignored by those best competent to form an opinion upon the subject. My contention seems so plausible that I venture to suppeal to you to allow me to give the following brief exposition of my view, in the hope that I may be able to elicit some

of my view, in the hope that I may be able to elicit some authoritative replay radiation is at present, for all ments and purposes, expressed in terms of neiting ice. In other words, the sun is supposed to be giving forth as much heat as a constantly renewed shell of ice, or never-failing coans of water. My conception is, that, judging from what we know of hot bodies coling upon the earth, it is impossible to believe that the sun could be pouring forth so much heat under existing conditions, as the would do were he continually or radiate to ice or water close to all parts of his surface.

I ne veiocity, and the rapidity of vibration of the waves of light and heat can be accurately measured. This is the sum of motion—known as radiant heat—which the sun imparts to his surrounding medium. Alsorbed heat is a very different thing (Ballour Stewart), and could not exist without the particles of matter. Now I fall to perceive what grounds the authorities. have for calculating, as they do, that the sun's radiation amounts to something over a million calories per minute for each square metre of his surface. This means a million times the quantity of heat which will raise the temperature of a kilogramme of No doubt if the sun were surrounded b shove would represent a correct estimate of the outflow of heat But the men of science ignore, it appears to me, the marvellous virtue of the "if" in this case. The communication of heat consists in forcing the molecules and atoms of matter asunder against the stiractions of cohesion and affinity, and causing the against the stractions of cohesion and allinity, and causing the particles to wheate, and there is no proof, but the evidence is particled to the steer of the st more quickly than if it were merely exposed to a very dry atmo sphere—that is to say, the metal v rathers that would constitute a less expenditure of energy than its emission of absorbed heat I do not see, therefore, why we should not conclude that exactly the same result, only of course on a very vast time-scale, would happen in the case of the sun

The enormously long periods demanded for the sun's past

life-time by the geologist and biologist furnish strong ante-cedent support in favour of my contention W Goff New University Club, 5 W, August 15

Morley Memorial College

YOUR readers may be interested in hearing of a successful attempt to add another round to the ladder, described by Prof Iluxley, extending "from the gutter to the University" Some supporters of the Morley Memorial College for Working Men and Women, in the Waterloo Road, last year read an account and women, in the waterioo Roat, list year read an account in your pages of the arrangements made by the University Extension Society for some of its students to spend a month at Cambridge during the vacation. They resolved to offer scholarships to those who took the hext places in the Christians and Easter examinations in connection with Mr. McClure's astronomy Easter examinations in connection with Mr McClure's attronomy class, whereby they might avail themselves of these arrangements. This, thanks to Dr. Roberts's kind eo operation, was successfully accomplished. Three students went to Cambridge, the most successful in a class all of whom did well. A plumber and a printer's reader with to Selwyn College, an elementary schoolmitres to Newsham Two were able to take advantage of the whole month; the third (being a family man) could only spare a fortinght from his work, but all speak warmly of the pleasure and profit they have derived. The following are some extracts from their letters.

extracts from their letters.

One says —"I took chemistry and geology on alternate days, be-sides attending the majority of the angle lectures. The work being mostly of a practical kind, has been intensely interesting."

Another, after an enthusiastic description of the place, the architecture, and the College gardens, goes on:—"Everybody was mo! kind, cordial, and sociable, without the slightest suswas mo t kind, cordial, and sociable, without the slightest sus-piction of sittlifies or formality, of condescension or spatronage More than this, everybody we met seemed to be studying our interests especially, and doing all in their power to make our stay as enjoyable as possible. In science, geology was the only subject I was permitted to take up. In literature and art I attended courses on Browning and Tennyson, and on Greek art, Greek instory, and Herodotus, also single lectures on Leopold Ranke, and College Life Past and Present. Leopold Ranke, and College Life rast and Freenith hepe to continue these studies as far as possible in my home reading. Beyond the actual instruction received in the I hope to committee to the reading. Beyond the actual instruction received in the lectures, there has been given an impetus to further study, from which a continuous benefit must be reaped, and I have obtained a clear idea of what a student's life in a University town is like. a clear side of what a student's lie in a University town is like "Cambridge opens its doors in this way only to members of University Extension classes, but at Oxford anyone may attend the clusses who pays the fee The authorities of our College accordingly offered scholar-hips to those of their students who passed highest in the bettered and Art examinations for electricity, passed highest in the Science and Art examinations for electricity, chemistry, and mechanical drawing. The results of these were not known early enough for the first half of the vacation classes, but the second fortnight in August was so much enjoyed that those who made the arrangements considered themselves well those who made the arrangements considered themselves well repaid for their trouble, though this was not small, for working men do not find it easy to get leave of absence for even a fortinght at a certain specified time "One of the most enjoyable holidays I ever spent," writes one, "I lave quite, a collection

holishys I ever spent, "writes one, "I have quite a collection of geological specimens collected on the exercision of geological specimens of geological specimens of geological specimens of the property of and women. Will not the school teacher's work have an added interest and dignity now she has seen (if only by a passing glimpse) what education is in its higher branches? Will not all of them feel that life contains something besides manual drudgery for weekly wages, and that those whose lot is exempt from irulgery of this kind are willing and anxious to share with them the results of culture and leisure? We live in times of a difficult ship between free men, who can be mutually helpful to each other just because their circumstances and advantages are different Feudalism was good in its day, but it has outlasted the conditions which made it so, and the "ladder from the

the conditions which made it so, and the "ladder from the quitte to the University" is an important instrument in effecting the transition analysis ossenshing better, the scholarships receive wher support from the public than they have done, it will be difficult in not impossible in carry them on efficiently? Our fees are necessarily to low that the insuitation can never be self-supporting. We charge it entrance fee, and it of a term for the first class, of for each additional class. AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE. WASHINGTON MEETING

THE month of August 1891 was distinguished by the most notable array at Washington of scientific meetings ever held in America The series began with the meeting of the American Society of Microscopists on August 11, and afterwards, consecutively or simultaneously, came those of the Association of American Agricultural Colleges and Experiment Stations; the Association of Official Agricultural Chemists: the Society for the Promotion of Agricultural Science; the American Chemical motion of Agricultural Science; the American Chemican Society; the Conference of American Chemists; the Association of Economic Entomologists; the American Association for the Advancement of Science; the Geo-logical Society of America; and the International Geological Congress.

The fortieth annual meeting of the American Association for the Advancement of Science was held from August 19-25, President Albert B. Prescott, Professor of Chemistry at the University of Michigan, in the chair The attendance of members was large; about one-third of all attending were residents of Washington, most of them employed in the various scientific Bureaus of the Government 227 papers were read before the Sections, and these together with the addresses of the President and Vice-Presidents, Reports of Committees, and other documents, brought up the entire number to 201

Prof George L Goodale, of Harvard University, deliered the annual address as retiring President subject-"Some of the Possibilities of Economic Botany

After giving an account of the meeting of the Australasian Association for the Advancement of Science, held at Christchurch, New Zealand, in January last, which he attended as delegate from the American Association, he proceeded to consider the subject above mentioned An abstract of the address follows

There is an enormous disproportion occasion ber of species of plants known to botanical science and the number of those which are used by man The species of flowering plants already described and named number about 107,000, but the number of species used on a fairly large scale by civilized man does not exceed I per cent The useful plants which are cultivated by man do not exceed one-third of this Can the short hat of useful plants be increased to advantage? After calling attention to the influence which synthetic chemistry exerts by the production of artificial vegetable products which can replace the natural artificial vegetatic profiliris which can replace the industrial products profile to took up the cereal grains as illustrations of the history and improvement of cultivated plants If all the cereals, like wheat, maire, yee, barley, oats, and rice, were now to be swept out of existence, we should not know positively where to turn for new species of grasses with which to begin again. He drew a picture of the condition of civilized man if all the known varieties of the cereal grasses should become extinct, and then pointed out the probable manner in which our experiment stations would have to choose and improve the grains of certain grasses which are not used to-day. He expressed the belief that our well-equipped stations would give us satisfactory substitutes for our cereals within a period not exceeding that of two generations of our race. But why do not experimenters attempt to improve our present neglected resources of this character? Because we all prefer to move in lines of least resistance, letting well enough alone. Plants which have been long cultivated are more susceptible to the influence of changes in surroundings, and hence of improvement, than those which are just removed from the field to the garden Tracing the recent history of our cereals, he expressed his conviction that there is no probability that any new cereals will be added to our present list, but improvements will continue to be made in those which we have,

He included under the term vegetables all plants employed for table use, such as salads and relishes potato and sweet potato, the pumpin and squash, the red or capsicum peppers, and the tomato, are of American origin. All the others are, most probably, natives of the Old World. Only one plant coming in this class has been derived from Australasia-New Zealand spinach (Tetra-

Among the vegetables and salad plants longest in cultivation are turnip, onion, cabbage, purslane, the large 45% NO. 1142, VOL. 44]

bean (Faba), chick-pea, lentil, and garden pea—which have an antiquity of at least 4000 years. Next in age are radish, carrot, beet, garlee, garden-cress and celery, lettuce, asparagus and the leek, three or four legumes, and the black peppers The most prominent recent ones are parsnip, parsley, oyster-plant, artichoke, endive, and from the list.

There is an astonishing number of varieties, which represent an enormous amount of horticultural work, each race (that is, a variety which comes true to seed) having

been envolved by patient care and waiting.

For future development be recommends (1) Arracacha esculenta, of the parsley family, which is now cultivated in South America, near the Isthmus; (2) Ullucus or Ollucus, of the beet or spinach family , (3) the so-called Chinese artichoke from Japan

He recommends a more thorough examination of Japanese vegetables, owing to the similarity of Japanese

and Eastern North American flora

Attention was called to the extraordinary changes produced in the commercial relations of fruits by canning and swift transportation, and the opinion was expressed that before long it would be possible to place many more of the delicious fruits of the tropics in northern markets: and even, with increasing knowledge of microbes, to preserve fruit for almost any reasonable time. Such discoveries would diminish zeal in the search for new fruits

The improvement of fruits within historic times has been such that fruits which would once have been highly esteemed would to-day be passed by as unworthy of

notice

The list of seedless fruits may probably be materially neithered. The common seedless fruits are banana and lengthened The common seedless fruits are banana and pineapple Darwin mentions also bread-fruit, pomegranate, azarole, and date-palms, and says that their size and development are usually regarded as the cause of their sterility, whereas he regards sterility as rather the result than the cause of increased development

Prof Goodale expressed the conviction that there is no reason why we should not have seedless strawberries. blackberries, raspberries, and grapes, coreless apples and pears, and stoneless plums, cherries, and peaches,

propagated by bud-division

Promising timbers and cabinet woods, fibres, tanning materials, rubbers, and similar products were discussed in turn, the last class to be considered being fragrant flowers and plants for the florist. The necessity for caution in the introduction of new plants, lest they should prove pests by their wide dispersion through arable lands, as sweetbriar has in some parts of New Zealand, was fully illustrated. The agencies for examining useful plants were botanic gardens, museums of economic botany, and experiment stations

SECTION A-Mathematics and Astronomy.

The address by Prof E W 11yde, of Cincinatti, the President of the Section, was on the evolution of algebra, in which he traced the historical development of this branch of mathehe traced the hatorical development of this braight of mathematics, beginning with the almost preshitors Egyptian Ahmes, then giving a very full account of the Greek Diophantus, and then giving a very full account of the Greek Diophantus, and then giving the state of the Greek Diophantus, and the Greek Diophantus, and the Greek Diophantus, and the Greek Greek Greek Tessilis The Hindoon, Arya. Bhatta about 00 B C, and Bahama Gupla; 200 A D., were discussed, and were presented as like source of Arabana sighers, and thus of the Papers read before this Section neulade cone on the latitude of the Siyre Observatory, by C L. Doolittic, and on the seculiar variation of terretiral laitudes, by George C Commiscole. The results of the investigations appear to be proof of a secular variation of terretiral laitudes, by George C Commiscole. The results of the investigations appear to be proof of a secular variation of control Pole amounting to about 41 seconds in a Centrely.

century.

Frask H. Bigelow exhibited and described a new aurorancilinometer which will be sent to Alaska this autumn, and
valuable results are expected in the study of the aurora.

One entire session of this and the Physical Section jointly was devoted to an elaborate monograph by A Macfarlane, on principles of the algebra of physics.

SECTION B-Physics

Prof. F. E. Nipher, President of Section B, opened the pro-ceedings with an address on the functions and nature of the ether of space Many reasons formerly given for the existence ether of space Many reasons tormerry given for the extensive of such an ether, he said, no longer exist. For tenerny the state of the s but absent in fact, might be dispensed with in the theory by making its velocity zero, and that this does not involve an unstable condition of the medium, and is therefore admissible The showing up of light in space occupied by matter shows that the ether within must either be more dense (as Fresnel beheved) or less clastic than that existing in free space. It is certainly very difficult to understand what there can be in the molecules of matter which can increase the density of an incompressible medium. The beautiful experiment of Michelson and Morley shows apparently that the ether at the surface of the earth mov with it. It is dragged along as if it were a vivid liquid. The It is a sun which is maintained permanently without the cxpenditure of energy It seems, therefore, that the resistance to shear which shows itself in the adhesion of the ether to the moving earth must be a rigidity due in some way to inotion. Other experiments of Michelson and Morley on the motion of Other experiments of Michelson and Morley on the motion of light in moving columns of water have been taken as proof that the ether in water is condensed to nine sixteenths of its volume in air. The ether in water certainly hehaves us if it were more dense, but it is another matter to say that it is so. It seems im. in air. The ether in water certainiy nenaves wa, in were more dene, but it is another matter to say that it is on. It ceems im probable. It is still a mathematical fiction which overs a gry in our knowledge of the ether. The speaker thought that the experiment should be repeated with water at rest within a tube which should be mounted on elastic supports in a moving rail-The water tube and observer's scat should be rigidly WAY COT connected and swung on dampened spring supports from the top and sides of the car The question to he settled is whether the ether or any part of it is at rest in space, and does it sweep through the interior of bodies which move through it as wind sweeps through the leaves and branches of a tree. This form of sweens through the leaves and branches of a tree the experiment is the one contemplated by Eisenlohr's analysis leading to Fresnel's formula, and it is capable of great variations in the conditions of experiment. It is, however, more difficult and more expensive than the one so well executed by Michelson and

more expensive than the one so well executed by Michelson and Morley. Whatever its results may be, it promises to add greatly to our knowledge of the physics of the other. Prof. E. W. Morley, who has for several years been conduct-ing researches under the auspices of, and with funds supplied by, the Association, read papers describing his method of de-termining the coefficient of expansion by means of interference length as accurately as Fizeau did that of half-inch bars

length as accurately as Fixeau did that of half-inch bars.

C. B Thwing read npaper on colour photography by 1app-mant's process, and exhibited samples which show a tange of

II. A Hazen, of the U.S. Signal Service, discussed the question "Do tornadoes whit?", and gave results of elaborate and careful suddy of tornadoes and of the daw left by them, from which he concludes that the common notion of a whirl in tornadoes is unfounded

SECTION C-Chemistry.

Prof. R. C. Kedrie, of the Agricultural College, Michigan. chose the subject of alchemy for his annual address

Thirty-three papers were read before this Section, and the meeting was characterized by the Secretary of the Section as the most valuable ever held.

the most valuable ever held.

Mr. Morley contributed valuable material to this Section also, in regard to the synthesis of weighed quantities of water from weighed quantities of water from weighed quantities of water from the contribution of the

NO. 1142. VOL. 44

"Biological Functions of the Lecithines" was the title of a paper by Walter Maxwell In a paper presented by Mr. Max-well at the 1850 meeting of the Association, he showed that a vegetable organism, during the initial stages of growth and under the action of the fements operating in germination, possesses the power of taking the phosphorus present in seeds or in soils, as mineral phosphates, separating the phosphorus from the inorganic combination, and causing it to reappear in the young plantlet in an organic form as a lecithine. In brief, own that the lecithine bodies are a medium through which the phosphorus of the mineral kingdom passes over into the vegetable kingdom. In the second part of Mr Maxwell's paper he went on to show that the lecithine bodies, on the other hand, present in the animal kingdom revert to the mineral form under the action of the ferments present in the animal organism. a hen The phosphorus contained in the egg, in the respective a hen The phospherus contained in the egg, in the respective forms of mineral phosphetas and organic phosphetas compounds as ketthines, was determined in the next place, the eggs were noticulated, and the products of incubation were studied it was funul that the phosphorus contained in the natural egg as a lecitabre responsered in the uncubation products a calcium phospherus products and the products of the product as calcium phospherus products and the products are consistent of the products are consistent or the product of the product as calcium phospherus products are consistent or the product of the product of the products of the product o

lecthine respicated in the incusation product as carcium pro-plint, and forming the hone of the chicken. Were adduced to show that the logarithms of the molecular weights of the hydro-carbons have a direct relation to the fusing and bealing points of these which the control of the control of the control of the three which is the control of the control of the control of the three which is the control of the control of the control of the three which is the control of where logarithms exist between changes in physical or chemical

SECTION D-Mechanical Science and Engineering

The President of this Section, and a soften one of the Vice-Presidents of the Association, is 1/rof Thomas Gray, of I ere flaste, Ind., the inventor of a great variety of ingenious apprains, including the seromoscopic and scienograph shown the Association on their excursion to Terre Haute last year, Ilis addiess was a carefully prepared discourse on problems in mathematical science. It was technical in character, and dealt with the teachings of mathematics and physics in their application to engineering

Among the papers before this Section was one on Government timber tests, by B F Permor, Chief of the Bureau of Forestry. timer tests, by her rermor, chief of the backet of referring the said there had been mangurated in the forestry division of the Department of Agriculture a comprehensive states of tests and examinations of American timbers, the ultimate object of which is the solution of a biological problem—namely, to evablish the relation of technical and physical qualities to each other and to conditions of growth. In the pursuit of this investigation, naturally, many questions of immediate practical value in the use of wood for engineering purposes will be solved. the novelty in this enterprise lies mainly in its comprehensivenis and scope. A very large number of lests alone on material of known origin and condition, and an exhaustive examination of the same will permit generalization and the recognition of lives of inter-relation. The work requires the organization of four distinct departments. First, the selection of test material four distinct departments from as many essentially different climatic and soil conditions as from ns many essentially different climinic and value controls as the species may occupy, five fully-instured and two young trees being carefully selected on each site and cut up for test material, secondly, the examination of the structure and playes al condition of the test material, requiring the minutest detail, thirdly, the usual testing with special care, and, lastly, the compilation and with the physical examination and the known conditions of growth. Besides more trustworthy data thin hitherto attainable growin. Besittes more trustworiny data than hinerio atlantable of the qualities of our piningpal timber, there is to be gained from this investigation a knowledge of conditions under which destrable qualities can be produced by the forest grower Prof. J. B. Johnson rend a paper on the United States tests of strength of American woods, made at the Washington University Testing Laboratory, 51 Louis.

SECTION E .- Geology and Geography.

Prof. J. J. Stevenson, of New York, presided His address was on the relations of the Cheming and Catkull on the eastern side of the Applachana Basin. He timed the groups along the eastern outcrop from Tennessee into New York, acrow Southern and Western Pennsylvania, and eastward through Northern Pennsylvania, and Ashburtte in Pennsylvania, and

of Prof Stevenson in Virginia and Pennsylvania, incidentally referring to the work of Profs Hall and Williams in New York. In this way the continuity of the section was shown, and the In this way the continuity of the section was shown, and the magnificance of the variations was insisted upon strongly. An area in South eastern New York and North eastern Pennsylvania, in which the Chemung group is almost without trace of animal or vegetable life through the greater part of the thickness was described. The absence of life was thought to be due, not to fresh water, but to turbidity of the water in a shallow basin near the land The facts that the horizons of shi-reamins are much lower in the column than had been supposed, and that the plant-remains come in like manner from the home group, were thought to be of especial interest and importance. The conclusions to which the specker was led were -(1) That the series from the beginning of the Portage to the end of the series from the beginning of the Portage to the end of the deviced into these problem-ble Yorking, the Chewaung, and the Castkill (2) That the disappearance of animal and vegetable life on to great a pure of this area toward the close of the period was due simply to gradual extension of conditions exiting, perhaps, a certly as the Hamilton period in South-cinesid sea, but that the influx of great rivers with their load of differs made conditions in the shallow basin such that assimal life could not exist. (4) That in the prevent state of our knowledge was zero justified in molating the Cheming period in the ending the Cheming period in the Carboniferous age

the Carboniferous age
Modwithranding the inpending meetings of national and
international Geological Societies, this Section was fully occufifty, and the William Hallock read a paper entitled "A
Frelimmany Report of Observations at the Deep Well, Wheelng, W Va " The question as to the conditions which exist in
the intern of the earth, said Mr Hallock, has always attracted
much attention. The most important factor in the solution of much attention. The most important factor in the sources of this riddle is the determination or estimation of the temperatures there existing. The British Association has for years seized there existing. The British Association has for years seeze every opportunity to obtain data as to the rate at which the every opportunity to onlain data as to the rate at which the temperature increases as the eath creat is penetrated. The temperature increases are the early of the early of the Mr E. Dunker, of Halle, Germany, and were obtained from a 4170 foot well at Sprencherg, no far from Brinn, and a 5740-foot well at Schladabach, near Leptig. These wells are both full of water, the circulation of which ytutaet results or renders full of water, the circulation of which vitates results or renders claborate apparatus indupenshly, and the thermometers must be protected from the pressure. The Wheeling deep well, annk by the Wheeling Development Company, and hy them generously defined to 100 per constructions of the pressure of the protection of t lowered and raised, and depths measured by a steel wire

Inasmuch as the bottom of the well is some 3700 feet below sea level, it seemed worth while to attempt barometer readings sen ieven, it seemed worth while to attempt barometer readings in it. The instruments used proved ill adapted to the work, and the results were unsatisfactory. Samples of air were taken at the bottom, but could not be analyzed in time for use. A series of observations in a coal mine near the well gave as a very probable value of the temperature of the top invariable stratum. probable value of the temperature of the top invariable stratum 51; 3F. From the mean annual temperature of Marteita and Steubenville it might be taken at 52; 2F. Drilling is temperature of many the resolute. Mr. Auton, Bayman, of the Drelopnent Company, has generously guaranteed half the expense, and what is wanted to that so more one shall furnish the other 3000 dollars, and enable the Wheeling well to be lifted from the second to the first place among the deep wells of the world

SECTION F .- Biology

Prof John M Coulter, President of Indiana State University, gave the annual address, as President of Section F, on the future of systematic bolany. He contended that for the systematis to to day and of the future there must be three distinct lines of work, related to each other in natural sequence in the order presented, and each turning over its completed product to the next. (1) The Collection and Description of Plaints to expressed great gratitude to the noble army of self-denying pioneer collectors, but claimed that the time had now com-when the same amount of labour could be expended to better when the same amount of labour could be expended to better advantage, and that a race of itself workers must be trained who shall follow their profession as distinctly and scientifically as the race of topographers. In reference to the work of description he read an aupublished note of Prof. Ana Gray, in which were incompletent. The speaker also expressed the opinion that the exclasive use of gross organs in the description of higher plants would be given up, and that the more stable minute theracter would prove valuable axis in steadying disgrayments. A diagree in the use of these minute characters was pointed out, ur, the tendency to we a mighe set of minute from to it. The character of a species is an extremely composite not thoroughly equipped great caution in publication." (3) The Construction of a Natural System.—The speaker spoke of the necessary of constructing a natural system with easy advance in the knowledge of affinities, as a coarement summary of information of the state of the consolidation summary as a follows—"The points presented in this consideration of the third phase of systematic bodary are that the last and highest expression of systematic work is the construction of a natural system, based upon the accumulation of those who collect and desembe, and those who study life-histories, that this work involves the completest command of literature and the highest powers of generalization, tempted with every advance in knowledge; and that all the known facts of affinity, thus brought within reach, should be expressed in all systematic literature."

expressed in all systematic interature.

This Section, as usual, was the most crowded of all, forty-seven papers having been read before the Section itself, and many more before its two off-hoots, the Botanical and the Entomological Club. This was another of the Sections which its Secretary considered to have had the most successful meeting. its Secretary considered to have had the most successful meeting on record. A feasure now at every annual senson in the report of the property of the property

SECTION H-Anthropology

The youngest Vice-President at this session, if not the youngest man who ever held a Vice-Presidential office in the American Association, is Prof. Joseph Jastrow, whose age is 28 years His address was enuited. "The Natural History of Analogy" Major J W. Powell, Chief of the U.S. Geological Survey, exhibited and explained his inguistic map of North America, on which he showed the classification of languages of the

on which he showed the classification of languages of the aborigines

Mr Cushing read a paper on the Zuñi Indians, and danced the Messiah dance, which a few months ago was so much talked about, and almost involved a war with the Government

schemes which are now so vehemetry urged upon Congress

The general business of the Association included a change in the constitution, so as to adjust fifty foreign honorary members, and many recommendations to Congress as to forestry, water supply and management, and other topics Preliminary arangements were made to participate in the Columbian World's Fan in 1893 A Committee was appointed to solicit donations for the endowment of the Association with a fund of at least \$100,000 Three hundred and seventy one new members were elected, arrice numbers and seventy one new members were elected, bringing the total membership up to about 2300, which is highwater mark in the hatory of the Association Prof. Joseph Le Conte, of California, was elected President, and the Association adjourned, to meet at Rochester, N.Y., on the third Wendesday of August 1892

RAIN-MAKING IN TEXAS.

THE announcement in the Standard about a fortnight since, that rain had been artificially produced in Texas by exploding oxyhydrogen balloons and dynamite, was probably received by most scientific men with a sus-pension of judgment. The somewhat sensational form of the report, the emphasis with which it dwelt on the unfavourable antecedent conditions, and the omission of all details that might enable us to form some rough estimate of the forces employed and of the resulting effects, seemed calculated to appeal to the barren emotions of astonishment and love of the marvellous rather than to astonishment and love of the marvellous rather than to the sober judgment of well-balanced minds; and but for the fact that the experiments were stated to have been made by the officers of the U.S. Signal Service, which, on the hypothesis of a hoax, would have been a needless on the hypothesis of a nost, would have been a necules challenge to speedy dental, one might have been disposed to regard the story as only an additional instance of a kind of produce for which the Western States are somewhat notorious. The further accounts that have now reached us prove, however, that this is not one of Jonathan's amusing attempts to play off on the cre-dulty of his simple-minded cousins across the Atlantic. Not only have experiments of the kind described been actually made, but they have been apparently successful, and they seem to have been repeated sufficiently often to and they seem to have been repeated sunciently often to render it at least improbable that this success has been entirely fortutous. The improbable features of the Standard's report are, indeed, somewhat toned down, the dryness of the local atmosphere was by no means so great as was to be inferred from the vague language of the Standard's informant, but, as far as can be judged from the notices now before us, it seems unlikely that the rain which followed General Dyrenfurth's experiments would have occurred in the undisturbed course of natural evente

The experiments were made at a place known as Runch C. One writer states that an intermittent series of experiments had been carried out for three weeks, and that "not in a single instance has rain failed to fall within ten or twelve hours after the explosion" But the number of trials is not stated-an omission the more to be regretted, because the improbability that the results are fortuitous increases in a certain geometric ratio of the counts of those made on August 18, 26, and apparently the morning of the 27th, and it is by no means clear that the evidence is not limited to these, although the expression quoted above would seem to imply otherwise The first, that of August 18, was made about 3 p m.

There were at the time a few scattered clouds, but no indication of rain.

The reading of the barometer is not reported, but the relative humidity of the air immediately before the experiments (presumably at the earth's surface) was not more than 60 per cent of saturation. An oxy-hydrogen balloon, the capacity of which is not stated, was exploded by electricity at an altitude of a mile and a quarter. Several kites, with packets of dynamite attached, were sent up immediately after the balloon, and the charges exploded by similar means, and "rendrock powder was distributed for a distance of two and threequarter miles from head-quarters, and fired by igniting dynamos" These explosions "sent up great volumes of white smoke, which rose only a short distance, and was then beaten down by heavy rain, which at once began falling and continued for four hours and twenty minutes" Prof Curus, the meteorologist of the expedition, esti-mates that the rain covered an area of not less than 1000

On August 26 it is stated that "balloons containing several thousand feet of oxyhydrogen gas were sent up and exploded at heights varying from 1000 to 10,000 feet, and at sundown batteries on the ground began their and at sundown batteries on the ground began their work, and until 10 30 pm a constant cannonade was carried on under a sky of perfect clearness, lit by countless stars of a bniliancy seldom seen in the north. The barometer promised fair, and the hygrometer stood between dry and very dry," whatever these expressions may mean. The account continues.—" 4111 pm General Dyrenfurth withdrew his forces, and all retired for the night Sleep, however, was soon interrupted, for at a m. the first return fire flashed from the heavens, when the rain-makers were roused by a crashing peal of thunder, and the rain was soon beating on the roof. At sunrise a magnificent double bow arrhed the heavens, and the downfall of rain did not cease till 8 o'clock a m. A number of heavy charges of dynamite were then made, and after every one the drops again poured down, till at last the clouds were entirely expended."

in these quotations is given all that is essential in the newspaper reports now before us. Although deficient in many details that it would be desirable to know, they are written by one who witnessed what he described, and there seems no reason whatever to doubt their genuineness and good faith, we may therefore, discuss the information they afford, without imagivings of its sub-

stantial trustworthiness.

It is not antecedently improbable that, in certain states of the atmosphere, the liberation of a large amount of heated gas consisting wholly or in great part of water vapour, at an elevation where acrial movements are but little retarded by terrestrial friction, may suffice to generate an ascending current, and elementary physical considerations teach us that a the lower level, will in ascending speedily become saturated and condense its surplus vapour, first as cloud, and eventually as rain, not indeed by acquiring more vapour, but in virtue of dynamic cooling as it progressively expands under the diminished pressure of greater altitudes. But unless the atmospheric strata thus immediately affected be already in a condition of unstable equilibrium, unless the vertical decrease of temperature in these strata is already somewhat greater than the adiabatic rate of decrement, so that the ascending movement once started can be maintained by the store of energy already present in the form of sensible temperature and the latent heat of the included vapour, the effect must of necessity be temporary and local-inore of the nature of a small thunder-storm, or cloud-burst, than of the widely extended or sporadic rainfall that accompanies a baro-

In fact, the possibility of rainfall production depends on the possibility of producing and maintaining an upward movement in the atmosphere. There is always some vapour present in the air, generally sufficient to form clouds when dynamically cooled by an ascent with the state of the production of the production of the production of the production of the ground and warmed by its contact, may be very dry as judged by our feelings and by the evidence of the hydrometer. The amount of energy yielded by any moderate provision of oxyhydrogen balloons and dynamie is but infinitesimal in comparison to the production of the p

It seems highly probable that on August 18 the atmoshere was in this unstable condition. Even in the warm stratum resting on the ground, the humidity was existed at some height, and rain began to fall almost immediately on the conclusion of the explosions. It may be noticed, too, that the time of day was that at which the barometer is lowest and the humidity highest in the cloudties. The strategies of the conclusion of the explosions of the pround surface. In the absence, then, of any observations of the temperature and humidity of the strata primarily stried up by the exploding acilions and dynamite, may be a supplied to the continuous of the continuous of the ascending currents once a few of the continuous to maintain ascending currents once a few of the communicate the disturbance to regions a round. On the 26th, the atmosphere was evidently in a much more mert condition, and four hours elapsed before rain fell, the disturbance being then apparently more local, and of the nature of a thinder-storm. However, with the meagre data as yet before us, it would be premature to attempt any cruical discussion of the processes in opera-

It is needless to say that popular theorizing, on this as on most other physical phenomena, concerns itself chiefly with the things that are most obvious to the senses, but often have little or nothing to do with the process. we find that attention has been fixed on the explosion : and we are told that the idea of breaking clouds by producing a motion in the air, and so destroying the equicoalescence form rain, is not a new one, that it was the custom to keep a cannon in French villages, with which to fire at passing clouds and thus hasten the downpour, that at the battles of Dresden and Waterloo the concussion of the air by the cannonade led to the descent of torrential showers, and we are reminded that "in the same way" rain follows a peal of thunder caused by the passage of a lightning-flash through a moisture-laden atmosphere, &c Now, all this noise and disturbance have no more to do with the production of rainfall than has the thrashing which the village rain-maker of Central India receives from his fellow villagers to stimulate him to fresh exertions when he is thought to have neglected the performance of his official duties, or the London street-boy's whistle, with which Sir Sainuel Baker startled a rain-making king in the Southern Soudan, and which was followed by such a deluge that even the rain-making potentate implored him to arrest the working of the spell. The effect of a concussion, as such, is to produce an instantaneous compression of the air, and a momentary heating in a wave which travels away at the rate of about 1000 feet per second, and 18 incapable of generating any translational movement of the atmosphere, and certainly of promoting condensation. Nor do we know of any recorded observations in support of the idea that it can cause the coalescence of cloud corpuscles into raindrops Neither does the concussion of the air by a thunder-clap stand to the downpour that follows it in the physical relation of cause to effect In this case Sir John Herschel adopts the opinion originally put forward by Eeles, that the order of succession is the reverse of that here assumed, that the formation of the jain-drop is the antecedent phenomenon, and the lightning-flash (and ergo the thunder) the consequent, the electrical discharge ergo me trauncer (no consequent, the electrical discharge being determined by the sudden concentration of the electricity of (say) one thousand corpuscles on the surface of the single resulting rain drop, in which case its intensity would be increased ten-fold What case its intensity would be increased ten-told. What causes the coalescence is still a matter of much obscurity, though some light has been thrown upon it by the ingenious experiment evaluted by Mr. Shel ford Bidwell at the Royal Society's conversazione on May 14, 1800, and described in vol. Min [6] 31) of this pournal. When the shadow of a small [condensing] steam jet was thrown upon a white screen, under ordinary conditions, it was of feeble intensity and of a neutral tint . but when the jet was electrified, the density of the shadow was at once greatly increased, and it assumed a peculiar orange-brown tint. It appeared that electrification promoted the coalescence of the exceedingly minute particles of water contained in the jet, thus forming drops large enough to obstruct the more refrangible rays of light. On this view, then, electrification would appear to be the cause of coalescence, and the electrical discharge the ulterior result; but as yet we know too little of the

This story has probably been fold by Sir Samuel in one of his well-known works on Africa, and is too good to be spoilt by condensation. It is at all events, authentic, the present writer having heard it from his own lipt at a Sinia diamer table.

molecular processes concerned in the formation of a randrop to attempt anything like a complete theory. In conclusion, while we cannot but recognie the high interest of General Dyrenfurth's results, with the imperfect information at present before as we the process of the conclusion of the conclusion of the kind that many of the essential circumstances are scarcely wer recorded, or perhaps even capable of being brought within the limits of observation; and thus the logical conditions of a proved conclusion cannot be fulfilled For instance, it is written to the conditions of a proved conclusion cannot be fulfilled For instance, it is written to the conditions of a proved conclusion cannot be fulfilled standard to the conditions of a proved conclusion cannot be fulfilled. For instance, it is written to the condition of the condit

NOTES

This Permanent Committee of the International Committee of Weight and Measures in now holding its meeting at 8' sees, near Pars. The Committee includes Dr. Toerster (Germany), M. J. Hertrand (France), P. Beonti, Director of the Bureau at Scivres, Mr. H. J. Chaney (Great Britain), Prof. Good, Citaly); Prof. Kimpper (Hungary), Prof. Lang (Austria), Mr. H. de Macedo (Portugal), M. Stas (Belgumi), Prof. Thaden (Swedien); Dr. Wild (Ravius). The Committee has recently loit its President (General Ishalen), and one of the objects of the present meeting to to let at new President, an election which will doubtless fall on thesemor member of the Committee, Dr. Foorster.

THE members of the Heilprin Expedition, who have lately returned from the west coast of Greenland, give an extremely unfavourable account of the position in which they were obliged to leave Lieutenant Peary. His leg was broken in Mclville Bay on July 11 Dr. Hughes, who has recorded in the Philadelphia Press the adventures of the Expedition, describes how the accident happened "While we were going astern for the last time," he says, " to make the butt that forced us through a barrier of ice into comparatively clear water, Lieutenant Peary stepped behind the wheel-house to see how things were going With a crash the rudder struck a piece of ice, and the next instant his leg was crushed between the rudder gearing and the side of the wheel-house He was carried below into the cabin, when an examination showed that his right leg was broken square across just above the knee Everything possible was done for him When he had recovered from the shock, and had thought the matter over, he decided to go on to Whale Sound, trusting that by next spring his leg would be so far mended that he would be shie to accomplish the object of his expedition. His friends thought it would be better for him to return, but they could not help admiring his spirit, and resolved to do everything in their power to further his aim. The shores of Whale Sound proved to be completely blocked with ice, so the Kite steamed north to McCormick Bay, on the northern shore of Murchison Sound, which they reached on July 25. Here a space of about two miles was comparatively clear; and Lieutenant Peary's men went ashore, and reported that the place was well suited for A site was selected on the south shore their head-quarters of McCormick Bay, in latitude 77° 43', and a wooden house erected, which Lieutenant Peary declared to be "substantial

and warm enough." On July 30 the Helprin party had to leave him, which they did with sad forebodings. Mrs. Peary bravely masted on remaining with her humband, and they have are companions. The Leutenant hopes to start in the spring for the unexplored interior of Greenland, but Dr Highes says. "It is the deliberate opinion of all our party—and this opinion is indersed fully by all the officers of the Arize—that unless a relief expedituou in sent to Leutenant Peary next summer, he and his party will never be seen again alwe." It is underful whether the food supply a sufficient, and it is thought most improbable that whates will take them the whole boars, in which they would have to traverse 500 miles of occan "filled with floes and lengty, and often shrouded with fog or swept by terrible storms."

An earthquake of great violence caused immense damage in the Republic of San Salvador on September 9 According to reports sent from the capital of the country to the New York Herald, there had been indications for several days that a seismic disturbance of more than usual power might be expected The volcances of San Salvador, San Miguel, and Izalco had been un usually active, and deep subterranean rumblings with slight carth tremors had been felt At 1 55 a.m., on September 9. the carthonake began in the city of San Salvador with a slight tiemor, which gradually augmented The duration of the first shock was ten seconds, during which time a hightful subterrancan noise was audible in every part of the city While the shock lasted, the earth rose and fell in long waves, and even strong men were unable to keep their feet | I'he walls of houses cracked, and then tottered and fell In the capital alone 40 persons were killed, and 50 or 60 seriously injured. The experience of towns in the country seems to have been still worse Of 320 houses at Comasagua only eigh, remain standing, and the to-s of life there was great Analquito has also been almost completely destroyed, and Cojutepeque, Santa Tecla, San Pedro, and Masahuet were so badly shaken as to be practically ruined It is feared that the earthquake has been even more disastrous than those of 1854 and 1873

15 the Isle of Fayal, among the Azores, several shocks of carbonake were felt on August 27 and 28

MR TUCKWELL writes to us from Loughrigg, Ambleside, that an aurora was seen there on Friday night, September 11 liberach spanned the heavent from south-west to northe-saxt, passing nearly through the zenth li was white, with slight cursactions at its south-west base. It was first seen at 9 p m. it had fided by 10 o'clock

A xxw department of physics and electrical engineering will be begin this assion at the new branch of the Mauchester Technical School in Whitworth Street, where a large well-lighted warehouse is being fitted up of crite purpose. The building will be lighted by electricity, the installation being fitted up with sepecial regard to instruction. For the latter purpose, the electric light installation in the Central School in Prances Street will also be available.

THE Library Association is bolding its annual meeting this week at Nottingham. Mr Robert Harrison, of the London Library, presides. The meeting began yesterday in the large theatre of the Nottingham University College.

THE Industrial Society of Mulhouse has issued a programme of prices which it proposes to give for work done in the year 1891-9a. A copy will be sent to anyone who applies for it to the Secretary of the Society. The prizes are very numerous,

and are to be granted for work of many different kinds in connection with the application of scientific methods to industry.

A CONFERNCE on Confers will be held at Chiswock, in October connection with the Royal Horticultural Society, in October II is hoped that this Conference will not only draw attention to the best of these trees and airube from a garden or landscape point of view, but show what are the best varieties to plant for English-grown timber, as well as the different uses and usitabilities of the various foreign-grown timbers. The co-operation of landowners and others who may have planted these trees or shrubs in years past, or who take a present interest in them, is specially jurited.

DREDERS working in the Tiber to prepare for the construction of a new embankment brought up on September 12 a magnificent ancient Roman bronze helmet. It is perfectly preserved, and is decorated with bas-relefs. Signor Rossi, the Italian archeologist, sasigns it to the second censury before the Chains and Chain of the Chain and Chain of the Chain of the

ACCORDING to the Calcutta correspondent of the Times, it is understood that the Ameer of Cabul is taking steps to obtain from England a geologist, a chemist, two miners, and a number of mechanics.

THE Royal Meteorological Institute of the Netherlands has just issued another nieful work in maritime meteorology, viz "Routes for Steamships between Aden and the Straits of Sunda." A previous edition appeared in 1881, but since that time steam navigation to the Dutch Indies has greatly increased, and con sequently the number of logs received has afforded sufficient materials to allow of a fuller discussion of the outward and homeward routes for each month. Although there is a certain amount of regularity both as regards the monsoons and currents. yet there are considerable differences both in force and direction in the same months of different years, which cannot be taken into account in laying down general routes, but tracks laid down with great care from the most complete data available will give the best chance of successful passages. We cannot enter here into the details of the results, but we may mention that the tables and charts contained in the work show for each 10° of longitude the number of vessels which have cut those mendians in different latitudes, and the means of the number of hours taken. The tracks show that a very considerable divergence from the most direct routes is recommended in certain months, according as the east or west monsoon may be blowing. The usefulness of the work is attested by the fact that copies have been ordered for their vessels by the French, Russian, and Italian Governments

It a expected that us no other department of the "World's Colombus Exposition" will there be a greater diversity of Colombus Exposition will there be a greater diversity of exhibits than in that of mines and mining. Not only will there be a magnificent array of diamoned, opuls, mertald, and other gems, and of the precious metals, but a most extensive collections of truo, copper, feed, and other occus, and of the products; of of truo, copper, feed, and other occus, and of the building stone, of only genits, martile, sandstone, and other building stone, of solis, salt, and peterodeum. A sub department will lake special charge of the coal and iron exhibit, and later of that of copper and lead.

Mr. O. CHANUTF, a well known engineer of Chicago, has been studying the methods of preparing wood demically to resist decay, and has expressed the opinion that great economies might bus realized in America by the general sdoption of these methods on rallways Science says he recently examined some

NO. 1142, VOL. 44]

experimental railroad ties of the most perishable kinds of wood prepared by what is known as the alno-tannin (Wellhouse) process, in St. Louis, in 1881 and 1882, and laid in the tracks of the Atchison, Topeka, and Santa Fe Railroad, at Topeka, Kan , and La Junta, Col. After nine or ten years' exposure they show excellent results, whereas they would have leated but from one to four years if unprepared. Unprepared ties of the same kind of timber, laid at the same time, adjoining to the prepared ties. have all decayed and been taken up, while present supersances indicate that the prepared ties (red oak, black oak, and Colorado pine) are likely to show an average life of ten to fifteen years or more. Mr Chanute calls attention to the fact that the zinctannin process not only preserves ties against decay, but hardens them as well it is found on one railroad that after three years' exposure treated hemlock ties hold the spike as well, and cut less under the rail than untreated white oak.

SOME time ago the Field Naturalists' Club of Victoria organuzed an excursion to the Kent group of islands, the object being to collect specimens, and to determine whether the group is most nearly related with Victoria, to which it is closest geographically, or with Tasmania At the annual conversations of the Club, held recently, Mr. C A Topp, the retiring President, referred to the results of the expedition. The bulk of the fauna and flora was found to be common to Victoria and Tasmania, but there were six or seven varieties of birds peculiar to Tasmania to two peculiar to Victoria. The conclusion was that the islands had been separated from Tasmania after that island was disjoined from the mainland. Among the plants, several forms were found varying somewhat from the typical forms of the same species on the mainland, while it was interesting to find that the arboreal short-eared opossum had changed his habits so far as not to feed on the leaves of the eucalypt, and to keep to the ground

In a paper in the American Engineering Magazine, on ventilation, Mr. Laurence Allen contends that in very many schools the quantity of pure air admitted is not sufficient to expel the foul air To maintain the air in a good sanitary condition in a properly constructed schoolroom, his experience confirms the amount required as stated by Billings, to wit, 60 cubic feet of air for each occupant per minute. For 100 pupils this amounts to 360,000 cubic feet per hour. How many schools come up to this requirement? In the United States, says Mr Allen, there are many schools that contain 100 pupils and do not introduce more than 25,000 feet of pure air per hour, and even that is rendered in a measure ineffective, because the air is not properly admitted. "The pupils do not die in the poisoned atmosphere ; many of them will appear reasonably healthy. So do many persons who visit and tarry in malarial districts. But though the effects are not immediate and striking, they are sure, permanent, and easy to be traced to their causes in after years, by those who make a study of disease and its causes. It is scarcely less humane to kill a child than, by wilfully ignoring sanitary requirements, to cripple it for life, physically, mentally, and morally, as children are being crippled to-day in the vile atmosphere of many schools."

IN a paper published in the current number of the Journal of the Anthropological Society, Mr. J. Latter refers to the great development of the arms and chests of the natives of Fakson's (Bowditch Haind, Union Group). He thinks it may be due to the fact that they are obliged to go about so much in canosa: Si Joseph Litter, who took part in the discussion which followed the resulting of this paper, remarked that he would not have the resulting of this paper, remarked that he would not have lengthening of the arms, although be could maderstand its resulting in moreased size of chest. He pointed out that the natives of Tongs were also accusioned to use canosa, and heppen it was not clear that the phenomenon could be traced to the cause sangend Mr. Later replied that, although the Tongananec canoos, canoo work is not so essential, a part of their lives a nec canoos, canoo work is not so essential, a part of their lives a it is in the case of the natives of Faksofon. The natives of the island of Tongarabh have many avocations quite apart from the set, for they live on an island twenty-two mules long, and many a villages are situated some distance from the water. The natives are villages are situated one distance from the water. The natives of Faksofit, on the other hand, live crowded together on a small islet situated on a ring of reefs, and to meet almost every need of their lives they must do more or less maddling.

MR IVAN PERSOR, the United States special census agent, has been engaged in taking the census of the natives of Nunivak Island, in Behring Ses, in 66° N let. He found the population to consist of over 600 natives. It was previously supprised that over 300 people occupied the usland There are no white men there, and the natives live in a most primitive style. Their only food is the flesh of the walrus, and their only wealth consists of ivery obtained from the tasks of that animal. There are few land otter, but, spart from these, the natives catch no further bearing animal.

Dit 1. Weister Five 1s of opinion that savage races possess the perception of colour to a greater degree than do civilized races. In a lecture lately delivered before the Franklin first text. Philadelphia, he stated that he had past concluded an examination of 250 Indian children, of whom 100 were boys Hind he selected too white boys from vanous parts of the United States, he would have found at least five of them colour blind among the Indian boys he did not discover a sugle case of colour-blindness. Some years ago he examined 250 Indian boys, and found two colour blind, a very low percentage when compared with the whites. Among the Indian girth he did not find any. Considering that only two females in every 1000 among whites are colour blind, he does not think it surprising that he did not find any excomples among the Indian girth.

DR J FRANK lately reported to the Chicago Medical Society the ease of a man who periodically sheds his skin. The shedding began in his first year, and has since then occurred regularly every July. He is taken with feverish tremors, increasing almost to paroxysms He undresses, lies down, and within a few minutes the skin of the chest begins to turn red The redness rapidly extends over the entire skin, and the feversh tremors continue uninterrupted for about twelve hours Then he rises, dresses, and walks about in perfect health. The skin now begins to neel, and ten hours later it comes off in great patches. From the arms and legs it can be peeled off exactly like gloves or stockings. As the old skin comes away, a new epidermis, as soft and nink as a haby's. is revealed This new skin to very sensitive, the patient has to wear softened gloves and moccasins for about a week After the old cuticle has been entirely removed, the finger and toe nails begin to drop off-new nails literally crowding them out Finally, the change is complete, the man has a new skin and a new outfit of nails, and is ready to return to the mines. A lady in Washington County, Nebraska, who is thirty-nine years old, has written to Dr Frank that since 1876 she has had a like experience every second or third year.

This Oreut Seed and Plant Company, San Diego, California, have issued an interesting descriptore hat of Californian trees and flowers. The writer thanks that there is perhaps no country in the world where the early spring flowers so change the face of the early from a desolate waste to a beautiful galedon as on the Padde coast—bills, means, moontains and valleys, and the arid plains of the de ert, alke quickly responding to the viriging rain. "California," he say, "has probably already farmined NO. 1142, VOL. 44]

to the horticulturist a greater variety of beautiful flowers and stately trees than any other State in the Union. Yet many others are awaiting the appreciation of man, or wasting their sweetness on the desert air "

A PAPER on malformations of the bill in brids, by Mr. W. Pyoraft, has been reprinted from the Transactions of the Lecenter Literary and Philotophical Society The most common kinds of malformation are those resulting from overgrowth of the borny sheath, and those arising from injury. Mr. Pyraft discusses these first, and then considers malformation due to embryonic disturbance

""Systoms's British Rainfall, 1890," which has lately been pulshade, contains, we need searcy; say, an enomess mass of information as to the distribution of ruin over the British Isles during the year to which the volume relates Mr Symons points out that the only important alteration in this issue is that due to the completion of the detend 1805-89, which has enabled han to use the average for that period as a basis of commanded to the completion of the detend 1805-89, which has enabled han to use the average for that period as a basis of common soft, and to the details evers as to the reset rain of flut 17.

THE operatives' lecture delivered at the Cardiff meeting of the British Association by Prof. Silvanus P. Thompson has been published by Messrs. E. and F. N. Spon. The subject is "Electricity in Mining."

"THE Hand-book of Januaca for 1891-92" has just been issued. This is the eleventh year of publication. Mr S P Misson and Mr T. Laurence Rockupth have done their best to present the fullest and latest information obtainable, and everyone who has occasion to consult the book will appreciate the care and thoroughness with which their task has been falfilled.

A New edition, revised and enlarged, of the "Alkali Makers" Pirocket-book, "by Prof Dr. Longe and Dr. Harter, will be usued in a few days in Mews Whittaker's Specialists' Series. At the size of the page has been somewhat increased, the designation "Hand-book" has been substituted for "Pockethook". The same publishers are about to issue "A Franciscal Hind-book on the Telephonic, "dealing specially with telephonic exchanges, by Mr. Joseph Poole

Messes Rattrey, I awrence, and Co have issued a second edition, revised and enlarged, of "Simple Recipes for Sixt-room Cookery," by Mrs Buck. True writer produces an excellent impression at once by the sensible tone of the preface, in which the gives some general counsels as to the proper way of dealing with the food of the sick

THE new number of the Journal of the Royal Hortscultural Society contains, besides extracts of proceedings, a number of interesting papers. Mr W Warren writes on Persian cyclamen; the Rev W Wilds on hardy cyclamen, Dr. M T. Mastern, F R S, on germination of ryclamen. Snowlings from the subject of papers by Mr. J. Allen, Mr. D. Melville, and Mr. F W Burbidge There are also papers on the cultivation of hardy bulbs and plants, by Herr Max Lechthia, Lachenaias, by Mr. F W Moore; Cape by Mr. J. O'Mien, and bybund Rhodoleathrous, by Yest.

The volume containing the Proceedings and Transactions of the Royal Society of Canada for 1890 includes papers on the American bison, by Charles Marr, the Vinland of the Northmen, by Sir Daniel Wilson; unit measure of time, by Sandford Fleming; a poculiar form of metallic iron found in Hutonian quartitie on the north show of Sir Joseph Island, Lake Huron, Ontaron, by G. C. Hoffmann; sun-spots observed at McGull Observatory, by C. H. McLeot; a test of Ewing and Mac-Gregor's method of measuring the electric resistance of electrolytes, by J. G. McGregor, the later physiographical geology of the Rocky Mountain region in Casada, by G. M. Dawson; fossil plants from the Simulkameen Valley and other places in the souther interior of Briths Cholmba, by Str. J. W. Dawson

MESSES SWAN SONNENSCHEIN AND CO will issue the following books during the autumn season -"The Colours of Animals," by Prof. Beddard, with coloured and other plates and woodcuts; "Text-book of Embryology Man and Mammals," by Dr. Oscar Hertwig, Professor of Comparative Anatomy in the University of Berlin, translated and edited from the third German edition (with the assistance of the author) by Dr E. L Mark, Professor of Anatomy in Harvard University, with 389 illustrations and 2 coloured plates; "Text-book of Embryology: Invertebrates," by Drs Korschelt and Heider, of the University of Berlin, translated and edited by Dr E L Mark, with several hundred illustrations, "Text-book of Animal Paleontology," by Dr. Thomas Roberts, designed as a supplement to Claus and Sedgwick's "Text book of Zoology," illustrated, "Text-book of Geology," adapted from the work of Dr. Emanuel Kayser, Professor in the University of Marburg, by Philip Lake, of St John's Col lege, Cambridge, with illustrations, "Text-book of Zoology," by Dr. C Claus, of the University of Vienna, and Adam Sedgwick, F.R.S., Vol. II "Mollusca to Man," third edition . "The Geographical Distribution of Disease in England and Wales," by Alfred Haviland, M.D., with several coloured maps, "Introductory Science Text-books"—Additions Introductions to the study of "Physiography," by H. M Hutchinson; "Zoology," by B Lindsay, "Amphioxus," by Dr B Hatschek, of the University of Vienna, and James Tuckey; "Geology," by Dr Edward Aveling, "Physiological Psychology," by Dr. Th Ziehen, of the University of Jena, adapted by Dr Otto Beyer, with 21 figures "Young Collector Series"-Additions "The Telescope," by J W Wilhams, "British Birds," by the Rev, H C. Macpherson, "Flowering Plants," by James Britten, "Grasses," by W Hutchinson, "Fishes," by the Rev. II C Macpherson, "Mammalia," by the Rev. H. C Macpherson

An instrument for optical comparison of transparent liquids, named a liquoscope, has been recently devised by M Sondén. of Stockholm Two hollow prisms holding the liquids are separated by a partition at right angles to the refracting angle. The whole is placed in a vessel filled with glycerine, and which allows of vision in a horizontal direction through plane glass plates. The deflection of the light rays through the prisms is thus compensated. So long as the two liquids have the same optical action, one sees a distant mark (say a black paper strip on a window) as a straight connected line; but its halves are relatively displaced if the liquids have different refractive power. The amount of displacement gives a measure of the difference. the positive or negative nature of which also appears from the direction of displacement The author recommends his apparatus for chemical purposes, especially comparison and testing of fats and oils, analysis of glycerine, &c., and detection of margarine in butter, margarine greatly lowering the index of

HERE HUPPERE has lately pointed out some of the biological bearing of the fact (observed in experiment along with Herr Albrech:) that long light-waves are much more strongly absorbed by water than short ones. If the lower marine animals had, like man, the livelest light preception with yellow rays, and a certain intensity of light were necessary to them, they must live at a less depth than if their visual organs were most strongly

NO: 1142, VOL 44]

affected by short-waved rays Thus, e.g., if they needed as much yellow light as that of the full moon, they could not live deeper than 177 metres (say, 590 feet). Yet they are found at all depths where food, oxygen, and a sustable temperature exist. On the other hand, the existence of plants having chlorophyll depends on light, and we might expect that the distribution of non-parasitic plants would be very limited, which is the case. no plant organisms being found under 200 fathoms. Green plants assimilate best in yellow light, and supposing plants to assimilate in moonlight they would find their limit at the above depth (177 metres). But while yellow is here weakened to 0 0000016 of its brightness, indigo blue has still 0 007829 of its original strength, and the assimilation with blue ravs will be 660 times as strong as with yellow Different coloured marine plants react differently according to the colour of light, and they have accordingly different distribution in depth.

The additions to the Zoological Society's Gardem during the past wesh include two Pinche Monkeys (Midu and sulpus 6 v) from Granda, presented by Mr. J. A. Atken; a. Fallow Deer (Chanas tudigares 28). British, presented by Mr. J. Donkson, a. Penian Gazelle (Gizella subgattivista 9) from Persia, presented by Baron Ferdinand de Rothschald, a. Common Commonan (Phalasecarea cardo), British, two Yellow-browed Bintings (Embersas crusted), a. — Banting (Embersas coulct), two Japanese Green inches (Pringila Sanarathis), ary 1 from Japan, purchased, a Yellow footed Rock Kangaroo (Petrogale vanthojus 9), born in the Gardens

OUR ASTRONOMICAL COLUMN.

THE LINEAR ARRANGEMENT OF STARE.—Although the arrangement of stars in curves has often been noted and studied, little attention has been paid to what is apparently a more arrangement of stars in curves has only parallel and parallel and an arrangement of the start of parallel and the start of the start

WOLF'S PERIODIC COMET.—This object can now be fairly seen by means of a small telescope. It will pass through the Hyades about September 25, and be 3 south of Aldebaran on October 2. The following ephemeris, from one given by Herr

Threen in Astronomische Nachruhten, No 3054, shows that the comet crosses the equator near the end of October .—

at the date of discovery (May 4) The maximum brightness will be reached about October 19

GEOLOGY AT THE BRITISH ASSOCIATION

THE Address of the President of the Coological Section having been devoted to the general questions involved in the origin, association, and working of coal, it was natural that the configuration of the configuration of

the coal exhaustive paper Mr. Togley summarized the chief the bearing on the origin of perturbenism. He pointed out that, while the American oil was mainly derived from Pialecupic Cock, that in Europe and Aua came largely from Secondary beets, and the large Caucasian supply was drawn from rock and the large Caucasian supply was drawn from rock apparent to be, a protest took, generally of sandstone or hime stone, which served as a reservoir and was underiam by or contained beds largely consisting of organic remains, with an impervious cover of shade. In many cases the insention has might be contained beds storing the gas and oil. Such rocks can contain from one-eighth to one-tenth of their bulk of oil. The oil was capable of storing the gas and oil. Such rocks can contain from one-eighth to one-tenth of their bulk of oil. The oil was drawn to the strate by artenian pressure, and so gas was drawn to the strate by artenian pressure, and so gas was drawn to the strate by artenian pressure, and so gas was drawn. Where the rocks were very highly disturbed oil occurred, thanks. Where the rocks were very highly disturbed oil occurred, but not in very great shordance, while gas was rarely found.

but not in very great souncance, waite gas was rarely found Mr Ross, in a paper on the same subject, endeavoured to prove that the oil was mainly generated by the action of solitatine volcanie energy upon beds of innestone, basing his conclusion on the occurrence of hydrocarbon and sulphurous vapours in solitatines, and the constant association of rock sait, follomite, and gypsum with the rocks yielding petroleum. He exhibited equations to show that the action of sulphur dioxide and sulphur retited hydrogen on carbonate of line, with or without water and peroxide of hydrogen, was capable of producing the chylene and maring gas derivatives, and equoted experiencis of Blachot to show that sulphur was formed by similar reactions, arguing that has hydrogen points in the control of the contro

to show that support was normed by similar reactions, arguing that the hydrocarbons must be necessary by-products Sir Archibald Geikie communicated two most important papers on the results of Geological Survey work in the Northwestern Highards One of these papers, relating to the discovery of the Olenellus zone in the North-west Highlands, was as follows :-- "Ever since the Geological Survey began the detailed investigation of the structure of the North-west Highlands of unswigation of the structure of the North-west Highlands or Scotland, the attention of its olineers has been continuously given to the detection of any fossil evidence that would more clearly for the geological horizons of the various vadiementary formations which overfite the Lewissa geness. A large collec-tion of organic remnant has been made from the Durieses time-stone, but it has not yet yielded materials for a satisfactory area graphable and the study of this collection, howstone, but it has not yet yeured materials for a satisfactory stratgraphical correlation. The study of this collection, however, has confirmed and extended Salter's original sagacious inference that the fauna of the Durness limestone shows a marked North American facies, though, according to our prevent terminology, we place this fauna in the Cambrian rather than in the Siluran system Below the Durness Imestone has the dolomitic and calcareous shaly group known as the 'Fucoid dolomitic and calcurous shaly group known as the 'Fucusd' beds,' which, though crowded with worm castings, has hitherto proved singularly deroid of other recognizable organic remains from the control of the control o It was struck with the singularly unaltered character of these shales, and acreed with him that if fossils were to be looked for anywhere among these ancient rocks, they should be found here, and that the food collector, Mr Arthur Macconochie, should be directed to search the locality with great care. The following week this exhaustive search was undertaken, and Mr. Macconochic was soon rewarded by the discovery of a number of fragmentary fossils, among which Mr B N Peach, who was also stationed in the district, recognized what appeared to him to be undoubtedly portions of Olenellus The importance of this discovery being obvious, the search was prosecuted vigorously, until the lossiliferous hand could not be followed sugrousty, until the institutions finant count not be followed further without quarrying operations, which in that remote makes the properties of the grant of the properties of the Geological Survey, who continued the reference to Olembia. More recently Mr. Peach interface the properties of the prop nrined the reference to totendus more recently sir. Feach and Mr Horne, in a renewed examination of the ground, have found, in another thin seam of black shale interleaved in the 'Serpulite grit,' additional pieces of Olmellius, including a fine head-shield with eyes complete. There may be more than one the head-spied with eyes compacts. The specific de-terminations and descriptions will shortly be given by Mr. Peach. The detection of Olenellus among the rocks of the North-west Highlands, and its association with the abundant Salterella of Serpulite grit, afford valuable materials for comparison with the oldest Palæozoic rocks of other regions, particularly of North America. The 'Fucoid beds' and 'Serpulite grit,' of North America. The 'Fucoid beds' and 'Serpalite grit, which intervene between the quartite below and the Durness limestone above, are now demonstrated to belong to the lowest limestone above, are now demonstrated to belong to the lowest part of the Cambrian system. The quartilect are shown to form the arenaceous base of that system, while the Durness insectiones may be Middle or Upper Cambrian. On the other hand, the Torridon sonadisone, which Murchaon placed in the Cambrian series, can now be proved to be of still higher anti-The marked unconformability which intervenes between than the overlying quarisate points to a long interval having elapsed between the deposition of the two discordant formations etapaed between the deposition of the two discordant formations. The Torndon sandstone must therefore be pre-Cambrian Among the 8000 or 10,000 feet of strata in this group of sand-stones and conglomerates, their occur, especially towards the base and the top, bands of grey and dark shale-, so little altered that they may be confidently expected somewhere to yield re-cognizable fossils. Already my colleagues have detected traces of sincelled and some more obscure remains of other organisms.

in these strata. These, the oldest relics of life yet known, have excited a vivid desire in the Geological Survey to discover further and more determinable fossils associated with them in the same primæval resting-place. We shall spare no pains to bring to light all that can be recovered in the North west High-

bring to light all that can be recovered in the North west High-nation of a pre-Combrain fauna. Two control of the Combrain faunal con-laints of the pre-Combrain faunal control of the North west Highland. "For some year past," for of the North west Highland. "For some years past," he remarked, "the officers of the Geological Survey have post much time and labour upon the investigation of the Post much time and labour upon the investigation of the post much time and labour upon the investigation of the post much time and labour upon the investigation of the They have succeeded in showing that it consust mainly of materials which were originally of the nature of enquive ignosis rocks, but which by a long succession of processes present No evidence of anything but such ensures rocks had have acquired ine compresses trincaters whose very more present. No videocc of anything hot such enjuryer tooks had present that the present the present the present that the present that the present that the present that the present the the timestones as the result of some crashing down and re-formation of basic ignous nocks containing lime-silicate. But as they proceeded in their work they encountered various diffi-culties in the acceptation of such a theoretical explanation. In par-ticular, they found that with the mica schi's were associated quarti-schits and graphitic achies; and that the limestone occurred in schits and graphitic achies; and that the limestone occurred in schists and graphitic schists, and that the innestone occurred thick and persistent bands with included minerals like those found in the Eastern Highlands in districts of contact-metamorphism. The microscopic examination of some of these rocks showed them to present close affinities to certain members of the crystalline series of the Lastern and Central Highlands, which can be recognized as consisting mainly of altered sedimentary strata (Dalradian series). Yet the officers of the Survey could not separate these doubtful rocks from the surrounding gness The several materials seemed to pass insensibly into each other in numerous sections, which were examined with great care Within the present month, however, one of the members of the staff, Mr C T Clough, who has been specially engaged in this staff, Mr C T Clough, who has been specially engaged in this investigation, has obtained what may prove to be conclusive averageston, has outsined what may prove to be conclusive submited of graphics chairs core every bedded in an acid mica-shirt, in which, also, thin graphics layers are distributed at intervals of an untoo relea. These rooks are sharply marked microbid to be a submitted of the state of the s evidence on the subject. He has ascertained that the main

to suggest the former existence of piant and animat itte.

The existion on Monday was opened by Sir K S. Ball with
a paper on the cause of an Ice age. The communication
stated that the author had a work in the press dealing with the
question of glacial climates. He had sevoed Herschel's figures,
on which Croll's deductions were based, and discovered an
arithmetical error of considerable consequence. If 63 repretents the number of beat-units received by any hemisphere
statis the number of beat-units received by any hemisphere sents the number of heat-units received by any hesusphere during ammers, its winter receive will be represented by 37. defining ammers, it winter received in 100 february to the position of heat may be received in 100 days or in 105 days, accounting the position of the espinones, producing either a long and cool summer or a short and intensely hot one. The paper day of the position of the winter producing either a long and cool summer or a short and intensely hot one. The paper day of the producing the paper serviced counterbule discussion, in which Frof. Sollas, Frof. Wright (of Oberlin, Obio), Mr. Hall, Dr. Crosskey, Dr. Hock, and many other gleatables took part. Forbes with regard to the glaciation of the Dovreffeld Wherever the basement rock is to be seen, it is glaciated, although moralnie deposits were swept away and redistributed by torrential action at the close of the Glacial period

Prof Wright read a most interesting paper on the Ice age of North America and its connection with the appearance of man in that continent. The glacial deposits, transported from several centres mostly outside the Arctic circle, and the absence some the cutter money dynamics that America cross also the address of the press of of a Polar ice cap, militated against an astronomical, and for a

Other papers read on this dity were one by Dr. Hicks, who produced specimens of boulders from Pembrokeshire, which seemed to him like North Welsh or Irish rocks—his picrite was, however, recognized as an Irish rock by geologists in the room, and in any case a flow of ice down the Irish Sea and over Pembrokeshire seemed to he clearly proved, one by Mr. Ken-dall, on a glacial section at Leven-hulme, Mnnchester, in which he gave evidence from the striation of the subjacent rock, and the intrusion of tongues of boulder clay into it, the transport of fragments, the orientation of large boulders, and the direction of strice, together with a consideration of the levels of the different portions of the rock beneath, that the district had been terent portions of the rock beneath, that the district had been travened by land toe coming from a direction of few degrees from Dailey Dale, near Matlock, which he regarded as having been washed out of rocks skring the valley. In connection with these papers may be mentioned a report by Mr. Harrison, who has excavated in the tails under some rock-shelters at Oldbury take securated in the status under ione for occasionists at Ordally Hill, near [abham, from which he obtained forty nine which finished Falicedithic implements and over 600 waste fakes, which were described in a separate paper by Frof Frestwich. Frof Wright gave also a brief account of the basilist laws beds of the Facilic tosis, which are of post-frestiary age. New evidence in favour of the gestimeters of the Calaveras skull and other human remains found under the law beds was given, and the discovery of a small clay image in a similar position under the western edge of the lava plains of Idaho at Nampa was re corded, the lava beds are correlated with the glacial deposits of

Mr Jones's report on the Elbolton cave, near Skipton, was of unusuat interest. Long-headed human skulls were found with burnt bones and charcoal in the upper stratum, associated with domestic animals and pottery ornamented with diamond and herring hone patterns; while at a much lower level—13-15 feet below the floor-there were round skulls, much more decayed. Delow the floor—there were round skulls, much more decayed, in connection with ruder and thicker pottery than has been found in any other part of the cave. No flints or metal of any kind have been found, and bone pins and other worked bones are the only human implements hitherto discovered. The are the only human implements hitherto discovered. The remains of bear and hare have been found in cave earth below this level, and the investigation is to be continued in the hope that remains similar to those of the Ray Gill fissure may yet be met with

An interesting discussion was raised on the paper by Dr. Hicks on the Silurian and Devonian rocks of Pembrokeshire

and Devon. The Silurian rests transgressively on Ordovician and pre-Cambrian rocks in Pembrokeshire, but is covered by and pre-Cambrian rocks in PembroVeshire, but is covered by a continuous rener su plin in he fold Reil Sandstone and Car-boniferous, similarly the Morte Slates, which the author regards as the oldest rocks of North Devon, and in which he has recently found Linguilla Durssis, are covered by the Devonian and Culim sense of rocks. Mr. Ussher described the occurrence of a volcanie series in the Lower Devonian rocks of Tor Cross, and traced similar disbasic rocks amonest the chloritic series of Prawle Point, the excessive alteration of these rocks being due to the greater nearness to the old resisting rocks of the Channel In this conclusion he was supported by Mr Hunt, who described the occurrence of detrital tournaaling In the Devonian cliffs at the north-east end of Straiton Sands. and compared it with the occurrence of similar material in a quartz-schist west of the Start Lighthouse. Both schists and sandstone contain detrital tournialine, mica, fine grained quartz, and iron

and iron
Several palaeontological papers were contributed Mr
Montagu Browne exhibited teeth, scales, and boncs of Colobodus from Aust, Warchet, and Lencettershire, which seemed
to indicate the identity of Colobodus with Lepidotus, and possibly of Heterolepidotus with Eugnathus, and to give Colo-bodus an extended upward range Mr Buckman gave an account of the Ammonite zones in the Inferior Oolite There is a marked break on the Continent between the Murchtsone and a marked break on the Continent between the Muchtsonse and the Soverbyz zoncy, which appears to be filled up by the zone of Listers concatum in England The Soverbyz zone, however, is absent in England from all localities except Fundity, and Coombe near Sherborne, and the author therefore 'cought and chiamed a grant to open an old quarry at the latter locality, in order to fully investigate the fauna of the Soverbys rone, and its relationship to the concavum and Sauzes zones Mr Storre, of the Cardiff Museum, exhibited a fine series of slides and drawings of Pachytheca and Nematophyeus, and gave a minute description of them , this elicited some discussion, in the course or writen Mr Marray suggested the Mr Merray suggested the before might possibly be the egg of a Cristicent or one of the Corner might possibly to the egg of a Cristicent or one of the Mr Smith Woodward completely incrusted by a Nullipore. Mr Smith Woodward and gave an account of series of Miocene fish-remain from Sardina Other paleonous Donce fish-remain from Sardina Other paleonous Other paleonous Donce in Sardina Other paleonous Other paleo gave an account of a series of Miocene fish-remain from Sar unna Other paisonological papers were one containing a form of the series of the series of the series with the the Lower Keuper building stone of the series with the series and one by Mr. Vine on the Brycono of the Upper Chalk. Mr. B Thompson gave an exhaustive report of the transition bed between the Middle and Upper Lias in Northamptonshire, from which he had obtained a large and valuable series of fossils Mr Newton described the occurrence of *Ammunits purents* in the Northampton sands, near Northampton; and Prof. Hoyes Panton gave an account of a matedon of very large size at Highgate, Ontario, and a mammoth from Shelburne, in the

The occurrence of a strip of Lower Greensand four to five miles long hetween Shaftesbury and Child Okeford, and running parallel to the valley of the Stour, was described by Mr Jukes Browne The same author attempted to explain monoclinal flexure by the recurrence of movement in rocks already faulted, but covered subsequently by unconformable strate; movement along the faults of the older series, under the influence of new pressure, would throw the overlying series into monoclinal folds or faults. The existence of a large area of Kellaways rock, near Bedford, and the extension of Fuller's earth works at

near Dectord, and the extension of Fullers-earth works at Woburn were commented on by Mr Cameron Several of the Committees appointed last year had done good work. The Photograph Committee had obtained over 250 new photographs of geological interest, many of which were exhibited in the Section-room or at one of the sowiers, where also Prof in the Section-room or at one of the source, where also Prol Wright displayed a fine serice of transparencies illustrating the lava and glacial deposits of the United Stotes, and Mr. Stirrup a set of slides of the dolomite district of Languedoc. The Earth-Tremor Committee had been testing a number of record-Earth-fremor Committee had been testing a number of record-ing instruments; Mr. Smith Woodward reported that the lists of type specimens were progressing, and that many large Museums were publishing their own lists of types, Mr. De Rance gave an account of a number of wells in Yorkshire, Lingave an account of a number of wens in toussing, and recognishing, Notts, Cheshire, Shropshire, and Glamorganshire, and Mr. Johnston-Lavis sent a description of the Vesuvian eruption of 1890-91, the chief part of which has already appeared in the columns of NATURE.

RIOLOGY AT THE BRITISH ASSOCIATION

THE papers read at this Section were fully as interesting, though not quite so numerous, as usual. A good deal of time on one day was occupied by a discussion upon animals and plants, but as several of those who took part in the discussion did not wish their remarks to be reported, it has been thought better to leave out this part of the proceedings of Section D. Botanical papers preponderated over zoological, but it was not found necessity to divide the Section into two

sub Sections. sub Sections.

Mr Grenfell read a paper upon the structure of Diatoms, describing pseudopodia in these organisms. The pseudopodia are quite easy to see in such a form as Melostra with even a are quite easy to see in such a form as Metorica with even a comparatively low power. They are very long and stiff, radiating outwards from the periphery, and are apparently non retractile (they were watched for an hour without any movements being observed), the pseudopodia are sometimes nine times the length of the diameter of the Diatom, and are occasionally branched, adjacent Diatoms were sometimes seen to be connected by a fusion of their pseudopodus. It was suggested that the use of the pseudopodus is to keep the plants floating, and to act as a protective cheveux de frese against their These Diatoms were compared to Heliozoa, with en unes These Diatoms were compared to Itelioroa, with which they have evidently not a little resemblance in the form of the pseudopodus Incidentally Mr Gienfell stated that he half found a conting of cellulose upon the green corpuscles of Archema, which were regarded by Jankister as chlorophyll

bodies, and not as symbiotic algre,

Mr Wager described the presence of nuclei in Bacteria, they were met with in a species of Facillus found in water containing

decaying Sproggra a species of matinal touch in water containing decaying Sproggra a paper upon the nephridia of the leech, McMidis. The citated funnels appear to love their connection with the rest of the nephridium, and to perform the function organs for the propulsion of the blood along the channels in

which they be
The Plymouth 700 logical Station sent a record of work done
Jurnag the last year by the Director and by Mr. Cannagham.
Mr. Calder-root dreaf a paper upon some conformation
Mr. Calder-root dreaf a paper upon some conformation
the conformation of the state of t had already been made towards a satisfactory solution of this difficult problem. Inquiries were also being conducted with regard to the occurrence of anchowes on the south-west coast of Fugiands, and Mr. Cunningham, the Naturalist of the Association, had carried out some inquiries at fishing viations on the south-coast. At present no net small enough in the mesh to apture anchowes were employed, but that fish appeared so often when the ordinary juliciard nets became entangled, as to suggest when the ordinary pulchard nets became entangled, as to suggest that they might be present in considerable quantities. Anchowy nets had, therefore, been constructed, and would be used during the pilchard servon this autumn. An investigation was also being carried on into the condition of the North bea fisheries, which were declared to be rapidly declining. It was proposed to draw up a history of the North Sea trawling grounds, comparing their present condition with their condition some twenty or thirty years ago, when comparatively few boats were at or thirty years ago, when comparatively few boats were at work; to continue, verify, and extend observations as to the average sites at which prime fish, such as soles, turbot, and brill, become sexually mature, and to collect sixistize: as to the surse of all fish captured in the vicinity of the Dogger Bank and the region Jugic to the eastward, so that the number of imma-ture fish annually captured may be estimated. Also to make experiments with beam traval nests of various methos with a view. the size of fish taken Mr Calderwood added that a regular to determine the relation, if any, between the size of mesh and the use of fish lakes Mr. Gliderwood sided that a regular survey of the English Channel had been commenced, not only in station of the second order had been recently established, where observations at 9 c.m. and 9 p.m. would be taken daily by wet and dry bulb theremoetters, bornetters, rana-gauges, and aum.

and dry bulb thermometers, barometers, rain-gauges, and sun-chine-recorders.

Mr. J. T. Cumingham read a paper upon the reproduction of the pilchard. The ovum of this fish, described as such in the Journal of the Association for 1889, was stated by Fouchet

not to belong to the pilchard; Pouchet believed that the pilchard's ovum is not pelagic. The identification of the ovum was shown to be correct by further observations carried out in the Laboratory with the ova obtained from the mature fish Similar results have been obtained by Marion, of Marseilles

senies
Another paper, by the same, dealt with the growth of foodfishes, and their distribution at different ages
(1) Acts of Crowth and Sey of Sexual Mediurity —Numerous
specimens of the flounder (Pl flux) were reared from the larval
shall to the aground of the Plymouth Laboratory Measured state in the aquarium of the Plymouth Laboratory Measured in April, when a year old, they varied from 4 to 19 cm. (about 14 to 74 inches) Specimens obtained in the Catlewater, and known to be not less than a year old, are from 12 to 19 cm in length. None of these captive flounders, nor any taken in the Cattewater, were sexually mature, but, according to Dr Fniton, of the Scottish Fishery Board, sexually mature flounders have been observed which were only 7 inches long. It was concluded, therefore, that (a) the rate of growth varies greatly for different individuals, but its maximum for the first year is 19 cm, or 7½ inches, (b) sexual maturity is not reached till the end of the second year, although the minimum size of sexually mature individuals may be slightly exceeded by some specimens in one year's growth

Sumilar results were obtained for the plaice (Pl platessa) and

Studies results were obtained for the place (F flatten) and the dab (F) insurant-The young of the above-mentioned species (3) Distribution—The poung of the above-mentioned species (3) Distribution—The studies of the second of the studies and G manufact, occur in about first, see the studies and G manufact, occur in about first see the studies and G manufact, occur in a bottom of the studies and G manufact, occur in a studies o do not pass the first year of then lives in shallow water do not pass the first year of then fives in shallow water. Young soles in the larval state occur in total pook at Meyagwey, and young turbol and brill z to 3 cm in length are commonly found young turbol and brill z to 3 cm in length are commonly found with the state of the stat shallow water, and apparently live at depths greater than 10 fathoms. It seems that our commoner and more valuable food fishes do not attain to sexual maturity till the end of their second

fished to not attain to sexial maturity till the end of their second year, that their near at this age is subject to great midwidual variation, and that the young in the first year of growth have a form they not it of view is now being carried on a Plymonth. The distribution of Orytallogolus Wilson was recorded by the same author. It had been found by Collett in the Planting Collett in the carried on the property of the proper waters—one taken by Indina Edwards in a rock pool at sann.
Mr. Holt subsequently dredged a number in 30 fathoms in
Ballinskelligs Bay The species is probably fairly abundant
between 20 and 30 fathoms on smooth sandy ground all along
the British and Irish coasts.

Mr Cunnipham also read a paper upon the larve of the sea crayfish (Philmurus vinicurs), describing most of the stages, and particularly remarking upon the presence of the first maxili-pede in the newly hatched larva, which had been stated by Richer to be absent.

Prof Herdman and Mr. J A Clubb communicated a paper upon the innervation of the epipodial processes of some Nudibranchiate Mollusca. The cerata of the Nudibranchis were regarded by Prof Herdman as being probably epipodial out-

growths.

The question has, however, been raised lately by Pelaeneer and others as to whether the so called epipodia of Molliusca are all homologous structures, and one of the subjects of controversy now is the origin of the nerve supply in various forms, it being and a the origin of the nerve supply in various forms, it being supposed that where the processes are innervated from the plenral ganglia they are pallial in their nature, and where supplied from the pedal ganglia they are to be regarded as quigrowths from the foot.

Consequently it seemed of importance to determine afresh the origin of the nerves supplying the cerata in several different types of Nudbranchiata, especially as the results of former investigations, depending entirely, we believe, upon minute disvestigations, depending entirely, we believe, upon minute dis-section, are puzzling, and to some extent contradictory. We have traced the nerves from the ganglia, by means of serial sec-tions, in representatives of the genera Polycera, Ansula, Tritoma, Dentironolus, and Eolis, with the following results:—

In Polycera quadrilineata the cerebral and pleural ganglis are completely fused to form a cerebro pleural mass. The "epipodial" nerves are foand arising from the ventral and posterior part of this mass (i.e. distinctly from the pleural ganglia), and they run along the sides of the back to supply the

certaial ridges
In Ancula certata the pleural ganglia are fairly distinct from the cerebral
In a specimen cut into about 500 sections we find in the 100th section or so from the anterior end six distinct ganglia (the cerebral, pleural, and pedal pairs) surrounding the cerebrals. A few sections further back, the cerebrals disappear, and then the epipodial nerves are found arising from the pear, and then the epipodial nerves are lound arising from the dorsal edge of the pleural ganglia. The nerves soon turn posteriorly, and then give off their first branches dorsally. These branches enter the mesoderm of the body wall, and can then be traced back through over a hundred sections to the first pair of cerata, which they enter The main nerve passes back to the remaining cerata

to the remaining cerain In Titoma and Dendronolus also the epipodial nerves arise from the pleural ganglia, but in Eolis (or Facchina) coronata we find that the main nerves to the cerain arise distinctly from the and that the main nerves to me certain arise unitarity from the pedal ganglia. We have also traced in the same series of sections the ordinary pedal nerves to the foot proper, so there can be no question as to the nature of the ganglia from which the nerves arise The epipodial nerves spring from about the middle of the pedal ganglion, rather on the dorsal surface, and after a short course, pass through the miscular layer of the body wall and are distributed to the clumps of ceraia

But, in addition to these main epipodial nerves in Eclis, we find also a nerve arising from the compound ganglionic mass, immediately ventral to the eye (probably, therefore, from the pleural element), which goes to the front cerata. This pleural nerve has its origin distinctly anterior to the origin of the main epipodial nerves from the pedal ganglia

We arrive, then, at the curious result that the innervation of the entry tree, at me curious result that the innervation of the entry tree is the entry tree in the e visible nerves from the pletrait. In the ordinary Rhippide glossate Custroped, und as Trecken, the eppodard radges and processes are supplied, according to Pelenere, by nerves arrange meaning to the choice of the pleaf gangla, So, pademon from the area to the choice of the pleaf gangla, or from the area of the choice of Father as pelad in there nature, and homologous with the eppodal efforces so I I rich site, which twose of Janeda and the rest are totally distinct structures of pullud origin. But these down clared processes in the various Nutritionals are so much alike in their relations, and are connected by such series of gradations, that it is difficult to believe that they are not all homologous, and the presence of the accessory epipodial nerve in arising from the pleural ganglion suggests the possibility of another explanation, viz that these outgrowths, starting at first as pedal structures innervated by nerves from the pedal ganglia, niay have acquired, possibly as the result of having moved further up the sides of the body, a supplementary nerve supply from the adjacent integumentary nerves arising from the pleural ganglia, and this supplementary supply, while remaining subordinary in Eolis, may in the other types have gradually

subordinary in Zotts, may in the other types have gradually come to supplant the original cipyloidal nerves, which are now no longer found in such forms as Polycera and Ancula. This is a present only a suggestion, which may be disproved or supplant of the common than the casimisation of the nerves of a number of additional No. Parker read a paper containing the results of some experiments on respiration in the tadpoles of the common fore,. After referring to the great power of adaptation to external conditions seen amongst amphibious larves, the author conditions seen amongst amphibious larves, the author described some experiments on for gradpoles, which, thhough no described some experiments on for gradpoles, which the complex of the supplements of the common forestimal parts. In tadpole measuring more than a can.

in length—the gills are no longer sufficient for purposes of re spiration, and the animals die in a very short time if prevented from coming to the surface to breathe (2) If tadpoles are prevented from using their lungs from an earlier stage onwards, the gills remain perfectly functional, and development proceeds as usual. At metamorphosis, the fore-limbs are slow in become as usual. At metamorphosis, the fore-times are slow in become ing free, owing to the retention of the operation, that on the same side as the spiracle appearing first. Eventually, a slit like same sade as the spiracie appearing first. Eventually, a slit like spiracie is present on either side. In respiration, the mouth is opened and closed, as in the tadpole. Specimens of branchiate frogs were exhibited, in which the tail had shrunk to less than half its original length.

Exhibition of, and remarks upon, some young specimens of *Echidna aculeata*, by Prof W N. Parkei The specimens are from the collection of the late Prof W K Parker, cimens are from the collection of the late Prof W K Parker, who received them from Dr. E. P. Ramas, Curaiu or feet, who received them from Dr. E. P. Ramas, Curaiu or feet, the restral vide, the anous pointing betekwards, and the rot, the veetral vide, the anous pointing betekwards, and the rot, in the older of the two stages, forwards The youngers stage measures along the dorsal curve, from the end of the snost to the tip of the tail, 12 cm., the greatest diameter of the body being 3 cm., the corresponding measurements of the older stage are respectively 21 5 cm and 6 cm. In the latter, the body is covered with short scattered birsiles. In both stages the shout is very similar in form to that of Orinthockins, and is covered by a thick horny layer, but in other respects the specialization characteristic of Lehidna is already apparent The gape is narrow, and extends only a short distance down The gape is narrow, and extends only a snort divance own-the snow, and the manue, even in the younger stage, is already much larger and stronger than the pes. The tail is short and conical. There is no caruncle, or "egg-breaker," in the snout, such as is seen in Orntho hymotus. A few points in the structure of the fore part of the head in the older stige were described The mouth has the narrow and tubular form seen in the adult, and the long tongue has a horny tip The glands in relation with the mouth and nose are very numerous There is no trace of any teeth-rudiments, and in many other respects the structure of the head shows extreme specialization Jacobson's organ is large, and highly developed A well-marked "turis present in it

Prof Howes read a paper upon the classification of fishes by their reproductive organs. On comparison of the mino gental organs of those Osteichthyes having a non abbreviated kidney with the same organs of the higher Vertebrata and the Elasmobranchs, the female gental duct and the kidney are seen to be orances, the temale genital duct and the kidney are seen to be inversely proportionate in length. No feature more fully characterizes the development of the Mulletian duct than the ac-companying abbreviation of the kidney and the disappearance of its head segment. The persistence of the last named among the Osteichthyes, and its possible retention of the renal function in rare cases, taken in conjunction with the mode of development of the ovary duct in these fishes, point to the conclusion that the latter is in no way homologous with the Mullerian duct as ordinarily understood Balfour's belief that the genit il ducts as ordinarily understood Dallour's nellet that the gent it ducts are homologous in both sexes of the Teleosteans, is supported by the facts of anatomy, and comparison of the reproductive system of the Gancids with thu of the Teleosteans shows the two to be modifications of the same common type, and the absolute structural community of the parts in the males and females of the Sturiones, while further confirming Bal four's doctrine, is opposed to Jungersen's implication that the subtle differences in the mode of development of the ducts in the opposite sexes of the Teleotter, are indicative of their non-homology. The facts above alluded to justify us in their non-homology increases above and entry us in regarding the genital ducts of the Osteichthyes, not only as homologous in the two sexes, and primarily independent of the genital glands, but as distinct structures in general, probably unrepresented in all other Vertebrates. The Plagiostomi and Holocephali, in which vasa efferentia are present and the kidney becomes an accessory to reproduction in the male, may be grouped together into a Nephrorchidic Series, as distinguished from an Enthorchidic Series, embracing the Canoids and Teleosteans. Comparison of the port genitales in relation to the parts of the females of those Teleoster destitute of genital ducts, parts of the females of those Leleosic destitute of gential ducts, especially in consideration of the facts concerning the development of the parts recorded by Scott, Liszt, and others, supports Rathkie's conclusion that the ancestors of the former fishes must have possessed gential ducts the Catechthyes, sithough specialized in respect to many features of their organizations, have,

together with the Marsipolaranchs, retained the least modified type of unnogenital organs known for fiving Vertebrates. W Parker's recent and important discovery that, while in Protopterus a Mullerian duct is present, vasa efferentia are absent, and the testicular products are discharged through a duct ansent, and the testicular products are discharged through a duct more nearly comparable to that of the bony fishes than to the gential ducts of any other Vertebrates, suggests that the deve-lopment of vasa efferentia and the assumption of a genital func-tion by the Wolfman duct, may have been effected subsequently to the formation of the Mullerian oviduct And further comparsion of the Dipnor with the Elasmobranchii suggests that the former may have struck off from the Holocephalic branch of the latter before the differentiation of the ancestors of its living me mhere

Another paper by Prof Howes dealt with the customary methods of describing the gills of fishes. The gills of Plantostomes and Marsipobranchs are not unfrequently enumerated in relation to the opposite walls of the visceral sacs which give origin to them, while those of the higher fishes are enumerated In telation to the opposite faces of the septa which bear them. The confusion arising out of this is well known to teachers, and is, in itself, sufficient to justify the introduction of a revised nomenclature for the parts concerned The facts of develop-ment show (1) [on the assumption that the mandibular or month cavity is serially homologous with a pair of post-oral visceral elefts] that cach gill lies in front of its corresponding visceral eletis) that the saccular type of gill met with in the Maisipobranchs and Plagiostomes is that from which the pecinnte one of the higher gnathostomatous fishes has been derived, and (3) that a mandibular gill has no existence in hving fishes and (3) that a mandibular gill has no existence in living fishes fulls of the Marsipohinuch-Plagiostome type may be conve-nently described for general anatomical purposes, as Cytin-branchia, and those of the higher Telosteout type, as Petitin-branchia, while the parts of the individual gills themselves should be in all cases enumerated in relation to the visceral should be in all cases enumerated in relation to the viscerial pseudost from which they are. I has, the spiracular gill of Lisamobianch folders termed the mandibility pseudostanching [1] of the higher fishes (often termed the hyord pseudobranch) as the first hranchial hemilitanch. The well known screes of hoccal filaments met with its certain. Chelonia appear to have noccal manners met with its certain Chetoma appear to nave we fit the fundamental relutionships of gill flows, and, in view of the appear, from its mode of development in the Telesate, to be the morphological equivalent of a pair of gill pouches, the possibility that these filaments may fit any rate for the most party represent mandhular gills of inversional character must not be overlooked

Dr Arthur Robinson communicated some facts relative to the development of the rat and the mouse. The most important put of the paper dealt with the relation of the yolk sac to the part or one paper dealt with the relation of the yolk sac to the maternal tissues. The crypt in the uterine wall which lodges the own hecomes shut off from the rest of the cavity of the uterus by a fusion between the distal proximal walls of the sterus. The greater part of the space so formed is occupied by the own, the renaming portions are converted in occupied by the own, the renaming portions are converted into material blood sinuses, the blood in these sinuses baths the trophoblast and the distal end of the yolk sac. Later, the distal part of the yolk cavity is obliterated by the apposition of its walls, but the proximal portion remains, diretticula grow out from from this into the placenta, which inauntain the intimate relation of the solk sac to the maternal blood It seems probable, in view of these facts, that the yolk sac plays an important part in the nutrition of the fectis. The allant is is a solid mass of meso blast containing no diversiculum from the elimentary tract, and does not become attached to the trophoblast until comparatively

does not become attached to the trophosomer and companions, late in the life of the embryo, i.e. the eleventh day

Another paper by the same was entitled "Observations upon the Development of the Spinal Cord in Min minimum and Min.

The control of the Spinal Cord in Min minimum and Min. decumanus the Formation of the Septa and the Fissures accuments the Formation of the copy has and the Fishers." The anictron and posterior septs of the cord west saled to be formed by the spongoblasts of the cord stelf, and not by ingrowths of the enveloping shealth of pia mater. Prof. Marcus Hartog communicated an outline classification of sexual and alluel modes of protoplasmic repuvenescence.

- I The following modes of rejuvenescence occur in cellular and in certain apocytial organisms -
- A. PLASTOGAMY the fusion of evtoplasta into a plasmodium. the nuclei remaining free

- B. KARYOGAMY · the union of cells (gametes), cytoplast to cytoplast and nucleus to nucleus, to form a 1-nucleate cell, the zygote The following variations occur:
- I ISOGAMY. The union of gametes undistinguishable in size, form, and behaviour; this may vary as follows -
 - (a) Mill TiPLE · between several gametes (up
 - (4) BINARY + between a pair of gameles :
 - or, from another point of view-
 - (c) Indifferent between any gametes of
 - the species (d) Exogamous, between gametes of dis-
 - tinct broods only
 (c) Endogamous between gametes of the same brood only
 - ANISOGAMY · the union of two gametes differing
 chiefly in size, the smaller (mero) gamete is
 male, the larger (mega-) gamete, female.
 HYPERAINSHAMY: the female gamete, at first
 active, comes to rest before fusion with the inale
 - OGGAMY: the female is never actively motile, the male is termed a spermalosoon, the female an nosthere

From another point of view karvogamy is-

- 5 ZOOIDIGGAMOUS one gamete at least is actively
- motile (flagellate, ciliate, or amosboid)
 6 SiPHONOGAMOUS karyogamy is effected by a
 tubular outgrowth from one or both of the gametes
- II In apocytial fungi multinucleated masses of protoplasm (gametoids) may conjugate to form a zygotoid, by a siphono gamous process. The union may be trogamous or anisogumous.
 - III. Gametes may be classified as follows -
 - A According to their formation-
 - I EUSCHIST . formed by repeated complete divisions from a parent cell, the gametogonium

 - (a) EUTHYSCHIST each nuclear division is accompanied by cell division (b) Bradyschist the nuclear divisions are completed before any cell division takes place
 - (c) Isuschist . the brood-cells of a gametogonium are all equal and functional,

 (d) Anisoschisi the brood cells are unequal
 - some of them being reduced to aborted or degraded gametes

 - 2. HEMISCHIST: the divisions are limited to the nucleus, none occurring in the cytoplasm.

 3. APOSCHIST: the cell divisions do not occur, but a cell directly assumes the behaviour of a
 - gamete
 4. SYMPHYTIC: the gameto nucleus is formed by the fusion of several nuclei
 - B According to their behaviour, as-

 - FACULTATIVE: retaining the power of development if karyogamy fails to occur
 OBLIGATORY: with no power of independent development.
- 1 Va. PARAGENESIS will include the following modes, usually grouped ander the term parthenogenesis, apogamy (pro parte), &c 20
 - A TRUE PARTHENOGENESIS: the direct development of a
 - facultative gamete without karyogamy (1) Isogametes; (2) Anisogametes (male and female);
 - (3) Oogametes. NO. 1142, VOL. 44]

- B. SIMULATED PARTHENOGENESIS -
 - I CELIULAR: a cell assumes directly the behaviour
 - of a rygote.

 APOCY FIAL a multinucleate mass of protoplasm assumes directly the behaviour of a zygotoid.
- C METAGAMETAL REJUVENESCENCE :-
 - 1 UNICFLULAR: a single cell in the neighbourhood of the gamete assumes the form and behaviour of the zygote.
 - 2. MULTICELLULAR · a mass of cells in the position where gametes should be produced, assumes the character of the young organism formed by the zygote
- D PARAGAMY or ENDOKARYOGAMY · vegetative or gametal nuclei lying in a continuous mass of cytoplasm fuse to form a zygote nucleus
 - 1 Progamic paragamy, the fusing nuclei are the normal gametonuclei of the progamous cell (ovum which has formed 1-polar body)
 - 2. Apocytial paragamy the vegetative nuclei of an apocytium fuse to form a zygote nucleus.

The President of the Section read a paper by himself and Miss Dorothea Pertz, on the artificial production of rhythm in plants. The apparatus, devised by the Cambridge Scientific Instrupiants, aneapparatus, devised by the Cambridge Scientific Instru-ment Company, was exhibited. The plant is subjected to a subject of a less of alternate and opposite influences from light or gravitation, as the case may be The plant to be experimented with it fixed to a spindle, which, by a clockwork escapement, makers a sudden semi-reduction every half hour. When the clockwork staded semi-revolution every hall hour. When the clockwork is stopped, the plant continues to curve with an acquired rhythm; as if the machinery were still in action. This is similar to certain natural rhythms—for instance, to the "sleep" of flowers, which for a short time continue to open and shut although kept

onstantly in the dark

Prof Green read a paper on the occurrence of disatase in
pollen The starch in the pollen grain serves as nutriment for
the growing pollen tube, and the presence of the ferment
converting it into sugar enables it to travel along the growing tube

Prof Vines, in a paper upon diastase in foliage leaves, con-troverts the opinion of Prof Wortmann, who stated that diastase was either absent from the foliage leaves of plants, or present in such minute quantities that it could be of no physiological im-portance. It is this distastes, and not the protoplasm of the cells, which converts the starch accumulated in the leaves into sugar.

Canon Tristram exhibited and made remarks upon the smallest known species of parrot, of which the skin measured only two inches in length.

THE CONGRESS OF HYGIENE

WE printed on August 20 (p. 303) an account of some of the work done in the Section of Preventive Medicine in the Congress of Hygiene The following 11 the conclusion of our

A COROTICA

Sir Dyce Duckworth, of London, opened a discussion on "The Relation of Alcobolism to Public Health and the The Relation of Alcobolism to Public Health and the Prof. Health Wastergaard, of Openhager, followed with a paper on the same subject. What are the losses of life, he saked, caused to a population by intempenace? This question can to a certain extent be answered by examining the causes of death, in the same of the cause of th objected that these causes of death supply an unsatisfactory picture of druking excess, because the wish to spare the feelings picture of annixing excess, occases the wish to spare the teetings of surviving relatives maker returns of such detable less tristi-worthy, and it has therefore been proposed to use other diseases as a measure—such as liver diseases (especially circhess of the liver). Yet it is worth while to examine the above-mentioned causes of death. In most countries the satistices of the cause of death do not allow conclusions with regard to alcoholism corre-sponding to those for Denmark and Norway. But, at all

events, the statistical data sufficiently show that a great part of the civilized world is suffering greatly from the effects of alco-holism. The investigations of the Harveian Society make it tolishis. Like introduction to the Christian Society Make and analysis and females) is directly or indirectly due to the consequences of alcohole excess. The mortality in England from alcoholism in 1871-80 among males 23 to 65 years old was about 1 per cent of all desthan-nearly 800 yearly. What an amount of represented by these 800 destalt 1. In ledguen the yearly loss of life from delinum tremens among males was 330 in 1870-89 Still greater have been the devastations of drinking in Switzerland Prusias has a yearly loss of 100 males from delinum could be had, that chronic alcoholism and delirum tremens alone kill many thousands of men every year. What is to do done? High excess are generally looked upon as an excellent weapon against alcoholism. But we must not forget be done? High excess are generally looked upon as an excellent weapon against alcoholism. But we must not forget properties of the state of the stat probable that in London one-seventh of all adult deaths (males iong as the number of public-houses it so exceedingly inage as in this country. If a person has to go a long way to get drunk, and if he has in addition to pay a good sum for it, he will stop to think before going. Still, high access seem to have some effect, the Verman law of 1887 has, for instance, reduced the con-sumption of spirits to a certain extent. But generally the reduction of the consumed quantity does not seem to correspond with the increase of the excess. An interesting expellent is to new State monopoly in Switzerland. Ten per cent of the surplus are left to the cantons for counteracting alcoholism. regulating the price the monopoly acts like an excise, and the Government takes care that only unadulterated liquors are sold The monopoly is reported to have had a good sanitary effect, and it has caused some decrease in the consamption of liquors. In connection with excise and duties every effort is to be commended which tends to render the access to intoxicating liquors more difficult. Among these measures, the three popular American systems deserve our attention—viz the Maine laws, American systems deserve our attention—viz the Maine laws, local option, and the high-inence system the first of these expedients—the prohibitory system—has been tirted in Maine and some other American States According to this system, it is prohibited to manufacture and sell intoxicating liquors, the only exception commonly being that liquors of "foreign production" may be impurited and sold in the original packages. But this exception is unjust, permitting the man who can afford it to order as much inquere as he inkes, and nearly air reports agree in testifying to the perpetual violation of these law. One curious fact from Maine, where the system was adopted in 1851 may be mentioned During the years 1867–86, 8412 divorces of marriages took place, being profinably several per cent of the yearly number of celebrated marriage. Of these no less than years number of cereorated marriages. Of these to less than 960, or 11 per cent, were caused by intemperance, combined or not with other causes. It thus seems that intemperate habits are rather frequent in this State. Curiously enough, the State of Massachusetts (where there is a considerable revenue for of Massachusetts (where there is a consucrable revenue for licences) shows, under nearly the same proportion—viz 1654 out of 9853. It seems impossible to suppress the liquor traffic in the larger towns. Between the Maine laws and the in the larger towns. Between the Maine laws and the high-incence system is an intermediate system—local option. According to this, it is left to the citizens of a village of the control of the citizens of a village of the citizens of the to a sereptitions lipnor traffic. The third system—high licences—has been introduced in several States Under this system licences for the sale of liquors can be taken out, but the fees are to considerable for instance, too or 100 olollary serably that many small saloom disappear. In some cases the sale of liquors many small saloom disappear. In some cases the sale of liquors many small saloom, the sale of the sale of liquors and the sale of the sale of liquors and the sale of the sale of liquors and the sale of the s

limit the numbers of lucroes that may be taken out. This is the case with the Dutch has of 1881. Still more effective have been the efforts in Sweden, Norway, and Krisland. The numbers of hars have been gradually greatly reduced, especially in the rand districts; and in most of the towns the so-called. "Gothern and the control of the towns the so-called "Gothern and Control of the control of the towns the so-called the Gothern and Sacd rate of interest to the shareholders, the simple and the same and the sa

prote the body towards the attacks of disease generally than to miduce any special pathological lesion

M. Milliet, of Berne, Dr. Norman Kerr, of London, Mr. J. Phillips, of London, Sir V Barragion, L. C. G. Dr. Robinson, of Mance, U.S. A., Sir Joseph Fayrer, Prof. E. Alglave, of Paris, Dr. Kinkead, of Galway, Dr. Arthur, of London, Prof. Bohmert, of Dersden, and Dr. Sonsino, of Pisa, alto took part in the disease.

On Thunday afternoon, Dr. W. O. Pricatley read a paper "On the Improved Hypener. Condition of Materiaty Hospitals," of which the following is an abstract — During the end of the last century and the first half of the present one, the mortality in materiaty hospitals was very large, both on the Continent and in Great Britain: According to Le

During the end of the last century and the first half of the special cost, the mortality in materially hospitals was very large, special cost, the mortality in materially hospitals was very large, special cost, and the cut of \$2 \text{ per roco}, while, according to Miss Per 1000, equal to 1 in 132. The cause of the increased mortality in lyng-in hospitals was the prevalence in these most continuous proposition of the cost of the cost

results. Hence it came to be recognized that, by preventing the ingress of these germs to the bodies of puerperal patients, compartive safety, even in lying-in hospitals, was attainable; and the introduction of the anusepite and aseptic methods has produced not only a remarkable diminiution of mortality, but also of duced not only a remarkable diminution of mortality, but also of the morbidity or illness undent to the puerpent slate. A short of the morbidity or illness undent to the puerpent slate. A short countries to lawure the greater safety of patients in maternity hospitals, and of the results obtained in Europe and not United States. The results were very artiking, and were attributable to the control of the country of the countries of the con-trol of the countries of the countries of the countries of the restatent, although other improvements are not has ught of in concluding the citild attention to an interesting table in which were thrown together the statistics of material deaths in six lying in hospitals, situated in various countries, since the introduction of aseptic or antiseptic methods. With these he had contrasted the figures of M. Le Fort before the era of antiseptics, and Mr Newbatt, the distinguished President of the Statistical Society, had kindly computed for him the difference in the proportion of deaths in the two cases —

Mortality in Materially Hospitals from all Causes in various

	BEFORE THE I	NTRODUCTION OF	ANTISEPT	ics.

Number of lives saved out of the 102,961 since the introduction of antiscotics-

Dr Priestley said it would be seen that while, according to M Le Fort, the maternal deaths in European lying in hospitals were 34 21 per 1000 under the old regime, the mortality is now reduced to somewhat less than 5 per 1000. This computation, put in another way, indicates that if the former rate of mor tality had been maintained 3522 maternal deaths might have been expected; the actual deaths were only 511 In other words, 3011 lives of mothers were saved as the result of new and words, 3011 lives of monters were saved as the result of new and purely scientific methods of treatment. This, he thought, might fairly be stated to be one of the most striking trainiphs of preventive medicine. If was no mean achievement to rescue from death more than 3000 lives of women in the acme of their multirity, and when their lives were most valuable to their families

Inspector General Lawson and Mr. Weaver spoke on this

Dr Lewis Sambon, delegate of the Municipality of Naples Dr. Lewis Sambon, delegate of the Municipanity or sapies, read a paper on "Measures adopted for the Prevention of Infectious Diseases and their Relation to our Knowledge of Epidemics." He first pointed out the similarity, which is most striking, between the mode of development and diffusion of infectious diseases and some insect petits, such as locusti for infectious diseases and some insect petits, such as locusts for instance. Both have likewise their endemts areas, both their seasons of development, both in some years spread more widely, and at long intervals give rise to regular plague; both migrate in the same constant direction, and both die away out of their endemic areas, substiding in the sirrugel for like. He said that the diffusion of species by currents and winds will make us understand the peculiarities in the spread of infectious diseases, which had given rise, in all time, to the most strange theories. The influence of almosphere has been very little studied in conthe registration of the prevailing lower winds during an epidemic, but serious bacteriological researches in the sinking sediment of the atmosphere and in meteoric waters of animals being carried by regular winds or wind-storms far beyond the limits of their homes are universally known Invests of all kinds are often caught hundreds of miles from the In-sects of all kinds are often caught hundreds of miles from the nearest land, out on the high seas. North American birds not unfrequently are carried across the Atlanic to Seotland Far more important is the influence of winds and currents in the distribution of microseopic animals. These minute organisms or their germs, generally adhering to other larger elements of dust, are ruised and carried by the wind until they are allowed to sink again to the soul when the air is in stillness. About quarantine Dr Saml on said that not only our modern investigations proved them useless, but that a long experience has utterly condemned them. England has been accused of has utterly condemned them. England has been accused of being commercially and politically interested in the abolition of quarantine, and this preconception has unfortunately prevented have promoted their opposition to quarantine. No nation can loost of having held public health so high shove commercial interest, and we must also remember that the English, at one Ouarantine was first instituted by the old republic of Venice, Quarantine was first institution by the one republic of Ventice, whose life and power lay entirely in commence; and Dr. hambon said that, although it had proved so disastrous to finance, so useles to anniation, and so ventious to libetty, he was proud that they were a glory of his country. Dr. Sambon concluded that the most important and pechagin the only statisfactory means against infectious diseases was the entirely of the property of the contraction. sanitation of towns and the hygiene of men In speaking of the sanitation of towns he said how vast areas of the old city of sanisation of forms he said now vast areas of the one one of Naples had been recently pulled down and new districts had been built. A large and splendid supply of water has been introduced since 1887, and when the drainage is completed, Naples will be one of the healthiest towns of Furope He spoke of the will be one of the healthiest towns of Furipe. He spoke of the poor classes of all our large towns, and said how they were the culture grounds of epidemics, and finished by saying that it is not enough to improve the sanitary conditions of a town, but that the principles of hygiene should be impressed on the minds

that the principles of hygene should be impressed on the minds and consciences of people, because there could be no public hygene where private hygene was not understood. Deputy-Surgoo General Bactock, C B, and Sir Vincent Barnington, delegates of the Metropolitan Asylums Board, read a joint paper on "The Hospital and Ambulance Organization of the Metropolitan Asylums Board for the Kemowal and Isolation of Infectious Director." diagrams, and models

Surgeon-General Bostock said that the present accommodation

for fever and diphtheria consists of aix hospitals :-

Name	Postion		Acreage.	No. of be	ds.	Population served.
Eastern .	Homerton	٠.		. 442		1,114,419
South-Eastern			11	. 46a	***	941,381
South Western			8	- 340		582,5QZ
Western .	Fulham		6			690,138
North-Western .	Hampstead		11	435	-	889.314
Northern	Wischmore Hil		36 .	480	***	_

The first five are in London. The Northern is for convaies-cents, and is four miles outside the northern boundary of the

district. The position of these hospitals is shown on the man The average length of the journey a patient has to be carried to reach the hospital nearest to his home is three and a half miles. Daring 1886-87 the number of beds in the eastern and western districts was found to be insufficient, and steps are now being taken to establish an additional hospital in the North-East of taken to establish an additional hospital in the North-East of London, and to increase the number of beds in the Western Hospital to 400 These additions will give a total number of beds for fever and diphtheria of 2959, or one bed for every 1423 inhabitants The total number of cases of fever and diph theria admitted into the managers' hospitals from 1870 to the end theria admitted uso the manageri hospitals from 1870 to the end of 1890 was \$5.50a. The accommodation for unall por it the Floating Hospital at Long Reach, fifteen unles below London the state and the Catalata, the Employmen being used for administrative purposes, and 80c in the convalencest liospital at 1150 below. The number of small port as the Catalata, the London the ships, group a total of 1150 below. The number of small port cases admitted and added 1026 cases other than small port, making a total of \$5.007 admissions. The river service is cachisvely used for small port cases, and consists of three whares on the Thanes and London cases, and consists of three whares on the Thanes and London for the emharkation of patients The wharves, as shown on the map, are the "West" at Fulham, the "North" at Poplar, and the "South" at Rotherhithe In each there is a floating pier in deep water, approached by a bridge, and a shed into which the ambulance carriage drives, with an examination room. As an example of the work, it may be stated that during the smallpox epidemic of 1884-85, 11,060 cases were removed from their homes to the Floating 11ospital, 175 doubtful cases were sent from the wharves to the land hospitals, 38 cases were detained in London on account of fog, and 35 persons, not having small nox at all, were vaccinated and taken home. The greates pox at all, were vaccinated and taken home. The greatest number of patients taken down to the Floating Hospital in one day was 104, by the Red Costs, in three trips A the close of the epidemic the Ambulance Committee were able to report the epidemic the Ambulanic Committee were able to roport the statisfaction they felt that so large a number of persons of many helplers from disease, had been carried in all weuthers, throughout all seasons of the year, and to a great extent during the hours of darkness, without disconfior or detriment to the pattents, and without mishap to any person ment to the pattents, and without mishap to any person. whatever.

Sir Vincent Barrington, after urging the importance of a sanitary point of view, presented statistical papers of fever and small-pox cases treated in Board hospitals. He commented upon the supposed prevalence of discase in 1887, and urged every publicity to be given to Board work, to get and urged every publicity to be given to board work, to get over the old prejudices of the working classes against send-ing patients to the isolated hospitals. He showed a chart demonstrating that the increased use by the public of the Board hospitals and the transport from 1879 to 1890, had been followed by steadily decreasing fever mortality in London Now over half the cases of scarlet fever in all London are probably treated in Board hospitals. He referred to the improved sanitation of dwellings and the decreasing severity of the type of the disease as factors in the decreased mortality observed duesase as factors in the decreased mortality observed. He presented small pox pedigrees in non epidema times, showing in one case that 19 persons, in another to persons, were indeted from a single case. Also that 20 cases of the 32 treed in the property of the presented the forms for recording the endence of the extense of vaccious of the presented the forms for recording the endence of the extense of vaccious of the improved systems. adopted after conferences with Board medical officers and the adopted after conferences with Board medical officers and the Local Government Board, and advocated other sanitary bodies adopting the same system, thus facilitating the compilation of statistics, invaluable for the advance of science, and therefore for the treatment and check of small-pox, and the consideration

for the treatment and check of small-pox, and the consideration of protection by vaccination of protection by vaccination.

The product of the protection of

Prof Stokvis and Dr. Dickson spoke on the subject.
Dr Pistor, of Berlin, read a paper entitled "Ueber die Desinfection," of which the following is an abstract. Dr Pistor
dealt with the general rules and methods to be observed in the
dunifection of infectious diseases. Such rules should be short,
cleai, and capable of being understood by everyone Incineration and boiling for half an hour are, of course, very effectual disinfectants, but they are not always applicable A I to 2 per cent solution of caustie soda is a very useful disinfectant. Other cent solution of caustie soda is a very useful disunfectant. Other methods are steaming, mechanical cleaning (such as rubbing, brushing, &c.), carbolic acid solution (2 to 5 per cent.), limewester containing about 20 per cent of caustic lime, and a 1 to 2 per cent solution of calcimed carbonate of soda. These methods and solutions are effective against all the poisons of infectious diseases. The head of the house or institution ought to be responsible for the disinfection under the direction of the doctor. and a record ought to be preserved of the mode of disinfection used

PHYSICAL UNITS AND CONSTANTS

Illustrations of the C.G.S System of Units, with Tables of Physical Constants By Prof Everett, F.R.S (London: Macmillan and Co, 1891)

THIS may be taken to be the fourth edition of a work first published by the Physical Society in a somewhat different form Those who know Dr Everett need not be told that he has done everything that it is possible for an accurate, paintaking author to do, to bring each successive edition as near to perfection as possible. The value of the work to the physics investigator is exceedingly great, as everybody knows, but it is not so generally well known that it is an excellent class exercise book for students. There is much new matter in this edition, institution, and it is an excellent class exercise book for the physical properties of its possible chemens, magnetic properties of its propert

The labours of many men have given to the present generation this beautiful system of units, which has made physical calculation so easy, and which has pointed out in certain cases the directions in which new discoveries might be expected. And it only requires a short study of certain parts of this book to put any student in such possession of the system that he can use it with certainty and ease. Indeed, to become well acquainted with the scientific method of calculation has almost been made too easy for certain clever men of our acquaintance. It is far nobler to swim the Hellespont than to cross in a steamer At the present time many clever men are possessed by a mania for crossing the Atlantic in boats of eighteen feet keel It adds much more to one's credit to talk of all kinds of hybrid and home-made magnetic influences, than to use the simple idea of self-induction. In the same way it is unfair to say that certain practical engineers shirk the study of Dr Everett's book, it is much better to put it that these gentlemen have too much criginality to follow the easy path, and when in their practical applications of physical principles they adopt all sorts of ingenious units of their own manufacture to whose use there are limits in all sorts of ways, we can even feel sorrowful over their skilfulness, without attemptto thwart their ambition.

The mechanical engineer is accustomed to the use of a curious unscientific want of system in his calculations. His unit of force is the weight of a pound in London His velocity is in feet per second, perhaps, in the very same calculation as that in which his pressure is in pounds per square inch. It seems to be too late to change this No engineer can venture to educate his pupils in the use of the C.G.S system for mechanical engineering calculations Mrs. Ali Baba measured her gold by the quart, and a mechanical engineer thinks and designs and talks with other engineers in the usual shop units; and we may as well think of altering our decimal system to a duodecimal one, as to talk of an alteration in the mechanical engineer's methods of calculation. It is a very great pity, but the difficulties in the way of reform seem to be insurmountable. The story of these difficulties is too long for the present

notice. But in new applications of physics, in electrical engineering, for example, the use of the C G S. system is not only easy, it requires a large amount of ingenuity in any engineer to calculate in any other than in C.G.S. units, unless, indeed, he ignores all the experimental determinations already made for him and tabulated in the C G S system And yet such ingenuity has already been exercised, and laborious investigations have been carried out by some electrical engineers, with the result that certain parts of electrical engineering are getting to be even more unscientific in the units employed than any part of mechanical engineering. On behalf of the culprits we may say, however, that even Dr Everett's book their best guide-has not given them the precise information that it might have done. In the subject of heat, we can now ignore the steam-engine constructor. we can say to him, "Go on using your wretched pounds per square inch and your foot-pounds per minute, and we will go on using our dynes per square centimetre and our ergs per second because we are nearly independent of one another", but we can make no such speech to the electrical engineer. We physicists have to say to him that we rely upon him to make new discoveries, to state to us new problems, and if he gives us information in vague units of his own, we cannot tabulate it for general use, and if he does not state to us his problem in the usual language, we are unable to understand him, and we can be of no mutual use to each other But when he says to us that our language is cumbrous, that he has ideas to express for which we have no words, when he uses towards us, properly for once, that adjective "academic" which has been more misused than Shakespeare's word "occupy," the culprit and the judge change places.

We can blame him if he invents unsystematic units, but not until we have given him the language and units that are correct. And in some particulars the electric engineer has the right to blame us. For example, our definition of unit electric current is so stupd that a multiplier or divisor of \u03c4 or 4\u03c4 enters quite unnecessarily into all electro-magnetic calculation

Concerning electro-magnets and the magnetic circuit of a dynamo machine or a transformer, the practical engineer has a simple and quite modern way of considering problems, not yet recognized in such orthodox books as this of Dr. Everett Magneto-motive force and the magnetic resistance of a circuit are expressions which cannot be found in such a book, and it is not at all unusual for the orthodox physicist to treat the idea underlying the use of such expressions with profound contempt. The engineer and experimenter care less than nothing for "magnetic susceptibility" or for "intensity of magnetization," or for "free magnetism", these are, to him, mementos of the time of twelve years ago, when the inventor made bricks in Egypt, and the very cleverest mathematical electricians were only distinguished from other inventors by the greater magnitude of their blunders Dr Hopkinson and Mr Kapp and Mr. Bosanquet have given us simple ways of dealing with practical problems, and some of these are now known to every apprentice of an electric engineering factory, but we know of no mathematical treatise in which they are recognized. Is it too much to hope that Dr. Everett, in his next edition, will ignore the orthodox critics, and

mention ambere-hours, and ambere-turns, and Board of Trade units? It would perhaps be going too far to expect him to speak of the drop of potential per ampere in 100 yards of "a cable of nine-seventeens," for he does not aim at displacing the electricians' pocket-books; but it is to be remembered that of all engineers the electrical engineer is the one who is most inclined to orthodoxy. who most leans upon the mathematician and physicist. who is most likely to use such a book as this, and if Dr Everett can stretch a point in his favour, and devote, say, four pages to "electrical engineers' pocket-book" information, it will bind the electrical engineer to orthodoxy for ever Why, for example, should Dr Everett define the "impedance" of a circuit merely with reference to the circuit when conveying one particular kind of alternating current?

This book deserves much more than a short notice, and the time may perhaps come when one of our leaders will write a long critical article on the whole subject of units, pointing out the great differences in derivation of calorimetric units, for example, and the mere dynamical units employed in mechanics and electricity-an article which will teach the student that, although electric resistance has the same dimensions as a velocity, yet this is a very different thing from the statement that it is a velocity; that, in spite of Paris Congresses and Committees of the British Association, see ohm is a scientific name. and quadrant is not But, over and above all this, the writer of the article must not be, as the present reviewer is, a poor specialist, he must criticize this book from the point of view of the general physicist. This book contains the results of all the best experimental work of more than a century It is a book of mnemonics. A single line in the whole book recalls to us those magnificent memoirs of Dr Andrews which revolutionized our ideas on liquids and gases, and yet that single line is quite enough to the physicist It is dreadful and yet pleasing to think that all the work of a great man, or perhaps of a generation of great men, may be condensed into a single line of information in such a book as this Would Dr Andrews trouble himself very much over this fact if he were alive? or would he console himself with the thought that every physical fact discovered since 1869, and here recorded, was, to some extent, discovered through him, because he had made all physical workers his pupils? Would he need the consolation that Newton is not once mentioned, and that Sir William Thomson has less space devoted to him than the meanest of his pupils? Hundreds of years hence, the scientific world will be the better for the experimental work now going on, and it will have forgotten the name of almost every worker Our determination of something is only right to four significant figures, and so it will never be quoted because a man of next century will have measured it with accuracy to five significant figures. How many of us can be sure that a single line of such a book as this, published a century hence, will be devoted to the record of any of his experimental results? Is there or is there not a satisfaction in knowing that, one thousand years hence, the names of even Faraday and Maxwell and Thomson will be as little known as ours. The age deserves a Homer, and a memory of thousands of years; and one book of the epic ought to be

thousands of years; and one book of the epic ought to be a list of all the men mentioned by Dr Everett, saying NO. 1143, VOL. 44] what weapons each of them had brought for the common fight against the powers of darkness. Bút alas, the new Homer will probably not come into being for another three hundred years, and he will be a blind poet, and he will probably immortalize the wrong people.

JOHN PERRY.

OYSTERS

Oyslass and all about them Being a Complete History of the Titular Subject, exhaustive on all points of necessary and curious information from the Earliest Writers to those of the Present Time, with numerous Additions, Facts, and Notes. By John R. Philipots (London and Leicester Richardson and Co., 1891)

The Oyster a Popular Summary of a Scientific Study By Piof W K Brooks, of the Johns Hopkins University (Baltimore Johns Hopkins Press London Agents Messrs Wesley, 1891)

H ISTORIANS of the oyster revel in ambitious titles

"The Oyster Where, How, and When to Find,
Breed, Cook, and Eat it" suggested a somewhat extensive
field for the tiny octavo which Cluikshank illustrated,
but yet greater anticipations are raised by the title of Mr
Philipot's contribution to the subject.

Unfortunately, this promise is not borne out, not from lack of labour on the writer's part, but from the want of that critical knowledge which can alone make a compilation of this nature valuable Mr. Philpots has thrown together, with but little arrangement, into two volumes of 1300 pages, scraps from every conceivable source relating to the oyster, and this without any critical treatment whatever all are ovsters that come to his dredge Since at least as much erroneous information is current about the oyster as about any other well-known animal, and since it appears to exert nearly the same deleterious influence as the horse on the truthfulness of those who deal in it, it will be readily understood that the 1300 pages abound with errors and contradictory state ments, and form a most untrustworthy guide to the complicated subject of which they treat

The melancholy side of the situation is that, had the compiler, evidently an enthusiant for his subject, devoted the time and labour expended on the collection of paragraphs from untristworthy authorities, to qualifying himself for his task by obtaining a personal and practical acquaimtance with the oyster in all its relations of life, he might have produced a less bulky work, but one of permanent value, as it is, the only passages which we have been able to identify as indicating that Mr. Philipots has seen an oyster or an oyster-bed, are to be found in his account of ten sorts of oysters sent to him by a London dealer, among which, by the way, the real native does not occur (pp 33-36), and in chapter ux, containing a short account of the Poof Sharers.

To correct the errors of Mr Philpots's authorities, and to indicate his omissions, would be to criticute, not one book, but all the readily accessible matter which has been written on oysters for the last half-century; accessible matter only, for even as a compiler Mr, Philpots has not the requisite qualifications for his task, being seemingly dependent for his information about foreign oysters upon the translations and abstracts which have

appeared from time to time in the Report and Bulletin of the United States Fish Commission, and upon the Hand-books, &c., to the International Fisheries Exhibition. These, with Grenville Murray's "The Oyster, Where. How. When," &c. (1861 and 1863), Williams's "Silvershell; or the Adventures of an Oyster" (1856). and Evton's "History of the Oyster" (1858), are the chief part of his stock-in-trade, to which may be added newspaper articles, reviews, extracts from popular natural histories. &c Besides these "authorities," some fifty pages, largely taken from Gwyn Jeffreys's "Conchology." deal with Brachiopoda (1), Anomiadæ, Pectinidæ, and Ostreidæ; under the latter family there is an account of Ostrea edulis, but none of Ostrea (Gryphaea) angulata and virginica, although the book does not profess to be confined to the former species, and about 212 pages are occupied by reprints of Parliamentary papers of various

The only chapter in which we are at one with Mr Philpots is that in which an appeal is made to the Government to take the "oyster question" seriously in hand, though even here we cannot but regret the tone in which he speaks of the Board of Trade Unhappily, however, there is no denving the fact that the inspectors sent by the Board to report on oyster fisheries have often been unfit for their task, and have, sometimes at any rate, been freely fooled by interested parties, for want of a little practical acquaintance with their subject. This has been pointed out again and again, not only as regards oyster fisheries, but also iii connection with other fishery questions; but it cannot be pointed out too often A point to which Mr Philpots should have drawn public attention is that, if the proposition to move the London diamage outfall to Foulness take effect, the best of the few remaining grounds for breeding the almost extinct "native" (sensu stricto) will in all probability be ruined

A book of a different calibre is that of Prof Brooks It is avowedly merely an attempt to rouse the State of Maryland to take such measures with regard to the oysterfisheries as can alone prevent their ruin, measures such as some other States have already taken with marked success. It is hardly necessary to say of Prof Brooks that his little book is a clear and accurate summary of what is known about the American species, for few men can speak with more authority on the subject. We can only hope that the Legislature to which he appeals may be more far-sighted than our own. Had the restrictions which he advocates been laid on our English public beds fifty years ago, the rare "native" might be almost as cheap now as in those almost forgotten days when the market was not yet flooded with French and Dutch produce posing as the genuine article, and oyster grottos were a familiar feature of the streets

THE DESTRUCTION OF MOSOUITOES. Dragon-flies v Mosquitoes (New York D. Appleton

and Company, 1890) THE book before us consists of three prize essays written in response to a circular issued in 1880 to "The Working Entomologists of the Country," offering certain prizes for essays containing original investigations

NO. 1143, VOL. 44]

The prizes were offered by Mr. R H. Lamborn, whose position as Director of the Lake Superior and Mississippi Railway had caused him to spend a considerable time encamped in the swampy forests which surround the head of the great lake Here he came into contact with mosquitoes of the most irritating kind, and here he made the interesting observations on the "destruction by dragonflies which stimulated him to offer the above-mentioned prizes. The lines laid down in the circular as to the direction which the investigations should follow have reference chiefly to the destruction of these insect pests by dragon-fites. The competitors were also required to examine which species of Odonata are best adapted for the purpose, to investigate their habits, and the possible methods of breeding them in large numbers. But although this line of inquiry is suggested, the practical object of the investigation is to determine whether it is possible to diminish or extinguish the novious Diptera, and if so, by what means

The essay which gained the first prize is by Mrs C. B Aaron, who gives a careful account of the habits and life-history of both the Diptera in question, and of the Odonata, and then considers the advisability and the means of exterminating the former. The gravest charge which is adduced against these Diptera, apart from the irritation they cause, is that they act as carriers of such parisites as Filaria, and possibly of some species of I enia, whilst they undoubtedly serve to disseminate Bacteria associated with certain infectious diseases. In their favour it may, however, be said that they act as very efficient scavengers, especially during the larval period of their life-history, and it is a very open question whether the world would be much benefited by the total extinction of the two genera Culey and Musca Without attempting to decide this point, Mrs. Aaron proceeds to consider the possibility and the cost of attempting their extermination

The plan of pitting the dragon-fly against the gnat-a plan similar to that which Prof Riley has brought to such a successful termination by encouraging the destruction of the orange scale, Icerya purchasi, by means of a small beetle, the Vedalia cardinalis, imported from Australia-is dismissed in a few words, for reasons which are considered at greater length in the following essays; but several mechanical means are suggested, the most promising and cheapest of which, in the case of the mosquito, is to spray with crude petroleum all collections of stagnant water which cannot be easily drained. The oil forms a thin film on the surface of the water, and effectually clogs the aperture of the breathing tubes as soon as the larve come to the surface, as they must do, for air

The authors of the two remaining essays, Mr. Weeks and Mr. Beutenmuller, divide the second and third prizes The former commences his essay with a valuable table, giving details of the time of appearance, of the comparative voracity, and of the habitat of sixteen species of dragon-fly found in the neighbourhood of New York. From these, three are selected-Anax junius, and Eschna construta and heros - as the most likely to prove destroyers of mosquitoes When, however, the life-histories of the opposed insects are compared, it becomes at once on methods for destroying the mosquito and the house-fly, evident that we must not trust to the Odonata to rid us of

the biting Culicidae The breeding and artificial rearing of dragon-flies present almost mauperable difficulties, for, when the larval stage is attained, each individual would have to be isolated, because they are apt to devour each other when confined in a limited space. Irrespective of the question of breeding, an insect which produces but one brood a year, and lives but a few days in the image condition, has little chance of seriously affecting a race whose numerous annual generations succumb only to the severest weather. In its natural condition the dragon-fly does not correspond sufficiently closely with the mosquito, either in time or space, to give it any real chance of effecting the destruction of the latter, its breeding-places are also more restricted, as it requires a volume of water which is constant for some little time, whereas the mosquito, with its quicker metamorphosis, can make use of any temporary puddle

The conclusion to be drawn from all three essays is, that if a serious attempt is to be made to combat these most annoying insects, the means to be adopted with most chance of success he rather in the direction of draining wamps, raising fish, and encouraging waterfowl in the infessed ponds, and, where it would not be injurious, using crude oil, than in any efforts to increase the supply of dragon-files.

Mrs. Aaron and Mr Beutenmuller have appended to their essays useful last of papers on the subject of their work; and the latter has added a preliminary list of the Odonata in the State of New York, and a very useful catalogue of the "described transformations of the Odonata of the world." The book is illustrated with several plates, which deput stages in the life-history of the insects in question, and various mechanical devices for attracting mosquitoes, by means of lamps, to an oily grave, and for spraying with petroleum the water in which they breed

Materials for a Flora of the Malayan Pennsula No 3 By George King, M.D., F.R.S., &c Repnnted from the Journal of the Asiatic Society of Bengal, Vol. LX Part 2

Dis, Kino's third contribution towards a flora of the Malayan Peninsula contains the Malayande and comprises almost as large a proportion of new species as the two Malayande Peninsula contains the Malayande, and comprises almost as large a proportion of new species as the two manner trends, but the proposed of the pr

Zoological Wall Pictures. Three Diagrams, each 32 inches by 42 inches. (London: S.P.C.K.)

The Animals of the World, arranged according to their Geographical Distribution. Third Edition, Revised and Re-drawn. Size, 58 inches square. (London. Moffatt and Paige)

THE first named depart (1) fishes, as represented by the cod, eel, and herring; (2) chelonians, as exemplified by the common water tortoise and the Greek land tortoise, together with drawings of parts of the chelonian skeleton; (3) insect peats, in the persona of the Pine Bark and Colorado beelles, the larve of which are delineated The diagrams are both bold and accurate, and good of their class.

The second named embodies an attempt to represent the distribution of the animals selected in latitudinal series. The plan, although a good one, is manifestly insufficient, insamich as by its means no provision can the picture may be recommended. Its meaning is at once obvious, and a fact such as the occurrence of seals and whales at extreme latitudes, which at once arrests the attention, is sufficient in 1stell to arouse the spirit of "bound" of the article ""bound" might with advantage be substituted for the article ""The "which beads the tille

Croset's Voyage to Tasmania, New Zealand, the Ladrone Islands, and the Philippines, in the Years 1771-72 Translated by H Ling Roth Illustrated (London Truslove and Shirley, 1891)

IN 1769 a Fahitian was brought to Europe by Bougainville as "a human curiosity" Afterwards he was sent to the Mauritius, the Governor of which was instructed to forward him to his destination The task of restoring him to his native land was undertaken by Marion du Fresne, who was then a well-to-do resident in the Ile de France, and thus originated the expedition the story of which is recorded in the present volume. The party staited in two vessels, and Marion proposed, in the course of the voyage, to do much exploiing work—a kind of enterprise for which he seems to have been well fitted, as he had been a distinguished officer of the French navy Unhappily, some members of the expedition, including Marion himself, were massacred by the Maories The voyage, however, was continued, and in 1783 an account of it was published which had been compiled and edited by the Abbé Rochon, the well-known traveller, from the log of M Crozet, who, after Marion's death, commanded one of his two ships It is this account which Mr Ling Roth has translated The work will be read with interest by students of the history of geographical discovery, and a good many of M. Crozet's statements about savage life have considerable value from the point of view of the ethnographer and the anthropologist A preface, and a brief reference to the literature of New Zealand, are contributed by Mr J. R Boosé, Librarian of the Colonial Institute, and the volume contains, besides maps, very good illustrations of some works of Maori art

Levingstone and the Exploration of Central Africa. By H. H. Johnston, C.B., F.R.G.S., &c. (London: G. Philip and Son, 1891)

THIS volume ranks with the best of the series to which it belongs.—"The World's Great Laphorers and Explorations." Mr Johnston realizes fully the splendour of Livingstone's achievements, and has succeeded admirably in bringing out their significance in the history of African exploration. He begins with two excellent general chapters dealing with the "natural history" and the "human history" of Central Africa, and afterwards be gives vivid accounts of all the various regions traversed by his hero. Thus the reader is enabled to form his own opinion as to the value

of Lumgatone's services. The strictly bographical part of the work is equally well done. All the world agrees that Livingstone was one of the noblest men who have ever devoted themselves to travel. This is felt strongly by Mr. Johnston, and he has been able to express his feeling effectively without extravagence and without any attempt effectively without extravagence and without any attempt readers, but may be studied with pleasure and profit by readers, but may be studied with pleasure and profit for readers, but may be. There are many good illustrations from photographs or drawings by the author, and seven maps by Mr E. G. Ravenstein

Downing Lodge, September 17.

Notoryctes typhiops

ALLOW me to protest against the misnomer "Mansqual Mole" applied to Dr. Strilling's marrelloss mammal by Mr. Scalete, both in the Timer and in NATURE "Mole-like Marsupath" is may be but the other phrase his quote a different control of the contro

"W = Mg"

I wish that Prof Greenhill would kindly explain to a bewildered reader of your paper the nature of his quarrel with "W = Mg_* " and with the writers of "theoretical" treatises who use this equation

To those trained to regard quantity of matter as measured by its inertia, and who regard the "mass" of a body as the quantity of matter, so measured, which it contains, the equation

tity of matter, so measured, which it contains, the equation $M = M_0$ has a perity dear measure of the certain body. That is mast M_1 , this being the measure of the certain body. The mast M_2 mast M_1 matter of the contract of the containing M_2 matter of the contract to have an acceleration g. We argue, from Restoris experimental laws, that there is a force acting dh it, and we measure that force by a number which is the product of the two numbers, M (the measure of the auss of the body), and g (the measure of the acceleration observed).

NO. 1143, VOL. 44]

If we observe a right suring attached to the body in question and we observe a right suring attached to the body in question for the observed acceleration, we say that M_C measures the tension of of the string, or write "T = M_C." If the acceleration be due to the presence of the earth only, we say that the earth due to the presence of the earth only, we say that the earth managed by M_C. Thus force we call the "weight of the body", and the equation W = M_C gives us the measured by M_C. Thus force we call the "weight of the body" as deduced from the observation of rate of change of momentum

If I felt sure that Prof Greenhill considers M to be still merely a convenient abbreviation for W, I would say more on this matter, but I am in doubt as to what are the views of which he is so strong an opponent I see that the wishes to abolyth "e" from works on hydro-

I see that he washes to abolsh "c" from works on hydrostates. Why? I do not see how we can convenently indicate the dependence [caters, farthar] of hydrostatic pressure on the strength of the earth's gravitational field of force at any given place otherwise than by the introduction of g. But, as I have already implied, I am as yet in the dark as to the pieces, nature of the quarrel between Prof. Greenfull and the theorists Devonort. August 17. W. LARDEN.

[Ws look to America for clear, unprejudiced ideas on the definitions of elementary dynamics, and Mr. Frederick State's letter from California is a valuable contribution, to which I hope Mr. Larden has directed his attention

The quoistions from certain elementary treatises which form Mr. Larden's letter are the statements it was my chief object to dispute, according to this school of writers, the Standard Pounder Weight is not the lump of platnum preserved at the Exchence, but rather it is the pressure on the bottom of the box in which its kept.

If N. Appl.

Let Mr Larden consult the recent Report of the Committee on Electrical Standards, to see how carefully the units must be defined to satisfy practical commercial requirements —A G G]

Willin I was young, I never had the presumption to understand the use of "v" in questions connecting mass and weight, and I fear my boy takes after me II. told me the other day that he understood how a falling

He told me the other day that he understood how a falling body could have its velocity increased per second with n velocity of g, or 32 feet per second, and that he knew that m = stuff in a body, and u v = its weight, but he could not see what the "blooming g" (I think that is what he called it) had to do with the matter.

I replied that no doubt, if we could only understand it, it had a beneficent use in the economy of nature TOMMY ATKINS, Senior

Sleep Movements in Plants.

I stan the other day in a local paper that "Mr. Scennin, the naturalist of Kellert's Arctic Expedition," states that plaint undisposlesp movements it regular intervals (presumably once in 24 hones) dismign the long period when the san never sets a plant does not undergo periodic variations of the kind if it has been been subjected to the regular succession of thyl and darkness. Other instances are the daily periodicity of the strength reads of the strength o

An Oviparous Species of Perspatus

Ms. Destroys observation of the extrusion of incompletely developed eggs in Perspetts is not, as he appears to think, entirely new Capitan Histon was the first to observe it, in Properties in most positive from the support of the same species in my monograph of the geins. No one knows whether species in my monograph of the geins. No one knows whether the properties of the same properties of the same species in my more properties of the same should be a supported to think that the properties of the same should be a supported to think that the properties of the same should be a supported to the same should be a s inclined to think that the process, which has only been observed in animals in captivity, is an abnormal one, and is caused by the alteration in the conditions of the animal's life. We know that the New Zealand species does bring forth fully developed

I hope that Mr Dendy will carry out his intention of fully investigating the development of the Australian species

Trinity College, Cambridge, September 18

A Rare Phenomenon

On a visit to Dunecht, I was just leaving the Observatory about 11 18 C M T on the 10th inst, when I saw a sharply-defined straight streaks of light arching the sky from east to west It was about 1' in width, and of uniform brightness from side to aide, but more intense towards the westen horizon, where it disappeared behind the trees at an altitude of some 4 Eastward it extended across the constellation of Andromeda near the girdle, quite beyond the convergence point of auroral rays, or fully 120° from the western horizoo This much I saw,

but cannot say if the streak passed north or south of the Great

Nebula. Endeavouring to lay down its course, I perceived that it was rapidly fading, and at the same time drifting southwards at a rate of, perhaps, 1° in five minutes. At 11h 21 om G.M.T. + 23' (1840 o) In the meanime the castern portion not inotes away. Although there was a bright auror: an the north-north-west, I did not think that the streak was auroral in character, but rather that it had been caused by the passage of a large meteonie. Next day, however, I stumbled on an account of a annular appearance seen, together with an aurora, by the Rev Edmund Barrel, at Sutton at-Hone, in Kent, on March 30, 1717 (O S) In the Philosophical Transactions, vol. xx, , after

1717 (O S) In the Philosophical Transactions, vol. xx., after determing an ordinary autors, the account mas,—
By Berr Eleven a Clock, there was (besides the Northern By Byth Eleven a Clock), there was (besides the Northern By Byth Eleven a Clock), the proposed that and a County and County and County and County and County and covering Arturns, proceeded and, pear Herseld and so went over Cor Lowers, and thence to Counting (Program, and so went over Cor Lowers, and thence to Counting (Program, for Siruss had already set) and ceded a butle beyond that Start I shone every bright at first, but faced away in about Eight or Nine Minusles. If it had Noturn (which I am not sure of) it was Southward 1 as aurel for the next Fit of Prightness of the Autora, and in about Seven Minutes, the Eastern Part of the Streak, viz from the Serpent's Head to near Berimies Hair, became visible again the dim, and was quite effaced in Four or Five Minutes more And I did not yet perceive any Change of

ber 14, dated September 12, says - There appeared here last night, between nine and ten, a very bright, luminous arch, reaching from south west to north east. It extended directly over the zenith from horizon to horizon, and formed a very interesting speciacle while it lasted, which was only about half an hour I ts seemed to be of electric origin from its wavy motion, and was slightly tinged pink at the eastern point just above the horizon.

Assuming the correctness of the dates on which the arch was observed—and of the Dunecht date I am quite certain—it seems that this rare phenomenon was visible on two successive mights RALPH Royal Observatory, Edinburgh, September 21. RALPH COPELAND.

NO. 1143, VOL. 44

Last Friday, the 18th, my attention was called at 9 p.m. to a most remarkable appearance in the sky. It consisted of a luminous band stretching from the eastern horizon to the west, and passing a little to the south of the zenth 1 t was first een and passing a little to the south of the routh. It was first seen there at 8 20, and began as a lumnous ray coming up from the west, but when I first saw it, it had extended as described from sets to east. It was like a straight and of a large coment with as head below the hormon, or the treek of the beam from a powerful electric search light. It causatre med lay a little to the passed through Corona Storeals. The night was a brilliant satisfact one, and small stars could be seen through the luminous hand! It was seen in the Co Kidare, 50 miles from here, and here it passed through the zenth also, which would show that it was a largest altitude. It gradually facted away, and was gone at 9 20. It would be of nitnests to know if it was longer at 17 th would be of nitnests to know if it was observed in other parts of the country

Daramona, Streete, Co. Westmeath, September 16.

SOME NOTES ON THE FRANKFORT INTERNATIONAL ELECTRICAL I XHIBITION

ON arriving in Frankfort one finds oneself in a lofty, palatial railway station, compared with which King's Cross looks mean and Victoria Station is a shanty This new terminus at Frankfort is not, as with us, an hotel with trains whistling and shunting in the back premises, it is essentially a railway station, standing And the practical Englishman is as much impressed by the completeness of its internal arrangements as by the anti-Ruskin lesson it teaches, that architectural skill when fit) applied to a railway station can produce as noble an edifice as when bestowed on a temple

Leaving the railway station all is changed. We are on the outskirts of the town, amid unfinished houses, heaps of bricks, vacant plots strewn with rubbish, and the tion is close at hand, composed at first sight mainly of wooden hoardings, temporary structures, "restaurations," and bier hallen it is the Chalk Farm fair again of our early youth, or Chicago in 1873, a month after the great Presenting at the entrance a letter bearing the magic pass-words "Prufungs Commission der Internationalen Electrotechnischen Ausstellung," we are ushered past the barrier with bows, and find ourselves surrounded on all sides by shows—Siemens and Halske's Miniature Theatre. admission 2½d, Electrical Ballet, admission 12, 2s, and 3s, Diving Pavilion, seats 5d, standing room 2½d., Electrical Race Course, 2½d, Siemens and Halske's Dancing Flames, 2½d, and so on, all over the Exhibition grounds. Have we come all these miles, at an invitation conveyed to us through the English Foreign Office, merely to visit a

collection of what are literally two penny-halfpenny shows.

We try one of then, the Miniature Theatre, passing in by the stage door, through the courtesy of Messrs Stemens' representative, and thus avoiding the crowd of people that flocks in at every one of the many afternoon and evening performances. In view of the audience are 48 handles, which work a large puppet show, but a puppet 40 handies, which work a large pupper show, not a pupper show without puppets, without music, without acting, without even a joke. Turning any one of 36 of these handles towards the left turns on a group of luttle white or red or blue incandescent lamps placed at the sides, at the top, and at the bottom of the little stage, but hidden by the scenery from the audience. Turning any one of by the scales within the autoience. Furning any one these handles to the right also turns on the respective set of lamps, but now their brightness can be gradually diminished by revolving one of the remaining 12 handles, which gradually introduces resistance into the particular cucuit. For example, either the red, or the white, or the

blue lamps behind any side wing, top drop, or set piece, can be separately turned on, or all can be turned on and the brightness of the lamps of any one colour varied independently of the brightness of the remainder

A bell unkles, and the curian rises, showing a pretty set scene of a Swiss village with mountains in the background. It is late in the afternoon. The attendant slowly revolves one of the resistance handles—the daylight wanes, the shadows grow long, the sun sets, and the snowy peaks of the mountains are ruddy with the Alpine glow. The effect is so lifetile and so beautiful that a-pon laceous easo of admiration is forced from the audience.

Then the stage grows gradually dark, lights are seen at the cottage windows, but the night is stormy, for the attendant now works the handles rapully, as does the organist the stops when performing one of last's fugues lightning plays on the hills, now a blinding flash lights up the road, the houses, and the waterfall, but the flashes grow less wird, and one sees, or thinks one sees, the most rise, the audience feet the quiet of the bright moonlight night, then the dawn, and finally the sunshine bathes the scene with light!

Since the opening of the Exhibition many theatrical managers, we were told, had ordered complete sets of this electric apparatus, and no wonder, for on it can be already and the managers of colors.

ints electric apparatis, and no wonder, for on it can be applied a symptomy in the music of colour and flainkets "dateing fames," the soles at this show being also well filled with a two-pench-alignent paying audience First, Koenig's manometric flames were described and shown in action, then Dr. Frochech's method of working them from a distance, the elastic membrane of the little gas-bag being punched in and out, not directly by the an puffs, but by the motion of the ferrotyped iron disc of a telephone, the current through which was varied by speaking to a microphone. Next were shown some extending the state of the state

We presume that the considerable number of people who, having paid for their entrance to the Electrical Exhibition, are willing to form group after group and pay nextra fivepence at the many performances that are given daily of these two shows by Messrs Siemens and Halske, are not wholly ignorant of what they are paying to see Probably, therefore, the continued attraction peoples soully another proof of the fast that science, and a love of science, have permeated to a much lower stratum of the nation in Germany than in England

Numerous must be the Germans not much above the level of the sightness at a village faur who have already instend to the explanation of Dr. Frockich's method for exhibiting these alternate current phenomena, and yet exhibiting these alternate current phenomena, and yet the visitors. For it was only some three months ago, when Prof. Ferry showed his new steam-engine indicator to the Physical Society of London, that the President suggested how he thought it possible that that instrument might be converted into an oscillating telescript on a screen the current curve of an alternate current dynamo. But nobody at the meeting was apparently aware that Dr. Frockich had been employing a telephone with a mirror on its disc for this very object—such as the resistance to the spread of rideas introduced

by difference of language
The apparatus employed by Dr. Froelich is as follows.

—A large telephone iron disc has a small piece of looking-giass stuck on tecentrically, and at the back is a horse-shoe permanent magnet, the soft iron pole-pieces of which are wound with a coll carrying the current pro-

duced by an alternate current dynamo. The iron due is therefore pulled more or less by the magnet, depending on the strength and direction of the current passing round its poles. A beam of light from an electric lamp is refecced from this murror on to a screen, and as the alterphical pole of the strength of the strength of the strength of the strength of the current produced by the machine. At least, this will be the case of the natural period of what along the strength of the current produced by the machine. At least, this will be the case of the natural period of what along of the telephone plate to the current produced the period of what along the the period compared with the period time of the current—a condition we presume Dr. Froelich has attended to

and attended to motion of the spot of light at right and gold to the found rine. It Profetch does not cause the telephone to be moved backwards and forwards with no scillatory motion, by the rotation of the dynamo amature, as suggested at the Physical Society of London, but before the beam of light reaches the screen, he causes it to suffer a second reflection from one of a series of small plane vertual mirrors, arranged around the worm-gearing, the quick rotation of the dynamo causes a somewhat slow rotation of this cylinder, but quick enough to produce an apparently continuous houtonid beam of light along the streen if there he no current flowing—that is, if the mirror on the telephone plate be at rest thence, the combination of the vertual and horizontal motions of the beam produces a curve which shows the five berrolls.

five periods

The effect of adding self-induction or mutual induction or capacity to the circuit is instantly seen by the change on the whape of the current-curve on the screen, and the change of phase is also evident from the shifting of the whole series of waves sideways. The comparison between the current waves in the primary and secondary circuits of a transformer is also very pertityl justistated.

Ihis lecture concluded with an exhibition of an apprixus that has been constructed for Dr Froelich for the examination of compound sounds. On a sharp tuning at a uniform velocity, are eight little alternate current dynamos, and by pressing down a piano key, which closes the circuit of the particular dynamo, a current is sent round the soft iron pole-pieces of the horse-shop permanent magnet at the back of a elephone discount of the particular discou

An Englishman finds it somewhat exasperating, if he desires to see the whole Exhibition, to have to be constantly taking out his purse to make small payments for entiance here and entrance their entiance here and entrance their entiance the state of the freedy for the shows go to the Exhibition authorities, they will be saved from the financial Janus that attended the Edinburgh Exhibition of last year, for that Exhibition had to be finally declared bankrupt, even after all the money guaranteed by the promoters had been called a pilenton of electricity to industry and art the mere basas element, that has been so prominent in feature at some of the Fishitions held at Earl's Court, sprenticully non existent at the Frankfort International Electrical Exhibition. International, however, the Exhibition is but in name,

International, however, the Exhibition is but in name, the comparatively small exhibits of one or two Engish and American firms only serving as a reminder of the magnificent collections of electrical machinery and apparatus England and America could have contributed. As a display, however, of the part Germany is playing in the development of electrical industry, the Frankfort Exhibition is most interesting.

Two separate buildings are devoted respectively to electrical railway signalling and telegraphic and telephonic exhibits. The Government have contributed an interesting collection of historical telegraphic apparatus, from which it may be seen that the signalling ratus, from which it may be seen that the signalling ratus, from which it may be seen that the signalling work of the contribution of the contr

There is one detail, however, in connection with the German Post Office, that force steel on the admiration of the foreigner. If you desure to send money, you hand in the sum at the post-office, with a postcard costing 24d, which you address to your correspondent with details of the sum sent, and receive a receipt in exchange. But you need write no letter, send no postal order nor receipt, or correlation of the control of

The display of telephonic apparatio at the Exhibition is large and complete, but owing to the activity of the commercial traveller of the day in keeping English and an administration of the commercial that is being engineer acquainted with processing that is being phone engineer as new A new telephone exchange witch-board, constituted by Messrs. Mix and Genest, contains, however, a point of novelty, and a switch-board contains, however, a point of novelty, and a switch-board Telephone Exchanges and the Berlin Telephone Exchanges.

The general arrangement of an exchange switch-board is as follows. "The writer from all the subscribers are brought to all the clerks at the exchange, so that it is possible for any clerk to onnect any subscriber with any other. In the clerk the context of the clerk of the cler

Suppose, now, that clerk A recoives a request from subscriber 85 to be put in communication with subscriber 500, the first thing to find out is whether the line of subscriber 500 is free, or whether it has been already connected with some other subscriber by one of the other nected with some other subscriber by one of the other subscriber by the subscriber by the subscriber by the subscriber by the subscriber by one of what is sword as a "steamy subscriber by the subscriber b

The ends of the plugs which the clerk presses into the NO. 1143, VOL. 44 various holes, or "spring jacks" as they are technically called, for the purpose of connecting one subscriber with another, are made electrically in two parts, the tip of the holy being being insulated from the remainder by a piece of plug being insulated from the remainder by a piece of the sacch pur of plugs, in such a way that on inserting the to each pur of plugs, in such a way that on inserting the post of the second of a pair of plugs into a spring jack, an instantaneous current passes, deflecting the needle of a galvanoscope of the second inche being recommended the second plug into spring jack 560, and as the top of this second plug into spring jack 560, and as the top of this second plug enters the spring jack steep will be a ninstantaneous swing of the cloth of the second plug into spring jack 560, and as the top of this second plug enters the spring jack steep will be a ninstantaneous swing of the cloth spring jack 560, and as the top of this second plug enters the spring jack steep will be spring jack s

Long-distance telephony is admirably illustrated by the opera at Munich being heard every evening with marvellous clearness at the Frankfort Exhibition, some 200 miles away

The most striking feature of the Likhbition—indeed, the exhibit that has brought many a foreigner hundreds of miles to Frankfort—is the electrical transmission of ower from Laufen, over a distance of 100 miles. No measurements have yet been made by the jury of the exact amount of power that is received, or of the efficiency of the transmission, but as over 1000 sixteen-candle lamps are daily fed by the current, as well as an electro-motor pumping up water to form a large artificial waterfall; the scrulp power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out or 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual power received must be something like it out of 110 actual pow

The plans had to be rapidly formed, for it was not until May 1 that it was definitely decided to carry out the experiment. The transformers have, on the one hand, been duplicated, from an anxious dread on the part of each firm of contractors that the other would not have finished of the proper size are yet only partly ready, and many are defective from too hurned baking. Permission to carry the wires had to be obtained from the four Covernments of Baden, Hesse, Wurtenburg, and Prussa, and every sep of construction had to be taken under the depressing influence of caviling criticism. But in spite of all these means of three overhead bare copper wires, each only o 158 inch in thickness, supported on poles such as are used for ordnary telegraph lines, it is possible to deliver some 110 horse-power at a distance of nearly 110 miles from the water stream where the power is produced; and further, that this may be done without excessive loss in the control of the control of

The result is of international importance. The methods that have been employed (and which will be fully described) will probably not be copied in detail on a future occasion; there are doubtless faults which the cautious engineer can criticise; but the broad fact still international control of the cautious engineer can criticise; but the broad fact still in conception as it has been successful in its realization, the Allgemene Electricitats Gesellschaft of Berlin, in conjunction with the Oerlikon Works of Zuroch, have made the thoughtful realize that towns like Milan, which we within 36, 40, or 30 miles of vast water-power, may say full that the control of vast water-power, may say if it had been shown that such towns atood on an inexhaustible field of smokelses, dutaless coal.

(To be continued.)

SOME POINTS IN THE PHYSICS OF GOLF

I N my former paper (Nature, Aug. 28, 1899) the main conclusions were based to a great extent upon the results of mere eye observations, otien of a very uncertain and puzzing kind. The data so obtained were unfortunately not those required for a direct investigation, so that my processes were necessarily of a tentative character. During and since the last College session I have been endeavouring to obtain some of the more important data in a direct manner. I am thus in a somewhat more character position than before but, as will soom appear, the control of the control of the soft of the fight of a golf-ball.

One point, however, which is both curious and important, has been clearly made out -hammering has no effect (or, to speak more correctly, only an inconsiderable effect) on the coefficient of restitution of a volf-ball. This conclusion, which may have to be modified if the striking surface be not plane, had for some time appeared to me as almost certainly correct, and I have recently verified it by means of the Impact apparatus with which I have been working for some years I procured from St Andrew, a number of balls of the same material and make, half of them only being hammered, the others plain. The results obtained from a hammered, and from an unhammered, ball did not differ much more from one another than did those of a number of successive impacts on one and the same ball In the Badminton Library volume on Golf, Mr Hutchin-son quotes a statement of mine which appears at first sight diametrically opposed to this experimental result, and thus puts me in the position de mer ce qui est el desployee ce que n'est pas. But he has omitted to men-tion that my statement was expressly based on the alle gation that a hammered ball had been definitely found to acquire greater speed than an unhammered one seemed to me even at the time very doubtful, and I now know that it is incorrect] Thus it is clear that the undoubtedly beneficial effects of hammering must be explained in some totally different way There is another, and even more direct, mode of arriving at the same con-clusion. To this I proceed, but unfortunately the new point of view introduces difficulties in comparison with which all that has littherto been attempted is mere child's In short, it will be seen that the problem of a golf-

by its survey is were excessed in the property of the solution of the speed. The solution I then gave was only approximate, and imitted by the assumption that the cosine of the inclination of the path to the horizon might be treated as unity throughout. The illustrations and extensions given were founded on the same basis as was the solution of the sumpler problem. Shortly after it was more exact determiny the help of Bashforth's tables, a more exact determined that the solution of the sumpler problem. Shortly after it was more exact determined the solution of the sumpler problem. Shortly after it was more exact determined the solution of the solution of the sumpler problem. Shortly after it was more exact determined the solution of the sol

As a contrast, take $\lambda = 1$ I, so that $u_0 = 100$ feetseconds. To obtain the observed range we must take NO. 1143, VOL. 44 $\phi = 23^{\circ} 25$, which is considerably too great. The other numbers then become

The first numbers are in remarkable accordance with the numerical details of really good drives which lo bataned from Mr. Hodge, and, were there no other crucial test to be satisfied, the problem might have been regarded as solved to at least a first approximation. But I felt very carried to a least a first approximation. But I felt very carried as the state of the state of the state of the state of the carried was a solved to at least a first approximation. But I felt very carried was a state of the state

The initial speed in the flist estimate seems to be excessive, as will appear from the experiments to be described below. This, of course, is one mode of explaints of the state of the sta

experiments with the view of care determination further to be the help of a ballistic pendlum, but the results of these cannot be regarded as very satisfactory. My pendlum was a species of stiff but light lattice-girder constructed of thin, broadsh, laths. This hung from hard cold kine-legies set well apair, and supported a mass of the clay was plastered into an early cubical wounder. The clay was plastered into an early cubical wounder men to the control of the floor. The ball was divine min to from a distance of about six feet, and as near is possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as near is a possible to the centre of about six feet, and as the consequences of an ill-directed drive. In fact, several rather unpleasant accidents occurred during the trait, especially in the carrier stages, when during the trait, especially in the carrier stages, when the later work. Although the clay was so siff as to

preserve its form under gravity, the ball (when it struck the face near the centre) always penetrated to a depth of more than one disameter, and spisabed fragments of the clay to a considerable disance. These were usually replaced, and the surface levelled for a fresh experiment, as soon as the ball was dug out. The speed of 900 feet per second, thus measured, may be taken as an inferior limit to the injural speed in a really fine drive.

It thus appears that the resources of mere particle dynamics are quite insufficient for the adequate solution of the problem of long driving; though, of course, they fully meet all questions connected with mere approach shots, and that the rotation of the ball must play at least as essential a part in the grandest feature of the game, as it has long been known to do in those most distressing it has long been known to do in those most distressing the same of the same of

powers
In order that the path of the ball may be (for a short time) approximately straight, still more if it is to be concave upwards, the downward acceleration due to grawity material time. The provided in the concavity of the

I have not hitherto succeeded in my attempts to apply even approximate calculation to this altered set of conditions—but it is easy to see, without calculation, that the longer the path of the ball retains nearly its initial inclination to the borroin (even if, in achieving this, it should have to expend part of its energy of translation along with that of rotation, and thus diminish the rangely the longer will be the time of its flight during the carry.

And, as a practical deduction from these principles, it would appear that to secure the longest possible carry, the ball should be struck so as to take on considerable spin—so that the ideal driver should be in truth a Bulger, but with the impostant variation that its bulge should be of considerable curvature and in a prominent part of the face (above the horri) must of course be less than the radius of the ball. How much less can be found only by trial. And, in addressing the ball, the player must stand directly opposite to it. Such clubs, however, could be profitably used only by really good players—men who can his with with gata for if the club they please, tway anythow, and (with ordinary club) manage occasionally to make a really "tall" drive, will probably smash the proposed form of club on the very first appearance of toping. As to those who propel the ball by "skitting" rather than driving, any change must be an improvement, so that they should welcome the proposed novely. The applied with a rough file, and the new system rises at once out of the old.

There is one other point on which opinion seems to be so unsettled that an allusion may be made to it here—the effects of weather on the carry of a ball. Of course, other circumstances being the same, the only direct effect

is on the coefficient of resistance. If this be taken as proportional (roughly) to the density of the lar, it may vary, in this climate, to somewhere about ten per cent. of its average amount, by increase or by diminution. It has its greatest value, and the drive is accordingly shortest, on a dry cold winter day with an exceptionally high barriers of the control o

HOOKER'S "ICONES PLANTARUM"

THE recent issue of the fourth part of vol xx of the third series, with a total of two thousand plates. the third series, with a total of two thousand plates. This useful, and now indispensable, publication was commenced by the late Sir William Hooker in 1837, and the first volume was dedicated to the late George Bentham, who is described in the dedication as an "ardent promoter, not less by his patronage than by his writings, of botany and horitculture "Sir William Hooker started the "Icones' to illustrate some of the numerous novelties in the collections which were pouring into his herbarium from various parts of the world, especially from the southern hemisphere, at that period. With a few exceptions by Harvey, Gardner, and others, the drawings and descriptions were by Hooker himself, and a volume, containing one hundred plates, appeared annually, or nearly so. The first series closed with the fourth volume in 1841. At this date the founder was already Director of Kew Gardens, and he continued the work to the tenth volume, which terminated the second series Two or three of the later volumes of this series were illustrated by the then rising botanical artist, W. H. Fitch. In the tenth volume we find a dedication of the whole ten volumes to George Bentham, in much the same words as the first. This was in 1854. After an interval of thirteen years, the third series was commenced, under the editorship of Dr. J. D. (now Sir Joseph) Hooker, and G Bentham, D Oliver, and J G Baker were contributors Mr Bentham, we believe, financed the undertaking This, the eleventh believe, financed the undertaking This, the eleventh volume, was not completed until 1871, but it is a most interesting volume, illustrated by Fitch, and containing among other things many of the endemic plants of St The second volume of this series, the twelfth of the whole, was also illustrated by litch, and is valuable for the figures of curious new genera founded by Bentham and Hooker when elaborating their "General Plantarum

On the completion of this volume, in 1876, a difficulty arose, consequent on the retirement of the artist, though there was no actual interruption in the appearance of the parts. But it was impossible to replace an artist like Fitch. Indeed, the only alternative was to train a person to do the work. This was not so easily accomplished; there were failures, and so high a standard of excellence has not since been reached. Nevertheless, the present artist gives as good drawings as could be expected from dred, hat specimens, and the botancal details are usually

as full as is necessary, if not all that could be desired.

Since Mr Bentham's death, in 1884, the work has proceeded with greater rapidity, and is now appearing at the rate of a volume per year. It is now published at the expense of the Bentham Triasses, and sold at about half could be the proceeding the process of the country of the process of the

' Of a fund bequenthed by Bentham for the advancement of totanical science.

contain a large number of Chinese novelties. One part of the last volume is devoted to the Stapelia of South Africa. The seventeenth volume is wholly devoted to new ferns, and the first volume of what it is intended to call the fourth series will consist entirely of orchids Three parts of this have already appeared

MY DEAR PROF. TAIT,—In Part IV of your "Foundations of the Kinetic Theory of Gases," 1 "Foundations of the Kinetic Theory of Cases, vou take exception to the manner in which Van der Waals has introduced Laplace's intrinsic pressure K into the equation of virial "I do not profess to be able fully to comprehend the arguments by which Van der Waals attempts to justify the mode in which he obtains the He repeats a good deal of Laplace's capillary work, in which the existence of a large, but unknown, internal molecular pressure is established, entirely from a statical point of view He then gives reasons (which seem, on point of view. He then gives reasons (which seem, on the whole, satisfactory from this point of view) for assum-ing that the magnitude of this force is as the square of the density of the aggregate of particles considered. But his justification of the introduction of the term are into an account already closed, as it were, escapes me. He seems to treat the surface-skin of the group of particles as if it were an additional bounding-surface, eveiting an additional and enormous pressure on the contents 1.ven were this justifiable, nothing could justify the multiplying of this term by (v - B) instead of by v alone. But the whole procedure is erroneous. If one begins with the virial equation, one must keep strictly to the assumptions made in obtaining it, and consequently everything con-nected with molecular force, whether of attraction or of elastic resistance, must be extracted from the term E(Rr)

With the last sentence all will agree, but it seemed to me when I first read Van dei Waals's essay that his treatment of Laplace's pressure was satisfactory, and on reperusal it still appears to me to conform to the requirements above laid down As the point is of importance, it may be well to examine it somewhat closely The question is as to the effect in the virial equation of a mutual attraction between the parts of the fluid, whose range is small compared with the dimensions of bodies, but large in comparison with molecular distances

In comparison with molecular distances
The problem thus presented may be attacked in two
ways. The first, to which I will recur, is that followed
by Van der Waals, but the second is more immediately
connected with that form of the equation which you had in view in the passage above quoted.

In the notation of Van der Waals (equation 8)

 $\frac{1}{2} \mathbf{Z} m \mathbf{V}^2 = \frac{1}{2} \mathbf{Z} f \rho - \frac{1}{2} \mathbf{Z} \mathbf{R} r \cos (\mathbf{R}, r),$

where V denotes the velocity of a particle m, which is situated at a distance r from the origin, and is acted upon by a force R, while (R, r) denotes the angle between the directions of R and r. The intermediate m It represents the effect of such forces, f, as act mutually between two particles at distances from one another equal to ρ In the summation the force between two particles is to be reckoned once only, and the forces accounted for in the second term are, of course, to be excluded in the third term.

In the present application we will suppose all the mutual forces accounted for in the second term, and that the only external forces operative are due to the pressure

Ed. Trans , vol xxxvi , Part 2, p. 261

of the containing vessel No one disputes that the effect of the external pressure is given by

$$= \frac{1}{2} \mathbf{R} \mathbf{r} \cos (\mathbf{R}, \mathbf{r}) = \frac{1}{2} \mathbf{p} \mathbf{r}.$$

so that
$$\Sigma mV^2 = \gamma b \gamma + b \Sigma u \phi(a)$$
.

if with Laplace we represent by $\phi(\rho)$ the force between two particles at distance ρ . The last term is now easily reckoned upon Laplace's principles. For one particle in the interior we have

$$\frac{1}{2}$$
 $4\pi \int_{-\infty}^{\infty} \phi(\rho) \rho^3 d\rho$,

and this, as Laplace showed,1 is equal to 3K. The second summation over the volume gives 3K1, but this must be halved. Otherwise each force would be reckoned twice Hence

$$\frac{1}{2}\Sigma mV^2 = \frac{1}{2}pv + \frac{1}{2}Kv - \frac{1}{2}(p + K),$$

showing that the effect of such forces as Laplace supposed to operate is represented by the addition to \$, the pressure exerted by the walls of the vessel, of the intrinsic In the above process the particles situated pressure K near the surface are legitimately neglected in comparison

With those in the interior

Van der Waals's own process starts from the original form of the virial equation-

where R now refers to the whole force operative upon any particle, and it appears to me equally legitimate am particle, and it appears to me equally legitimate for all particles in the interior of the fluid X vanishes in virtue of the symmetry, so that the reckoning is limited to a surface stratum whose thickness is equal to the range of the forces. Upon this stratum act normally both the pressure of the vessel and the attraction of the interior fluid. The integrated effect of the latter throughout the stratum is equal to the intrinsic pressure, and, on account of the thinness of the stratum, it enters into the equations in precisely the same way as the external pres-sure exerted by the vessel The effect of Laplace's forces is thus represented by adding K to p, in accordance with the assertion of \ an der Waals

I am in hopes that, upon reconsideration, you will be able to admit that this conclusion is correct. Otherwise, I shall wish to hear more fully the nature of your objection, as the matter is of such importance that it ought not longer to remain in doubt
Believe me yours very truly,

RAVINGH L'Abbaye de St Jacut-de-la-Mer, September 7

THE French Association for the Advancement of Science met at Marseilles on September 17, under the presidency of M. P. l' Dehérain, who chose as the subject of his address the part played by chemistry and physiology in agriculture. The meeting comes to an end to-day. There were general excursions on Sunday to Arles, and on Tuesday to Aix, and it is proposed that to morrow, the 25th, there shall be a final excursion to the Mediterranean coast

THE Congress of German Naturalists and Physicians was opened at Halle on Monday by Prof His, of Leipzig. The meeting was attended by 1215 persons, including many dislinguished foreign physicians and men of science and 280

THE Helmholiz celebration, deferred from August 31, is now fixed for November 2. After the ceremony the delegates and others will dipe together at the Hotel Kaiserhof

By the death of August von Pelzeln, which took place on the and inst. at Ober Dobling, near Vienna, Europe has lost one of her foremost ornithologists. He had been in failing health for some years, and had recently retired, after forty years' service. from his post of Custos of the Imperial Museum at Vienna, where he had charge of the collections of Mammalia and birds. Von Pelzeln will be always celebrated in the memory of zoologists by his important essays on the collections in the Vienna Museum, but his most enduring work will be found in the famous "Ornsthologie Brasiliens," wherein he gave a detailed account of the collections made by the great traveller Natterer in the early part of the present century. Only last year he published n the Annalen des & k naturhistorischen Holmuseums, an account of the formation of the collections of Mammalia and birds in the Imperial Cabinet, which is a very valuable historical record The amiability of his character and his great knowledge of zoology had raised up for Von Pelzeln a host of friends in every country, and the news of his death will be received with wide spread regret.

A REUIER telegram from New York announces the death of Prof William Ferrel, the meteorologist.

THE ROYAL Academy of Sciences at Labons send official notice of the decease of their Secretary, José Maria Latino Coelho, who died on the 29th uit. at Cintra, at the age of sixty-six Besides his Secretaryhip of the Academic Royale des Sciences, Prof. Coelho held the post of Director of the Mineralogical Section of the Museum at the Fedile Polivechnique de Labonare.

THE death of M. Wilken, the well-known Dutch ethnologist, has excited much regret in Holland, where his scientific work was greatly appreciated. He was forty-four years of age, and had spent some time as a Government official in the Dutch East Indies, where he had ample opportunities for carrying on his favourite studies.

PROF. K GOESEL has been appointed Professor of Botany in the University, and Director of the Botanic Garden at Munich, in the place of the late Carl v. Nageli

THE Photographic Society of Great Britain announce the holding of an exhibition, which will be open from September 28 to November 12

TRE most interesting part of the Royal Horticultural hocsety?
whibition on Tuesday was a series of the so called camprorous
and insect eating plants. It was hoped that the dapplay of
this series would tend to correct some very musiscen ideas
which are said to be current on the subject. According
to Mr. Weathers, the Austanta Secretary of the Royal Horticultural Society, some persons, relying on what they have
heard, will assert that "these plants can easily dapose of a
beefiteak or mutton chop if their digestive organs are in thorough
repair."

This annual meeting of the Federated Institution of Mining Engineers was held on Tuesday at the Mano College, Brimmeham, and was attended by about 120 members Mr. T. W Embleton, of Leeds, persided In the report it was stated that the Council had not yet undertaken any special inquiry consected with the objects of the Institution, but their attention had been directed to the question of safe explosives for use munes, the mechanical ventilation of mines, and other subjects by the permitten of the Durham Coulcowner? Association and duced in mines by roburite, tottle, and guapoweder had been printed in the Transactions. The North of England Institution had appointed a committee to examine and report upon the pro-offiled "famelees" explosives for use in mines. A paper selecting the geology of the Brimmigham dutriet was read by

NO. 1143, VOL. 44]

Prof Lapworth. A paper was also submitted by Mesers. W. F. Clark and H. W. Hughes, in which the local method of working the third coal was described to the visitors, and the peculiarities of the South Battforkine coal-fields were described in technical detail. Mr. Arthur Sopwith supplied some similar information with reference to the North Satisfordines portion of the coal-field. These two papers were state as a read, and the water of the satisfaction of the coal-field.

A REPORT for the year ending May 3t last, by Mr. G. I. Swanston, the Assistant Secretary of the Marine Department of the Board of Trade, upon the colour tests used in the examination of candidates for masters' and mates' certificates in the British mercantile marine has been issued as a Parliamentary paper The number of persons who presented themselves for examination for masters' and mates' certificates of competency under Form "Examination 2" amounted to 4688, being an increase of 26 over the previous year, when 4662 were examined. In the past year 31 persons were rejected for their inability to distinguish colours, as compared with 23 rejected in the previous year. The number of persons examined in colours only under Form "Examination 26" amounted to 601 Of these, 32 were rejected, being an increase of over 1.8 per cent. as compared with the previous year, when, out of \$39 candidates examined, 29 were rejected. A few of those who failed to pass succeeded afterwards in satisfying the examiners. One man, who, on March 3, described a green card as drab, drab as green, pink glass as salmon and green, standard green as blue, bottle green as red, and neutral as green, passed a fortnight later, having apparently learned to distinguish the colours in the intervening period The mode of conducting the colour-test examination described in the Report for the year 1887 is still in operation, but Mr Swanston notes the fact that the whole subject of colour-vision and the best mode of conducting the examinations are now being investigated by a Committee appointed by the Royal Society.

On his return from Japan, sixteen years ago, Prof Rein, the well-known authority on Japanese art and industry, planted in the Botanical Gardon at Frankfort some specimens of the lacquer-tree (Rhus vernici/era), from which the Japanese obtain the juice employed in the production of their famous lacquer work According to the Times, there are now at Frankfort thirty-four healthy specimens of the lacquer-tree, 30 feet high and 2 feet in girth a yard from the ground; and the young trees, which have sprung from the original tree's seed, are in a flourishing condition. It seems to be proved, therefore, that the lacquer-tree is capable of being cultivated in Europe, and it only remains to be seen whether the juice is affected by the changed conditions The Times says that, to ascertain this, Prof Rein has tapped the Frankfort trees, and has sent some of the juice to Japan, where it will be used by Japanese artists in lacquer work, who will report on its fitness for lacquering. In the meantime, some of the most eminent German chemists are analyzing samples of the juice taken from the trees at Frankfort. and samples of the juice sent from Japan, and should their reports and the reports from Japan be favourable, it is probable that the tree will be largely planted in public parks and other places in Germany In course of time a skilled worker in lacquer would be brought over from Japan to teach a selected number of workmen the art of lacquering wood, and in this way ut is hoped that a new art and craft may be introduced into Enrope. Prof. Rein has been conferring with the authorities at Kew as to the results of his experiment,

THE Hydrographic Department of the Admiralty has just published full details of the determinations of the latitudes and longitudes of six stations on the west coast of Africa—namely, Port Nolloth, Mossumedes, Benguela, St. Paul de Loanda, Sao. Thomé, and Bonny. The observations were made in 1880 by Coamstder T. F. Pullen, R. N., and Mr. W. H. Fuslay, under the direction of Dr. Gill, of the Cape Observatory Whols sationed at Bonny, Commander Pullen succurabed to malarant fever, and Dr. Gill has aunce taken charge of the reductions. The observations would not have been possible but for the courtery of the Officials of the Eastern and South African Telegraph Company, who placed their cables at the disposal of the

Meptunua for July gives a description of the fingate Scilla, set apart by the Italian Government for the hydrographic exploration of the Medicieranean, and of its scientific fittings and instruments. By the end of september the Scilla was expected to be at work along the Italian possession in the Red Sea, investigating the fauna and flora, and the temperature at different doubth.

DR. A ALCOCK, the Surgeon Naturalist of the Marine Survey of India, is able to give a most favourable report of the work done in natural history on board the Investigator during the year ending March 1, 1891 The deep sea researches made great progress. Not only has the work of collection been much more successful since the use of the reversible trawl and wirerope, but the collections themselves are becoming better arranged, so that should it ever be decided to report upon them. group for group, in systematic detail, there will be abundance of material all sorted ready to the hand. Dr Alcock is most anxious that such a report should at some time be undertaken . for apart from the Marine Survey of India nothing whatever, he thinks, is likely to be made known of the life of the depths of the Indian Seas, and of the physical and chemical characters of the deposits now being laid down on the hottom of those seas Further, there are good reasons for supposing that an economic return would follow from the careful investigation of the littleknown semi-bathylisal fauna of Indian waters, and from a comparison between it and the semi-bathybial faunce of the Mediterranean Sea on the one hand and the Japanese Seas on the other

We have received from Messas Philip and Son a new orrey for finding roughly the pointions of the sun, moon, and planess for any hour of the year, and their times of raing, southing, and setting. In general appearance it resembles their well-known planusphere, but, in addition, it is provided with two index aring graduated in degrees of declination—one for the sun, and the other for the moon or planet. The operations are simple, but the instructions given becarely do state to the arrangements but the instructions given becarely do state to the arrangements accompanism to the orient seal to the control of the contro

A BOIANICAL Club for California has been instituted under the presidency of Dr. H. W. Harkness

WE learn from the Botanical Gazette that Prof J M Coulter has been spending the wamer in studying the Cactacess of the borders of the United States and Mexico, under the direction of the Department of Agriculture at Washington; and that are expedition has been organized to investigate the florn of Mount Orisaba, Mexico, under the superintendence of Mr H. E. Seaton.

A QUARTERLY Review of Geological Science in Italy will shortly appear at Rome, edited by Sigg M. Cermenati and A. Tellini.

MR. CHARLER TODU, in his Report on the Rainfall in South Australia and the Northern Territory during 1890, says that without doubt "the feature" of the year was the extraordinary rainfall (especially in the first three months) over the eastern and north-eastern portlons of the continent, which continued throughout the whole year, more or less, in New South Wales, and, whilst giving that colony the wettest year on record, caused some stations to register over 100 inches

LUE Pilot Chart of the North Atlantic Ocean for September states that the most important storm of the month was the hurricane that devastated the island of Martinique on the evening of the 18th, causing the loss of 378 lives The storm seems to have been of comparatively small diameter, and it probably originated south-east of the island, which it passed directly over, on a west north-west track towards San Domingo It recurved over the eastern Bahamas, and thence moved north-east close to Bermuda , where at noon of the 27th the wind blew with hurricane force from north-north west. The weather, the same as in this country, was unsettled and rainy over the North Atlantic generally, especially off the Atlantic coast of the United States, and a considerable amount of fog has been reported. A submarine earthquake was experienced at 10h 30m a m on August 23, in latitude 36' 44' N , longitude 59° 47' W , by the s.s. Robert Harrowing Captain Hughon reports that a strange commotion of the sea increased until the decks were filled with water. At th. p m the sea suddenly fell calm

COLORADO apparently intends to be well represented at the great Cheago Exhibition Besides the inimeral, agricultural, and educational ethibits, the flora and fanns of the biate will be shown in great completeness. Already more than 1000 specimens of plants have been pressed, nearly 200 varieties of fruit have been deplicated in wax, and more than 2000 species of muccis have been monited.

RETURNS have been collected in Prussia, showing the extent to which buildings belonging to the State, or entitled to State subsidy for rebuilding or repair, were damaged by lightning from the year 1877 to 1886 The number of buildings to which the returns relate is 53,502 Of these, 264 were struck during the period in question, or about five for every 1000 buildings in tea years, and in 81 cases a fire resulted The following facts, given originally in the Reichmanzeiger, are reproduced in the current number of the Board of Trade Yournal -Of the 264 buildings struck, to7 had towers, and in six cases only the tower escaped being struck. Of the total number of buildings struck, fifteen were fitted with conductors, and of these latter only one building escaped injury. In two cases the conductor was injured, and on one occasion the lightning passed from the conductor to an iron water pape. In five cases they were so constructed as to be either dangerous or useless, in six cases they were not struck at all, being inadequate for the size of the building, from which it will be seen that conductors are a safeguard against lightning only when carefully constructed and repaired, and hited in numbers according to the size of the building which it is intended to protect The amount of injury wrought by lightning on the 53,502 houses was, on the whole, inconsiderable, being only 1,136,683 marks (£56,831), or 4306 marks (£215) for each casualty, or 21 marks (a guinea) per building in ten years, that is 2 1 marks (about 21) per building per annum

Soas parts of Australia seem to be admirably susted for the growth of the olive Mr. Pennegal Prompson, of Doolies, rays in a recent report that 700 olive trees planted in that district are robust and healthy, and that they produce spleduid oil. He strongly recommends the planting of the olive around vineyard and homesteads for shade and shelter, and to give a pietrareque appearance to the rural home. Apart from the making of oil, the believes it would pay handsomely to grow olive berries to feed pigs alone. Last writer the page at Louise (about 80 cm), they had no other food for upwards of two months, and throve amandagly, their skins having a peculiar shining appear ance, characteristic of samula theory will feel.

TORACCO is being cultivated with much success in the German part of New Guinea, and is said to be better than the tobacco produced in Sumaria. It is expected that there will be a great lacrease in the amount grown during the coming year

ACCORDING to M. d'Amagher, the Russian correspondent of the Monde Economique, a central Agricultural Insuinte is to be established in Russia. It will include several sections—agricultural, geological, meteorological, botanical, chemical, and technological, and branches will be formed in the provinces.

USUSIALLY fine atmospheric effects were produced by the clear weather of the Mediterrasean during the month of July. According to the Mediterrasean Naturealut, the new monthly periodical issued in Malla, the phesonenon of irregalar diffraction was especially shown by the raising of the line of sight to such an extent that objects at great distances, at other times completely concealed from view, were apparently raised so much above their true position as to be clearly discernible from the shores of Malla and Good. The cliffs of the coast line, and the undilatory control of the mountains of Stelly, were to be seen dattactly with the naked eye on July 12 and 12, while the out-lines of Eina view to be sloped against the clear arms sky Although more than 100 miles away, the form of the mountain was perfectly recognizable.

THE honey of the Maila bees has long been noted both for the spenty and for its delicious flavour. A writer in the Mediterranean Naturalist says the flavour is largely due to the extensive crops of sulla, (clove); that are annually ranged throughout the talands, from which the bees derive the largest proportion of their matternal. It is estimated that to collect one pound of honey from clover, 64,000 heads of clover must be deprived on feeting, and 3,75,000 wrists must be made by the bees.

SOME excellent directions for the collection, preparation, and preservation of birds' egg, and nests have been put together by Mr C Bendire, and published by the United States Nationa Museum He begins his counsels by telling the would-be collector that unless he intends to make an especial study of oology, and has a higher aim than the mere desire to take and accumulate as large a number of specimens as possible regardless of their proper identification, he had better leave nests and eggs alone The mere accumulation of specimens, Mr Bendire points out, is the least important object of the true cologist, The principal aim of the collector should be to make careful observations on the habits, call-notes, song, the character of the food, mode and length of incubation, and the actions of the species generally from the beginning of the mating season to the time the young are able to leave the nest

AT one of the meetings of the Wellington Philosophical Society in 1885. Sir Walter Buller, F R S, exhibited a series of the so-called wandering albatross, and expressed his belief that there were two species under the common name of Diomedea exulant, one of them being highly variable in plumage, and the other distinguished by its larger size and by the constancy of its white head and neck But, although that was his conviction, he did not feel justified in setting up the new species and giving it a distinctive name until he could produce incontestable evidence of its existence. From a paper read by him before the same Society in February last, and published in the new volume of the Transactions of the New Zealand Institute, we learn that he had lately had an opportunity of examining sixteen beautiful specimens of both sexes and of all ages, and that as the result of his study of these specimens he had no hesitation in speaking of a new species "It is undoubtedly," he says, "the noblest member of this group, both as to size and beauty, and I have therefore named it Diomedea regra " He exhibited before the Wellington Society a series of both species, and in the course of

NO. 1143, VOL. 44]

some remarks on them stated that they keep quite spart from one another on their breeding-grounds, and do not commingle "except when sailing and soaring over the mighty deep, where a community of interest and a common pursuit bring many members of this great family together."

In the paper in which he deals with the species called by him Diomedes regia. Sir Walter Buller refers to a remarkable characteristic of the wandering albatross-a characteristic which has been carefully studied by Mr Harris At a certain time of the year, between February and June-Mr Harris cannot exactly say when-the old birds leave their young and go to sea. and do not return until October, when they arrive in large numhers. During their absence the young birds never leave the breeding-ground Immediately after the return of the old birds, each pair goes to its old nest, and, after a little fondling of the young one, turns it out, and prepares the nest for the next brood. The deserted young ones are in good condition, and very lively, frequently being seen off their nests exercising their wings; and, when the old birds come back, a young bird will often remain outside the nest and nibble at the head of the old one, until the feathers between the beak and the eye are removed, and the skin made quite sore. The young birds do not go far from land until the following year, when they accompany the old ones to sea When the young are left in the nest at the close of the breeding season, they are so immensely fat that Sir Walter Buller thinks they can subsist for months without food of any kind. Captain Fairchild has de scribed to Sir Walter from personal observation the coming home of the wandering albatross, and the peremptory manner in which the young bird in possession is ordered to quit the nest. so as to make room for its successor

THE habits of the kingfisher (Hakyon vagans) formed the subject of an interesting paper read some time ago by Mr. J W Hall before the Auckland Institute, and now printed in the Institute's Proceedings He raised the question, Is it customary for the kingfisher to capture live birds? Last winter he saw one with a live white eye in its mouth. The tree the kingfisher was perched upon was not many yards distant from him, and he distinctly saw the little wings fintter convulsively as the kingfisher was preparing to beat its prey against the branch. So it could not have been a dead bird casually picked up Perhaps this, he said, was an application of the lex talsons, for, besides being mercilessly persecuted by the small boys with their catapults, the kingfisher was not infrequently captured by the common hawk But sometimes the hawk does not come off best. One day at Parawai (Thames) a hawk sailed round the bend of a hill, followed (accidentally, he supposed) by a kingfisher There at once arose a great outcry, and the hawk came again in sight, bearing the kingfisher in its talons. But, nothing daunted, the kingfisher with its pickage of a bill pegged away at the breast and abdomen of its captor to such good effect that the hawk was glad to liberate its prey, whereupon the kingfisher flew away apparently but little the worse for the encounter, and carrying with it, he need hardly say, the full sympathy of the onlookers. A friend of the author had seen a kingfisher dive under water to escape the pursuit of a hawk.

MK J CRAWFORD, State Geologus and Mineralogust of Noncasqua, visited in 1838 the Amerique Indians, from whose ancesteral name "America" may have been derived, and he has talled submitted to the Botton Society of Natural History some interesting notes about them. They occupy a hilly region is the gold-mining part of the district of La Libertad, Nicasqua, where these are "true fissures," each containing gold in sufficient quantities to give profits to the mine and mill owners now "operating" them. A few welted masses of gold, weighting from half an onnee to two onnees each, plered with

holes, and in form supposed to have been made and used as ornaments before the Spanish occupation, have been discovered in the district; and Mr. Crawford repards it as a fair inference that the Amerrique Indians who dwelt in that part of Nicaragua at the time of its discovery by Columbus, September 1502, picked up and occasionally mined, melted, and used gold for sacred or ornamental purposes The Amerrique Indians are usually well formed, 6 feet 6 inches 106 feet 8 inches tall , and they are active, and appear to be strong and healthy Nevertheless, they are dying out rapidly. Probably not more than 275 or 300 of them are now living. They live in dim pathless forests, and their occupation is to find in the woods various species of trees (Siphonia, Castilloa, &c.) They deeply scarify these, collect the exuding emulsion, and separate the contained elastic ("India") rubber, and this "India" rubber they carry on their backs more than 100 miles to sell to merchants in Rama or at the mouth of Rio Matagalpa They have cleared some patches of ground, and plant corn by making holes in the soil with pointed sticks. They believe that with allied tribes they had in very ancient times a mighty prophet or cacique, who appeared suddenly, full grown, in their territory, and that to him many tribes of Indians gave allegiance. The impalpable form of this ancient chief has been seen by very old Indians proudly walking and gesticulating on the top of Mesa Totumbla. He is buried in, or returns by day to, a deep cavern in this Mesa (a mass of gnesss), and he indicates, by gestures, that he will one day collect the Indians into a great army, and lead them in person to many victories Mr Crawford found his way into the cavern. and discovered in it three cranis of Indians with other bones of their bodies. These were sent in 1880 to the Paris Exhibition. and were afterwards transferred to the U.S. National Museum A few crude beads or ornaments, evidently earlier than the Spanish occupation of Nicaragua, were also found.

THE following are the arrangements for lectures during october at the Royal Victoria Ilali —October 6, Prof 1 Iludoon Beare, the steam engine, with experiments, October 13, Rev Cason Browne, the invasion of hagdand and Battle of Hassings, with illustrations from Bayeux tapestry, October 20, Mr. J. R. Green, flowers and their helpers, and October 27, Rev. E. Bill, the Channel Island

AT a meeting held last year by the students of the Kindergarten department of the New York College for the Training of Teachers, various papers were read on the principles and methods of the Kindergarten These papers have now been stude at one of the educational monographs of the New York College. Miss A Brooks, who contributes an introduction, for the introduction of the Kindergarten yeares into its school, for the introduction of the Kindergarten yeares into its school, and a movement begin by the New York Kindergarten Avocution at desimed, she thinks, "to accomplish great things for the neglected children of the city."

"EGYPTIAN SCIENCE," by N. E Johnson, is the title of a work which will shortly be published by Messrs Griffith, Farran, and Co.

TRE Durham College of Science, Newcastle-upon-Tyse, has issued its Calendar for the season of 1891-92. The College represents the faculties of science and engineering in the University of Durham, and thus constitutes an important portion the University of the north of England. But it does not restrict its work to science and engineering; it fulfils all the functions of a University College.

THE following works will shortly be published by Messes. Crosby Lockwood and Son — "The Mechanical Engineer's Pocket-book of Tables, Formule, Rules, and Data," a handy

NO. 1143, VOL. 44]

book of reference for daily use in engineering practice, by D. Kinnear Clark, "The Metallurgy of Argentiferous Lead," a practical treatise on the smelting of silver lead ores, and the refining of lead bullion, including reports on various smelting establishments, and descriptions of modern furnaces and plants in Europe and America, by M Eissler: "Engineering Chemistry," a practical treatise for the use of analytical chemists, engineers, iron masters, iron founders, students, and others. comprising methods of analysis and valuation of the principal materials used in engineering work, with numerous analyse-, examples, and suggestions, by H Joshua Phillips, "A Handbook of Brewing," a practical treatise for the use of brewers and their pupils, by Herbert Edwards Wright; "Condensed Machines," a selection of formula, rules, tables, and data, for the use of engineering students, science classes, &c , in accordance with the requirements of the Science and Art Department. by W. G. Crawford Hughes, "Milling," a treatise on machines, appliances, and processes employed in the shaping of metals by rotary cutters, including information on making and grinding the cutters, by Paul N Hasluck, with upwards of 300 engravings, "Star Groups," a student's guide to the constellations, by | Ellard (rore, with thirty maps, "Lessons in Commerce," by Prof R Gambaro, of the Royal High Commercial School of Genoa, edited and revised by James Gault, Professor of Commerce and Commercial Law in King's College. Landon

AMONG the books announced by Messis George Philip and Son are the following -"Delagoa Bay its Natives and Natural History," by Rose Monteiro, with 20 original illustrations, after the author's sketches and from the natural objects. by A B and E C Woodward, "Paraguay its History, Commerce, and Resources," by Dr. E Bourgade, with 13 illustrations and a large coloured map, "Makers of Modern Thought, by D Nasmith, Q C , "The Teacher's Hand-book of Sloid," as practised and taught at Naas, by Otto Salomon, Director of the Nats Seminarium, with over 130 illustrations, "Hughes's Class-book of Modern Geography," an entirely new and completely revised edition, much enlarged by J Francon Williams . "Geography of the British Colonies and Foreign l'ossessions," by the Rev. J P. Faunthorpe, new and revised edition, "Systematic Atlas," for higher school and general use, a series of physical and political maps of all the countries of the world, with diagrams and illustrations of astronomical and physical geography, specially drawn by E. G. Ravenstein, "The Handy Volume Atlas of Astronomy," a series of 72 plates, with notes and index, by Sn Robert Stawell Bull, I R S . "The Handy Volume Atlas of London," a series of 64 maps, with notes, compendium, directory, and complete "Atlas of Modern Geography," new and enlarged ındex , edition

THE additions to the Zoological Society's Gardens during the past week include two Macaque Monkeys (Macacus cynomolgus) from India, presented respectively by Mr G. H. Sas-e and Mrs Gregorey; two Sykes's Monkeys (Cercopithecus albigularis) from East Africa, presented by Mr. F Pardage, one Mozambique Monkey (Cercopithesus sufo viridis), one Garnett's Galago (Galago garnetts) from East Africa, one Blotched Genet (Genetta (1.72 ma), one Ostrich (Struthio camelus) from East Central Africa, presented by Mr. Freith Anstruther, one Coypu (Myopotamus coypus) from South America, presented by Mr Spencer H. Curtis, one Golden Eagle (Aquila chrysacius), European, presented by Mr Herbert Bray, one - Sand Grouse (Pterocles ----) from South Africa, presented by Mr. Max Michaelis; two Trocary Pigeons (Columba trocary) from Madeira, received from Dr F J Hicks; one --- Elap: (Elaps ---) from Australia, presented by Mr E II. Meek,

one Rhomb-amarked Snake (Psammophis shombeatus), four Crossed Snakes (Psammophis crucifer), one Hygian Snake (Elaps hygra), two - Snakes (Dasypelts: scabra) from South Africa, presented by Messrs Herbert Melville and Claude Beddington: one Smooth Snake (Coronella lanus), two Common Snakes (Transianatus natrux) from Oxfordshire, presented by Mr A W. S. Fisher, one Otter (Lutra vulgaris) from South Wales, received in exchange, two White-iailed Sea Eagles (Haliačius albicillay's) from Norway, three Indian Python (Python molurus) from India, deposited, one Macaque Monkey (Macacus cynomolgus) from India, one Pardine Genet (Genetta pardina) from West Africa, purchased, one Vinaceous Turtle Dove (Turtus sunaceus), heed in the Menagerie.

OUR ASTRONOMICAL COLUMN.

LIGHTNING SPECTRA -Mr W E Wood, of Washington, LIGHTNING SPECTEA—Mr W E Wood, of Washington, has continued his observations of lightning spectra for the purpose of determining the origin of some of the lines previously recorded by him (NATURE, vol. xlu p 377). The results is that he is now able to say, in the Suderal Messenger for August : he is now able to My, in the Suderal Messenger for August p-"Lightining spectra present but the characteristic lines of oxygen, hydrogen, nitrogen, and earbonic acid, and—what was puzzling to me—the line of the vapour of sodium. The absorp-tion bands which I find in lightining spectra. I think might be produced by the moisture in the air, a large quantity being present during thunderstorms." It is suggested that the sodium line owes its presence to the existence of meteoritie dévirs in the atmosphere

A NEW ASTEROID. -The 315th asteroid was discovered by Charlos on September 1.

THE INTERNATIONAL GEOLOGICAL CON-GRESS WASHINGTON MEETING

THE fifth meeting of the International Geological Congress, being the first ever held in America, was held at the Columbian University, Washington, from August 2610 Septem ber 1, with an attendance of axxy or seventy foreigners, from Austria-Hungary, Canada, Chihi, France, Germany, Great Britain, Mexico, Peru, Rosmania, Russia, Sweden, and Switzerland, and about two hundred members from the United States The papers and discussions were generally in English, though French and German were to some extent spoken. French has

been the language of all the previous Congresses

Profs James Hall and James D Dana were elected Honorary Presidents, and J S Newbery Acting President Owing to the absence of the latter, the chair was filled in turn by everal of the Vice-Presidents

FIRST DAY—After the election of officers, as nomunated by the battern, Frof Joseph La Conte, as senior Vice Fresident, the state of the content of the conte afterwards carried out-manely, to discuss classification of the Pleutocome rocks, of correlation, and of map notation. He pleutocome rocks, of correlation, and of map notation. He pleuty of the former and the simplicity of the latter. He then considered some points in American geology—(-i) The general continuity of the record. (3) The prevalence of exercise continuity of the record. (3) The prevalence of exercise continuity of the record. (3) The prevalence of exercise continuity of the record. (3) The prevalence of exercise continuity of the record. (3) The state of the record of th uptilted strata. The Sterra Nevada is an illustration. (4) Ex-tensive lava floods, covering areas from 10,000 to 100,000 square miles in extent, and from 2000 to 4000 feet deep No such floods are found elsewhere. Those of India are the nearest approximation, but in Europe the lava beds are small and much cut up. (5) The great continental movement, commencing in the later Tertiary, and terminating in the beginning of the Onternary, which has caused changes of level amounting to 2500 or 3000

feet on both sides of the continent (6) The ice-sheet of the glacial feet on both sides of the continent (6) The ice-sheet of the glacuit open was first and most completely demonstrated in America.

Oher addresses were delivered by 8th, Ziubbart, Charman of the soft of the control of the special control of the special control of the special control of the Coological Survey of the United States; Prof. Hughes of England, Prof. Gaudry of France, and Mayor Powell, Chief of the Geological Survey.

SECOND DAY—The entire by wes eccepted by a fusions on elamification of the glease II between deposits. Prof. T. C. Chamberlin opened the discussion by stating that classification might he made on three grounds (1) structural, (2) chronological; (3) genetic. The first was very easy, being an obvious extremely difficult, and could not be accurately made till after a full determination of the third. He accordingly proposed the following general classes: (1) formations produced by the direct action of Pleistocene glaciers; (2) formations produced by the combined action of Pleistocene glaciers and accompanying durest action of Pleutocene glacers; (2) formations produced by the combused action of Pleutocene glacers and accompanying glacuit formage; (3) formations produced by disease accompanying glacuit formage; (3) formations produced by those accompanying produced by douting ice derived from Pleutocene glacers; (5) formations produced by shore acceptance according to the Pleutocene temperature, but independent of glacers action., (6) glaco-divarial deposits under the peculiar conditions of glacuiton. This paper was decussed very throughly Frof T McK Hughes pointed out that the classification suggested by Frof T McK Hughes pointed out that the classification suggested by Frof T McK Hughes pointed out that the classification suggested by Frof and the superior of the control of the c

preting geological processes. Any primary geological classifica-tion must be genetic lle discussed in detail the following scheme of classification of Plestocene deposits -

Classification of Pleistocene Formations and Land Forms A. Aqueous

- Below base level. Marine
- b Estuarine Lacustral
- 2 At base level a Littoral b Marsh
- Alluvial (certain terraces, &c)
- 3 Above base level
- a Torrential
 b Talus (including playas).
- I Direct (Chamberlin's Class I) 2 Indirect (Chamberlin's Classes II to V., in part).

 C Aqueo Glacial (Chamberlin's Classes II to V., in part).

 D. Folic (Chamberlin's Classes II to V., in part).
 - Volcanic 1 Direct
 - a Lave sheets b Cinder cones
 - Tuffs, lapilli sheets, &c.
 - 2. Indirect
 - a. Ash beds b Lapilli sheets
- Prof Chamberlin, in closing the discussion, said that there was great difficulty in applying a chronological classification, and that such a classification might even act as a barrier to observation and to the recognition of the truth. Chronological classification is the ultimate goal of glacial studies, but it is something for which we are not as yet prepared. Red, outdated sub-soils are not developed in northern latitudes. Organic deposits between glacial layers are abundant in the West, but do not belong to a single horizon. Many facts of crosion and

physical geology indicate that the Glacial epoch in America was widely differentiated and of long duration How many distinct periods it embraced we do not as yet know Prof. Cope said an abundant tropical fauna is found in the "Equius beds," which, if they be of interglacial age, indicates at

this time a very warm climate. This fauna is succeeded by a truly boreal fauna. In this is contained material for a chronological subdivision of Pleistocene deposits

THIRD DAY -The President announced as the subject for discussion, the correlation of geological formations. Mr Gilbert opened this discussion by presenting a general

classification of methods of correlation Strata are locally classified by superposition in chronologic sequences. Geologic correlation is the chronology of beds not in visible sequence For convenience in discussion, methods of correlation are classed in ten groups, of which six are physical and four biotic

Physical Mitheds of Correlation

(1) Through visible continuity. The outcrop of a bed is traced from point to point, and the different parts are thus correlated one with another. (2) Strata are correlated on account of hthologic similarity

This method, once widely prevalent, is used where the distances are small (3) Correlation by the similarity of lithologie sequence h

great and important use where the localities compared fall within the same geologic province, but is not safely used in

within the same geologic province, but is not sarely used in passing from province to province (4) Physical breaks, or unconformities, have a limited use, especially in conjunction with other methods. The piactice of employing them in the case of localities wide apait is viewed ith suspicion.

(5) Deposits are also correlated with their simultaneous rela-

(3) Jeponis are asso coreined with their similarity and physical event—for example, a breach with the temperature of the physical event—for example, a breach with the sahaqueous deposit, and alluvial, intorial, and subaqueous deposits standing in proper topographic relation. In the Plentocene, glacial deposits are widely correlated with reference to a climatic episode assumed to arise from some general cause.

to a climatic episode assument to arise from sourc general cause (6) Deposits are correlated through comparison of changes they have experienced from geologic processes supposed to be continuous Newer and older drift deposits in different regions are correlated according to the relative extent of weathering are correlated according to the relative extent of weathering and erosion, induration and metamorphism afford presumptive evidence of age, but yield to evidence of other character. Meta-morphism holds prominent place in the correlation of pre-Cambrian rocks where most methods are mapplicable.

These physical methods are qualified by the geographic dis-tribution of geologic processes of change and of geologic

Biotic Methods of Correlation

(7) A newly-discovered faims or flora is compared with a standard series of faunas and floras by means of the species it holds in common with them severally (8) It is also compared by means of representative forms, or

through genera and families

(7a) and (8a) These comparisons are strengthened if two or more faunas in sequence are found to be systematically related to

the faunas of a standard series. (9) Two faunas or floras otherwise related are compared in

age through their relation to the present life of their localities.

This method was applied by Lyell to Tertiary rocks

(10) Faunas are correlated by means of their relation to character suredes their relation to chmatic episodes taken in connection with station. For ex-

climatic episodes taken in connection with station. For ex-sample, boreal shells found in latitudes below their present range are referred to glacial time In general the limitations to accurate correlation by biotic methods arise from the facis of geographic distribution. Cor-relations at short range are better than those at long range.

relations at short range are better this those at long range. Blotte correlation by means of fossils of different kinds may be a superior of the state of the sta

NO. 1143, VOL. 447

unimportant Among animals, those which are marine, lacus-trine, and land animals may be distinguished. Of these classes marine invertebrates are most valuable for purposes of correlation. The vertebrates change rapidly, but are frequently altogether wanting For instance, no vertebrates occur in the Alpine beds corresponding in age to those which contain the mammalian fauna of the Paris basin. In certain lacustrine deposits invertebrates may be absent, and in such cases the

vertehrate fauna is the surest guide

Baron de Geer emphasized the importance of a numerical comparison between different species The actual counting of

individuals in a given formation is of great value

individuals in a given normation is of great value. Prof. Marsh expressed his agreement in general with the conclusions communicated by Prof. von Zittel, but would give special weight to vertebrate fossil. In the Mesozoec and Tertiary beds of the Kocky Mountains he had found that the vertebrates offer the aurest guide for correlation. This is in part because invertebrates are either wanting or are lacustrine most characteristic vertebrate genus in each which is confined exclusively to it. He presented in outline of such classification brought down to date, with a section to illustrate vertebrate life in America

Mr C. D Walcott spoke of the value of plants for purposes

For general correlation

of geologic correlation
Prof T, Mck Hughes spoke of the present and growing tendency towards a natural classification
The evidence is com-

tendency towards a natimal dewification. The evidence's com-plex, and includes v considerable warmey of diverse relations and the property of namony are cited an example from his own experience, or how an identification of synchronous formations might be made over a wide area through a union of physical and hotic

ernous Mr W J McGee remarked that in the coastal plain of the United States physical correlation alone is employed. The bases accord with those outlined by Mr. Gilbert, with certain minor modifications and an important addition, as follows—

Visible continuity For local discrimination Lithologic similarity . Similarity of sequence Physical bicaks viewed as inand correlation For correlation throughdices of geography and topoout the province graphy Relation to physical events, including continental move For correlation with conments. tiguous provinces transportation of materials, land sculpture, &c

Homogeny or identity of origin

By correlation upon these bases the physical history of a considerable fraction of the continent may be so definitely asceratained as to permit fairly accumite mapping of the geography, and even the topography of each episode in continent growth After these episodes are clearly defined, and the fossils found in the formations are studied, it will be possible definitely to as-certain the geographic distribution of organisms during each episode, then palmontology may be placed on a new and eprsode, th higher plane Prof. W.

higher plane Prof. W. M. Davis showed that it was possible to decipher geological history not only through the records of deposition, but also by processes of degradation. As an example of this method he explained a topographical section from the city of New York westward. In this we have evidence of the existence New York westward. In this we have evidence of the existence of an ancient jeens/tain, or base-level lowland of Cretacous age. This surface was subsequently elevated (more toward the west than toward the cast) at the end of Cretacous, or at the beginning of Tertiary time. It has since been dissected by the excavation of more recent valleys. The Iludson Valley lowland was cited as on example of this recent dissection

Prof E. W Claypole considered that the different methods of geologic correlation differed very greatly in their value. It is improbable that the plant or mammalian record will ever equal in its perfection that of the marine invertebrate fauna. The marine fauna is to the geologist what a primary triangulation is to the geodesist It marks out the main divisions, which are subsequently further subdivided through the aid of other fossils.

such as plants and vertebrates

Prof C. R. Van Hus spoke of the methods of correlation employed for pre-Cambrian rocks, which occur in widely separated areas and are devoid of fossils. Physical data only are available for correlating these formations Experience has are available for correlating these formations. Experences has belown that, among all physical methods, unconformity us by far the most important. Other physical enteries, such as the edge which is the most important. Other physical enteries, such as the edge which is the substitution of single areas, but cannot be safely used in identifying synchronous formations in widely expected used in identifying synchronous formations in widely expected of geological gas that tested the screenite substitution of pre-Cambrian rocks. The researches of Pumpelly and other in the eastern United Stites have demonstrated that Shirman, Devonian, and even Carboniferous deposits might become, Devonan, and even Carboniterous deposits might become, under certain physical conditions, as highly crystalline as much more ancient rocks of the West For this reason it has been found necessary to abandon such terms as Huroman and Armennanan Evidences of life are not lacking in pre-Cambrian rocks, and it is to be hoped that the paleontologist will succeed in differentiating several separate formations below the Cambrian, as the Cambrian itself was differentiated from the base of the

FOURTH DAY -Prof L W Hilgard laid stress upon the importance of the abundance or scarcity of species in the importance of the abundance or scarcity of species in the correlation of strata. He thinks some quantitative estimation of the species should be made. He is of the opinion, also, that, as compared with insurine fauna, plants have but little value for purposes of correlation owing to their local distribution, their accidential proximity to water, transportation, and preservation. Plants can be so used only after large areas are worked over. Prof. Lester F. Warl continued the discussion. It de-

weloued two of the more general principles of correlation by means of fossil plants, as follows —

(1) That the great types of vegetation are characteristic of the

great epochs in geology This principle is applicable in comparing deposits of widely different age when the stratigraphy is indecisive. For example, even a small fragment of a Carboniferous plant proves conclusive. sively that the rocks in which it occurs are palæozoic, or a single dicorvledonous leaf proves that they must be as late as the Cretaceous

(2) That for deposits not thus widely different in age, as, for example, within the same geologic system or series, ample material is necessary to fix their position by means of fossil

Neglecting this principle has led to the greater part of the mistakes of palacolotanists, and has done most to bring palacobotany into disrepute. (reologists have expected too much of them, and they, in turn, have done violence to the truth in them, and they, in turn, have done violence to the truth in attempting to satisfy extravagand demands. On the other hand, where the matterial is ample, fossi plants have often corrected the mistakes of strattgraphical goodquits, and solved problems concerning geologic age, which seemed impossible of settlement by any other class of evidence.

Prof. Henry S. Williams land stress upon the relations of species to the conditions of deposition.

species to the condulous of deposition. The abandance of a species wares with environment, and a study of correlation should embrace a study of these condutions. Sendatones deposited near short may have a faunt different from that of a family and the study of the conductions are short may have a faunt different from that of a family and the study of the conduction. The age of beds should be determined by comparing species of the same genera rather than by comparing those of different genera. There are centered shandance which exhibit great variability in their characters; outside of these centres the species exhibit varieties which may be called extralimital, and which are not typical though they have often been

published as types.

Prof. Charles Barrois said that there was no general basis, either biologic or litherogic, for the correlation of the pre-Cambrian rocks of Europe with those of North America; even the terms applied to these rocks were liable to be misanderstood. divisions used in France cannot be correlated with those now used in the United States General correlation cannot, as vet. used in the United States General correlation cannot, as yet, be hased upon nonconformittes; autopay is the only basis upon which a comparison can be instituted. He pointed out certain parallelsms. Fetween the histories of the crystalline schists of America, as illustrated by Mr. Pumpelly, and the guesser rocks of Brest, where the Cambrian slates are altered to gneisses of Archavan aspect, while the alternating fossiliferous quartzites archanged to crystalline quartz. Geologists must see the beds together in order to reach a common understanding of the crystalline rocks

Prof E. D. Cope discussed the question from a general point of view with especial reference to the value of vertebrates for purposes of correlation, particularly for inter continental correla-tion. He pointed out that there is a marked difference in the tion He pointed out that there is a marked difference in the present verebrate faunas of continents, and that the variation of such forms must be sought in vertical rather than in horizonial ranges. Such study shows that we have had invasions of a given region by a fauna from without; for example, a South American fauna invaded North America at one time and then retreated, while a North American fauna once invaded South America, and traces of it still remain in that country He is in-clined to believe that certain vertebrate forms did not spread over the earth from a single place of origin, but that originated at different places upon the earth We have parallel-ism in separate places, but the parallelism is defective in the I aramie

Mr G K Gilbert was of the opinion that many methods of correlation must be used. He doubted the trustworthiness of the He thought the abundance and scarcity of fossil forms comparable with lithologic differences, and considered the simple occurrence of a species as valuable for purposes of correlation as its abundance

FIFIH DAY - Subject for discussion map-colouring and cartography.

Major J W Powell exhibited charts illustrating the colour system used by the U S Geological Survey, explained the methods of using the colours, and gave the reasons for them

7	he	colours assigned to	rocks of different ag	es are as follows
		Period	Penad colour	Mark
	1	Neocene	Orange	N
	2	Eocene	Yellow	E.
	3	Cietaceous	Yellow green	K
	ă.	lura-Trias	Blue-green	1
	5	Carboniferous	Blue	ç
	ŏ	Devonian	Violet	D
	7	Silurian	Purple	Š
_	8	Cambrian	Pink	€
•	9	Algonkusn	Red	Ã

The colours are used to designate geologic periods, patterns The colours are used to designate geologic periors, patterns of these colours designate formations; minor divisions are designating formations can be indefinitely enlarged, but follows a designating formations can be indefinitely enlarged, but follows a definite system.

Mr Joseph Willious showed that in the scheme described by Major Powell the colours were not evenly dustributed through

major rowen in colours were not evenly diarnoused inrough the chromatic scale. Prof C. R. Van Hise pointed out that Archean rocks are shown by a brown underprint, and that metamorphic rocks of known age are given the colour of the corresponding unaltered

Major Powell explained that it was not attempted to select

Mayor Powell explained that it was not attempted to select-closurs equally distributed through the chromatic scale, but to down sequely distributed through the chromatic scale, but to Mr. II. M. Cadell asked why black and gray were not used, Mayor Powell replied that bute was used in place of the dark shades for the Carboniferous; that dark colours are milledning and the colours are milledning to the colours and the colours are sent and colour and Textifury as well as in the Carboniferous, Mr. Chrostife found the black colour very inconvenient, because offers made the details of the map covered by such colours offers made the details of the map covered by such colours

illegible
Mr. H. M. Cadell said that the maps of the Geological Survey of Great Britain were coloured by hand, and that the system used by the U S Geological Survey could not for this reason

Major Powell explained that the U.S. Survey system is very conomical when the colour patterns are transferred to atones. Prof. T McK Hughes thought it very difficult to devise a scheme that will meet the demands of everyone. Some refe ence must be had to the permanence of the colours, the readi-ness with which they can be applied, and the distinctness with which they show what is desired. He thinks the fittest scheme must envenue

In the afternoon, hrief lectures were given by Prof Chamber lin, Mr Gilbert, Major Powell, and Mr Emmons upon the geology of the country to be traversed by the long excursion

SIXTH DAY -A Committee on International Bibliography

was appointed.

The Secretary announced that Messrs, Golier and Schmidt convey an invitation from the Swiss Government to hold the sixth International Congress, in 1894, in Switzerland, Mr Golier delivered an address in which he presented the invitation, Goher delivered an address in which he presented the invitation, and the Congress unanimously accepted it. The following Swiss members were appointed a local committee, with power to add to their number and to appoint the time and place of meeting viz. Menzer Heim, Renevier, Lang, Balter, Schmidt, and Golier On the motion of Prof Purpuelly, a vote of thanks was passed to the Swiss Government and delegation. It is thought that Berne will be selected as the place of meeting

The Geological Survey of Russia sent an invitation to hold the seventh Congress in Russia. The Car joined in the invitation. Prof. Tschernychew made the formal presentation of the tion. Prof. Tschernychew inside the formal preventation of the subject to the Congress. A vote of thanks to the Survey and the Car was passed, and the Secretary of the Congress was authorized to send a despatch by cable, transmitting the vote. The President of the Congress, Prof. 1 e Conte, delivered a

brief closing address, summarizing the work of the session, and after passing several votes of thanks the Congress adjourned

THE SOCIETY OF FRIENDS OF ASTRONOMY AND COSMIC PHYSICS

THE Society of Friends of Astronomy and Cosmic Physics founded May 19, 1891, has been formed with a view to the organization of systematic activity and co-operation in research in the subjects named It is mitended to embrace, chiefly, workers in astronomical science in Germany, Austro Hungary, Switzerland, and other neighbouring countries, and natives of these countries in the colonies and elsewhere Members of other nationalities are, however, offered a welcome

The head centre of the Society is Berlin. The subscription

The head centre of ine 50-tery is never an experience of the formal form

not be issued at regular or stated intervals.

These communications will form at present the only direct publication of the Society, until it is formed on a more substantial financial basis and consists of a larger number of members (in the first four weeks the number rose from 50 to over 100) Contemporaries are at liberty to horrow any matters of

too) Contemporares are at liberty to horrow any matters of interest contended in the Society's communications, of course acknowledging the source from which they are derived acknowledging the source from which they are derived as the source of the Meteorological and Photographic Societies, but, never theless, endeavouring to preserve the closest annity and co opera to with the relief Societies.

The Astronomische Gesellschaft, founded in Germany in 1863, is regarded by the new Society as the principal Society, whose office it is to loster astronomical research throughout the whole earth. The new Society bears the same relation to this international association as do those Astronomical Societies already established in England, France, Russia, and North

The principal object of these smaller societies is to collect observations made in the largest possible number of districts, inasmeet as researches in astronomy and cosmic physics are very largely dependent on the state of the weather, and the relation of the place of observation to the phenomena in the heavens.

In the new Society the following branche, of work have been selected:—(1) Observations of the sun; (2) of the moon and selected:—(2) Observations of the sun; (3) of the moon and selected:—(2) Observations of the sun; (2) of the polar of the selected selec

respondence, noted brance meetings, and preserve the connection which bunds each group to all the olbers

The Society will sendeavour to further the organization of all these researches, not merely by the publication of communications and by correspondence, but also by advice and aid in the providing of Apparatius, expectally of sinishes optic, electric, and

The statutes of the Society will be sent post free on applica-tion to the Secretary, Herra Cand C Witt, Berlin, N.W.,

A MONGS1 a gathering of small Serpulids, &c., received from Mr. Sinel, of Jersey, I find some interesting little worms related to the Sabellida. They build a thin membraneworms related to the Sabelinds. They build a thin membrane-like tube, about one seventicth of an inch in diameter, coaled externally with flat translucent particles of sand. Its lower end externally with flat translucent particles of sand its lower end is closed, and embedded in sponge or other growths, but the upper end is free, and, when the head of the inmate is protraited, stands about a quarter of an inch high in the water. On this head are two branching tuffs, each having five branches. based with a double row of long clinated hizments. When all are fully expanded they curve backwards, and cover an area of about one tenth of an inch in diameter. The hranches decrease in size from the inner to the outer pairs, and at the back of the longest but one in each tuft, near its base, is a chocolate or

brown coloured vesicle. The two smallest branches curve back-wards round the mouth of the tube, and keep up a constant

wants found the mouth of the tupe, and keep up a constant whipping of flicking motions, upon the retreat of the animal, the mouth of the tube not only instantly closes flaily and tightly collapse of the sides, but the tube tittle, beginning at the tup, proceeds to coil up like a spiral spring, looking very much like a young Fern-found. This y, of course, an effectual protection against the intrusion of enemies, and the coiling and uncoiling, which I have witnessed many times, is a most curious

Fig. 1 shows the branchial tufis expanded Fig. 2, tube beginning to coil up. Fig. 3, tube partly coiled up—a process which is

sometimes continued much further. I do not know whether this annelid has previously been noticed or described, but, if so, I shall feel obliged to any of your readers who can refer me to ARNOLD T. WATSON. Sheffield, August 10

GEOGRAPHY AT THE BRITISH ASSOCIATION.

THERF was at least one very satisfactory feature about the Geographical Section at the Cardiff meeting. It has been the practice in all the other Sections to appoint as Presidents men who have gained a high reputation as specialists in their own wno nave gained a high reputation as specialists in their own departments. For some remon this practice has not been followed in the Geographical Section True, in past years we have had such men as Murchison, Markham, Galton, General J. T. Walker, but too often the President of this Section, while em-Walker, but too often the President of this Section, while emi-nent as a soliding or a colonial Covernor, or as a Society man, has known as much about geography as "the man in the street". It must be admitted that this has in part arisen from the fact that scientific geographers in England could have been consided on the fingers of one hand. Happily, through the recent efforts of the Royal Geographical Society, thriving to be the case, and when the Chairs at Oxford and Cambridge, and the other in-fluences which are at work, have had time to produce results, fluences which are at work, have had tune to produce results, geography, non ore often of its aspects, may become as much of a career in legisland as it is in Germany. If was regarded as to one cettent a trumph, and an exercise of what is coming, that the President of the Section at Candiff was a geographer pure the conscientific configuration of the Section at Candiff was a geographer, and the conscientific configuration of the Section at Candiff was a geographer, in the conscientific configuration of the United Kinglion (where he has been naturalized for many years), and in a geographer, in the best sense of the term, he is not surpassed. If was natural that in his address, he should deal with the progress of the subject in which he is master. If his address, which contensibly supect in which he is master. His address, while ostensibly dealing with eartography, really showed the growth of our coception of the earth's surface, and indicated the most profitable aspects in which we may deal with that department of knowledge whose business it is to investigate dge whose business it is to investigate

Amid a good deal that was trivial, and not withstanding the

isual modicum of sensation, Section E did some solid work at Cardiff The fact is that the only incident which could be Mrs. French Sheldon and the appearance on the platform of regarded as sensational was the appearance on the platform of Mrs. French Sheldon, evidently suffering greatly from the accident with which she met on her return from Klitmanjaro But Mrs. Sheldon was able to tell us some things about the people in Last Africa that had never come within the ken of the male traveller Moreover her account of the curious crater lake male traveller Moreover her account or the cursous craser saxe Chala, at the south-east foot of Kilmanapro, was a real contribution to geographical knowledge. With immense difficulty abe and her companion descended the denne vegetation which covers the precipitous sides of the crater, and navigated the tray lake on a raft, which was continually in danger from the awarms of crocodiles. Mrs. Byshop (Miss. Isabella Brd) was anything crocodiles Mrs Bishop (Miss Isabella Bird) was anything but senational. With perfect calmines and clearness she gave obtained to the control of the control

Mr. John Coles's paper on the art of observing showed how Mr. John Coles a paper on the next of conserving snowed now comparatively easy it is for any man of average intelligence, and even punit in the higher classes of our schools, to acquire a knowledge of the use of the more common survey instruments. An excellent paper on the homology of continents was read by Dr Hugh Robert Mill, who showed that in many respects to by Dr. Hugh Kobert Mill, who showed that m many respects there as a generakable family likeness among the continents, there is a general continent of the same influences. Mr. Silva White, in his paper on the comparative value of African lands, attempted, by a statistical method, to indicate the lines of least resustance against the European domination in Africa. Mr. Miller Christy gave an elaborate and highly instructive paper on the absence of trees from prairies, his conclusion being that the main cause of the treelessness of American prairies has been forest fires. The paper was highly suggestive, showing, as it did, that if proper measures were taken were nour great deserts might be made to blossom as the rose

The greater part of one morning was devoted to a discussion

on acclimatization, introduced in a valuable paper by Dr Robert Felkin. The author showed that there are two schools of thought, the one regarding acclimatization as impossible, the other more sanguine and pronouncing it possible. Probably the truth will be found to be a mean between the two. In considering the subject, it is necessary to specify, first, the various nations who are to be acclimatized, and secondly, the places where they are to be located. As regards the first point, the national characteristics, habits, customis, and environment insuit be taken into account, and with respect to the second, the nature of the country, its climatology, its inhabitants, their mortality and endemic diseases must be brought under survey. The next point is to classify the various European nations, and it becomes evident that they can only become readily acclimatized in the national characteristics, habits, customs, and environment must temperate zone, where climatic and other conditions are approximately ikin to their present habitat. In reference to Europeans becoming acclimatized in the tropics, what are those factors becoming acclimatized in the tropics, what are those factors which prevent it, or which must be overcume before its possible? They are as follows hest, cold, damp, various endemic discusses, expectably maintain, and those constitutional conditions discussed in the control of rendering acclimatization possible for Europeans in tropical countries? It must be said that both Dr. Felkin and those who followed him in the discussion occasionally lost sucht of the real point at issue The adaptation of a European to tropical conditions for a few years is one thing, the acclimatization of a race in a climate totally different from that which has been its inheritance is another. About the former there need be now no difficulty what scanty experience we have leads to the con-clusion that the latter is practically impossible. What we really want are experiments continued over three or four generations

generations
Colonel Holdich, of the Indian Survey, gave some valuable
hints in his paper on the application of Indian geographical
survey methods to Africa An outline of the methods proposed
may be summarized as—(1) The adoption of a rapid system of may be summarized as—(1) The adoption of a rapid system of trangulation along the most important lines for first survey (2). The extension of a graphic system of mapping from these lines of the proposed of the state of the sta respect, though there may be no mmediate cause for action. There is, however, a great necessity for a topographical acquantance with the boundaines adopted. Only a small portion of being defined by rivers, &c. If would appear, then, advantageous to commence transgulation along the boundary lines thus; however, to far a national or international question, and ance might very well be expected, and Imperial resources drawn upon for enzying it out. (1) What are there resources? (2) What is the nature of the survey we ought to bindly 197. Replying to (3) and (3), we find that if a continuous and comprehensive scheme is to be adopted, with unity of design for all the been done as yet which would least that it is not to be more of the continuous and comprehensive scheme is to be adopted, with unity of design for all the been done as yet which would least that necessarily out or the continuous and comprehensive scheme. respect, though there may be no immediate cause for action. scattered distracts of the African colonial system, nothing his been done as yet which would assait as in carrying out our scheme. This scheme should be largely borrowed from expe-sion of the same as the same as a second of the same as to what extent largerial survey resources might be atlined during the processes of laying out the preliminary lines of transquistion. From this transgulation the extension of looperably would there-after probably depend on private enterprise. Then followed a carried out by astress of I float, of the value of such native labour, and of the possibility of rasing survey establishments!

The subject of reform in our Ordnance Survey was again introduced this year in an elaborate paper by Mr. H. T. Crook, who was strongly supported by a number of speakers. Mr Crook pointed out many defects in the large-scale maps. Some of them are notoriously behind date; they are issued in a most

inconvenient form: they are far too expeasave, they are difficult to obtain notated of London. The Committee of this Section sent a strongly worded resolution to the Council of the Association, recommending, among other things, that the Directorship of the Suivey, instead of being merely a staff appointment, should be made a permanent office. Unfortunately, the resolution submitted to the General Committee omitted this remaining the committee of the Committee o

amount to much

Mr James Thomson's paper on photography applied to
exploration contained suggestions of great practical value. He
showed the value of the camera, not only in recording geographical
features and types of people, but even as an adjunct to regular

The subsect of geographical education was introduced in a short paper by Mr. J. Scott. Active, who no pole of the results which had followed the action initiated by the Royal Geographical Society a few years ago. Advances have been made in many directions. Chairs have been established in Oxford and eliminate of the subsection of geography and of its contraction of the subsection of geography and of its contraction of the subsection of the s

MECHANICS AT THE BRITISH ASSOCIATION.

N Section 6, Mr. Secreta Brown.

N Section 6, Mr. Secreta Brown.

In the locality are the secretary and the secretary with the president. There was an average list of papers, but the discussions were not so fall as as sometimes the case in this Section. As a consequence, the attituge were got through with more than whole bisumests of the Section 4 as consequence, the attituge were got through with more than whole bisumests of the Section was completed by two of other on the Tuesday of the meeting. The President's address was given as usual on the Thursday, and referred to mechanical details in connection with mining. In character with the meeting it would not be seconded, Prof. Obsborne Reynolds proceeded to reed the third Report of the Committee appointed to investigate the action of waves and currents on the both and forebitors of estuaries by developed the committee around the second to the second the second of the committee appointed to investigate the action of committee around the second to the second of the second o

experiments, more especially without the also of the congruence with the Report was illustrated with the Report was illustrated with the Report of the Report of the Report of the Report of the Stevenge of a neighbouring district, and thus relieve the River Eaff of some of its present fool buries. The sever, no doubt, is a mentronous engineering notable point as that the Taff has to be crossed severe times, and thus as effected by means offmerted syphons which go below the river bed. The principle, of course, is not new The chief interest was in the speech made by Mr. Baldwin Laban druing the discussion, in the course of which the spraker esclaimed the sarth should be returned to the earth Mr. Latham is of opinion that what is taken from the earth should be given to the sea. The occase, he says, was given to the enquerer as a

receptacle of sewage—presumably among other functions. Moreover, Mr Latham tells us that it is more profitable to put sewage in the sea than to keep it on the land. It encourages the growth of marine fauna, and it is, so Mr Latham says, a well known fact that where there is most sewage there are most fish. As there were no "faddrits" present, Mr Latham had it all his cays was.

courage the growth of marine fauna, and it is, so Mr Latham says, a well known fact that where there is most swage there says, a well known fact that where there is most swage there Latham had it all his own way.

Mr L F Vernon Harcourt's speep described the engineering operations carried on in the neighboring River Usk and the harbour of Reveryor. This pass, gain, did not him forward harbour of Reveryor. The pass again, did not him forward necessing on the now fairly well recognized lines of increasing the third fact. The Athernethy spoke in the discussion, and fold the total flow. Mr, Athernethy spoke in the discussion, and fold the

any points of partnealar novelty. Mr. Vernon Harcourt is proceeding on the now fairly well recognized linas of increasing, the total flow. Mr. Abernethy spoke in the discussion, and told the Section how he had once resigned his position in connection with the Swannes Harbour Board because it was proposed to canalate the river. The question might, we think, have been contained the river. The question might, we think, have been with the proposition of the proposition of the contraction of the work of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proton of the proposition of the proposition of the proposition of the proton of the proposition of the proposition of the proposition of the proton of the proposition of the proposition of the proposition of the proton of the proposition of the proposition of the proposition of the proposition of the proton of the proposition of the

Prof. W. Robinson next read a paper on petroleun engines it would appear that this description of motor is hiely to come to the front, if one may judge from the fact that their manifacture is being taken up by some important engineering firsts. Priestiman Brow, of Itali, have been at work on the problem for the last year or two, and it is chiefly of the Prestiman engine that Prof. Robinson speaks. Croseley Bros., of Manchester, who have made such a brilliant success with the Otto gas engine.

have now taken up the subject, and are making an oil engine; whilst the big agricultural engineering firm, Hornsby's, of Grantham, have also turned their attention in this direction. Grantham, have also turned their attention in this direction. There have also been efforts under by foreign engineers. A petroleum engine works generally on the same principle as a gas engine, but the chief trottle, we believe, hitherto has been to get over the clogging of parts. This supplies the chief feature in the Priextuan design, in which there is a spray maker specially designed to get over this trouble. A jet of oil is fair. broken up by compressed air, and the spray is then further mixed with air, heated by the hot products of combustion. To mixed with air, heated by the hot products of combination. To cleanance the air it is drawn through cotton wood, which naturally has to he renewed from time to time. The proportions of air and oil vapour rea earranged to give an exploitive charge, and a regular explosion is obtained every cycle by means of an electric spark. The cylinders are water-jucketted. Messar, Priesman have fitted a pair of their oil engines into a small launch, which is said to have answered well. Whether pertoleum used with the proposed of the control of the contro explosively in an engine affoat will ever our tried but very imperfect servant steam-as the gas engine is superseding the deam engine in so many positions ashore—is a very open question. Certainly it is a great temptation to get rid of the heavy and bulky boiler, which takes up so much room in a boat, but much remains to be done before we can arrive at the more logical method of generating heat energy in the place where it has to be used — It may be that that terrible exhaustion of our has to be used It may be that that terrible exhaustion of our coal-fields, about which we heard so much at the meeting of the Association, will be indefinitely postponed by the using of petroleum or other hydrocarbon as a source of motive power. But that is another story

Mr. Beauchamp Tower described some improvements in de-tail which he has introduced in the design of that beautiful piece tail which he has introduced in the design of that beautiful piece of mechanism by which he has severale to us, by means of gyrocopically controlled hydraulic gear, a steady platform at rea, power by compressed air D. William Anderon described his revolving water punifer, and Mr. Faija gave a long account of many joints in connection with Portland cement. These were all the papers read on Finday.

On Saturday there was to meeting in Nection G, and Monday of the paper of the papers of the

was, according to custom, devoted to electrical matters. Mr W H Preece opened the proceedings with a long paper, or rather lecture, on the London and Paris telephone, in the course of which he was enthusiastic upon the success which had been obtained. He is sanguine that before long we shall be able to talk between London and Berlin. Of course, he improved the talk between London and Berlin Of course, he improved the occasion by invisting on the necessity of metallic returns, a point upon which all will agree with him except shareholders in tele-phone companies Naturally, also, Mr Preece did not fail to hint how much better off the British public would have been had telephone exchange been left in the hands of the Post Office No doubt, if all the telephones were now transferred to Mr Preece's guidance, we should sooner have metallic returns, and Christian patience would be less exercised, but the question may ause whether we should have had any telephones at all now if Covernment monopoly had not been broken through Mr Preece as the controlling factor, we should answer "Ye But there are other sorts of Government officials than Mr

Mr Bennett's paper on the telephoning of great cities referred mostly to the arrangement of details of exchange

mostry to the arrangement of details of exchange Prof. G Forber read a long paper, in which he gave an account of recent progress in the use of electric motors. It was of an interesting nature, and dealt largely with the advance that has been made in America. We trust Mr. Forbes is better acquainted with Transatiantic electrical practice than he is with one branch, at least, of British practice, for when he said, as we understood him, that there are no electrical cranes in England, he was certainly wide of the mark
Papers by Mr N Watts, on electric fire-damp indicators, as

by J. A Timmis, on electric lighting in trains, were also on the

On Tuesday, August 25, Section G held its last sitting, and there was a varied selection of papers. The first was a contribution by Mr. A R Bennett, in which he advocated a system of house-to-house parels distribution, which would certainly be very convenient if it could be carried out. He proposes tunnels under the street with injunture electric railways. That would be a difficult higher to firrange in any of our cities, the space being so occupied by gas and water-pipes, severa, electric

wires, hydraulic mains, and many other things, were the tunnels wires, nyurauin mains, and many other things, were the tunnels simply to be run straight away with only stations at distant points, but Mr Bennett proposes to make this a house-to-house service, each subscriber having his own siding. The tube would be rectangular, with two lines of rails one above the other. By means of semaphores at the central station, worked electrically by the passage of the train, so that the operator can always tell where the train is, and by further electrical connection he is able to shunt the train into the subscriber's own siding. one subscriber wants to send a parcel to another, he procures a truck, and despatches this through the tunnel to the central station, from whence the operator forwards it to the right address. There is even an arrangement for unloading automa-tically, and the truck can then be brought back by the operator without the intervention of the subscriber. The idea is fasci-

tically, and the truck can then be brought hand by the operation without the intervention of the shapener. The least is factive without the intervention of the shapener. The least is factive that the least of the of the screw-propeller was essentially non-scientific. He made his chief discovery in an endeavour to do one thing, but pro-duced the reverse result. When Griffith first used the spherical

duced the reverse result. When crimin nest used the spherical boss, he was trying to produce a retarding effect, but found, on trial, that he had added greatly to the efficiency of the screw. Mr Beaumont also read a paper on the screw-propeller He detenbed a method of reversing the direction of thrust by means of feath.rmg.rbidee, on the well-known Bevis principle. The advantages claimed were that, as the engines and screw would be always running in one direction, there would be no momentum of moving parts to be overcome when it was desired to go from of moving parts to be overcome when it was desired to go from ahead to astern, or vice verid, and therefore there would be less danger of breakage of the mechanism. The proposal was somewhat rogicily handled in the discussion which followed, but we think that Mr Beaumont fairly held his own in his reply. The most, valid objection appeared to be that of Mr Heard, who pomted out that the pressure on a given area of the blade was pointed out that the pressure on a great act of the by no means constant throughout each revolution, and the disturbance would cause the joints of the mechanism to wear. For this reason there would be introduced an undesirable and even dangerous play on the pins after the apparatus had been in use some time

A paper upon non-conducting coverings for steam-boilers having been read, the business of Section G was brought to a close with the usual votes of thanks.

ANTHROPOLOGY AT THE BRITISH ASSOCIATION.

THE proceedings began with the President's address, after which Prof. R. K. Douglas read a paper on the social and religious ideas of the Chinese as illustrated in the indeographic characters of the language. After a short introduction, showing that the Chinese designaphic characters are preture writings, the three transportations of the profession of the contract of the profession of the contract of the profession of the profession of the domestic life were illustrated by a number of ideographic dief where illustrated by a number of ideographic dief which will be a the profession of the contract of the profession of the contract of the profession of t

with marriage; and the evidences of pastoral as well as of agricultural habits among the people. The paper concluded with references to the counage of the country as described in the ideograms employed to represent its various forms.

ideograms employed to represent its various forms.

The following papers were also read on recent progress in
the analysis of vowel sounds, by Dr. R. J. Lloyd; family
life of the Haidas (Queen Charlotte Islands), by the Rev
Charles Harrison; and the Report of the North-Western Tribes of Canada Committee. This last is again the work of Dr Franz Boas in the interesting ethnological field of British Franz Boas in the interesting ethnological field of British Columbia II consists of two parts, the first being devoted to the Bilquila, a people inhabiting a limited tract in the vicinity of Dean Inlet and Bentinick Arms, the second dealing with the physical characteristics of the tribes of the North-west coast

physical control of the U.S. Bureau of himology Fepton fax Muller then made some remarks on the work of Mayor J. W. Powell, Director of the U.S. Bureau of himology He and that he had just received the proof-these of a most unsportant publication on the classification of the Indian language. spoken in America. It is a splendid piece of workmanship from Major Powell, the indefatigable Director of the American from Mayor Powell, the indefatigable Director of the American Bareas of Ethnology. The publications of that Bareas coast amongst the most valuable contributions to anthropological sceneos, and they reflect the highest credit, not only on Major Gordenset, which has swactioned a very large outlay for the prosecution of these studies. There was stim in the way these volumes are brought out, and most of the papers, contained in them surper the student with that confidence which can only be produced by honest, conscientious, and truly scholarities work. Our American frends have precreed that it is a motional duty to preserve as much as can still be preserved of the languages and thoughts of the industrial to preserve as much as can still be preserved of the languages and thoughts of the indigenous races who were the earliest dwellers on American soil. They know that the study of what Prof. Max Muller ventured to call intellectual geology a quite as important as that of terrestrial geology, and that the study of the lower strata contains the key to a right understanding of the higher strata in the growth of the human mind. Coming generic tions will call us to account for having allowed the old world to vanish without trying to preserve its records. People who ask what can be the use of preserving the language of the Mohawks forget what we would give if some scholar at the Mohawka forget what we would give if some echolar at the time of Cato or Casar hal winten down, what many could then easily have done, a grammar of the Ertuscan Inspanger of the Casar half with the case of the Casar half with English colonies Loid Granville saw that such an undertaking was a national duty, and that the necessary funds should be con tributed by the various colonies. What a magnificent work this would have been. But while the American Government has pushed forward its work, Lord Granville's scheme expired in the pigeon-holes of the Colonii Office. America may well be proud of Major Powell, who would not allow the treasures colonii. lected by various scholars and Government officials to moulder and perish. He is a true enthusisst, not a man of mere impulse and good intentions, but a man of sustained effort in his work He deserves the hearty thanks of the Association, and more

He deserves the heatty thanks of the Association, and more separally of the Anthropological Section.

The whole of Friday morning was occupied by a paper by the Marquess of Bute, on the language of Teneriffe. The difficulties in the study of the language are due to the fact that the abordinanal words have been collected from All the Islands without indicating their several origins, so that the Teneriffe words were not at first easily distinguished hitherto have held three opinions as to this language. The first

hitherto have held three opinions as to this language. The first is that of Dr. (List, who considered the language American (and the people African), the second, advanced by Sir Edmund that the third helds that the Tenefiffiam were of Aryan ongue. Dr. Edward B. Tylor read a paper on the limits of savage feiglion. It has alred become left by the inquiries of anthropologists that the world-famous Great Spirit of the North American Tolians arose from the teaching of the Jesuit mission-American immass arose from the teachings of the jesuit mission-aries in Canada early in the seventeenth century. This and analogous names for a Supreme Deity, unknown previously to native belief, have since spread over North America, amalga mating with native doctrines and ceremonial rites into highly

interesting but perplexing combinations. The mistaken attribu-tion to barbaric races of theological beliefs really belonging to the cultured world, as well as the development among races of new religious formations under cultured influence, are due to several causes, which it is the object of this paper to examine (1) direct adoption from foreign teachers. (2) the exaggeration of genuine native deities of a lower order into a exaggeration of genuine native deities of a lower order into a god or devil. (3) the conversion of native words, denoting a whole class of minor spiritual beings, such as ghosts or demons, into individual nanes, alleged to he those of a Supreme Good Detty or a rival Evil Detty

H. Ling Roth read a paper on convoide, in which he gave an account of the distribution of this curious custom, and showed

that the savage believes that there is some hidden link which binds the new-born child to its father, and he argued that the practice of contrade is to prevent the father hewitching his child. In a paper by Mr. S E Peal, on the moreng and other In a paper by Mr. S E Peal, on the morong and other customs of the natives of Asam, the author shows that this institution of the morone, or club-house for the unmarried, is very widely distributed over the whole of the Indo Pacific region, and he argues that it is, in fact, a relic of pre marriage communism Moreover, this quatom being so often found associated with others of a distinctly non-Aryan character, such as juming, lat-tooing, blackening the teeth, building on piles, head-hunting, &c, has led him to suspect former racial affinity, even among such widely different types as Papuan and Mongol. Diavidian and Sawatori

A paper by the Rev B Danks, on the aurual customs of New Britain, was read

In a paper on the worship of metcorites, Prof H. A. Newton, on Monday, gave a series of accounts of divine honours having been paid to meteoric stones in early times, and of myths and oeen paid to meteoric stones in early times, and or myths and traditions pointing to such worship. Particular attention was directed to the indications of such worship that are found in Greek and Roman history and literature

THURSDAY, OCTOBER 1, 1801.

THE BACTERIOLOGICAL EXAMINATION OF

Manuel Pratique d'Analyse Bactériologique des Eaux.
Par le Dr Miquel. (Paris. Gauthier-Villars et Fils, 1891.)

THERE is probably no body of scientific men amongst whom national feeling and prejudice are so little under control as the workers in the domain of bacterology. In perusing memoirs, text-books, dictionary-articles, and literature of every kind bearing upon this infant science, the reader must almost invariably take into consideration the language in which they are written, more especially whether German or French, and if the author belongs to nether of these rival nationalities, it is not unfrequently desirable to ascertain in which of the two camps he has been educated, for, unless this be made allowance for, a warped and often erroneous impression will be carried away.

The present work certainly forms no exception to this state of things; indeed, this phenomenon of party-spirit is regretably prominent. Thus, in reading one of the first paragraphs, beginning with "Les premières statistiques relatives à la richesse bactérisente des eaux furent publiées par moi," and, indeed, throughout these pages we are reminded of the words of the deeply lamented savount who commenced his monumental work with "La chimie est une science française," and perhaps even more of the famous utterance, "L'étai, c'est moi?"

Dr Miquel's treatise, consisting of 194 pages, is divided into five chapters, dealing respectively with (1) the collection of samples, (2) the transport of the collected water, (3) the quantitative analysis, (4) the qualitative analysis, (5) the interpretation of the results obtained. On these subjects Dr. Miquel should be well qualified to write, because, as be informs us, it is only in his laboratory at Montsouris that the bacteriological examination of water has been carried on over a period of eleven years. Indeed, we know of no bacteriologist who has so entirely devoted his attention to the subject of micro-organisms in air and water as Dr Miquel, whose name is so inseparably connected with "les organismes vivants de l'atmosphère." His energies have, however, apparently not been so successfully directed to the aquatic as to the aerial microbes, for we do not connect Dr Miquel's name with any of the more important advances that have been made in our knowledge of the bacteria in water during the past ten years. The comparative sterility of Dr Miquel's researches in this direction is perhaps partially to be accounted for through the extraordinarily cumbrous method of water-examination which he formerly exclusively employed, and which has placed him at a great disadvantage by the side of those investigators who at once availed themselves of Koch's methods, which Dr. Miquel, like many other French bacteriologists, has only adopted with reluctance, or almost under compulsion. The chief interest attaching to the bacteriological examination of water lies in its application to the hygiene of water-supply, inasmuch as it is all but certain that two at least of the most fatal zymotic diseases-cholera and

typhoid-can be, and are, constantly propagated through the presence of specific micro-organisms in water, and indeed the majority of bacteriologists are agreed as to the particular forms responsible for these diseases. On this account it is conceived by many that the primary object of the bacteriological examination should be the search for such pathogenic microbes. This view is apparently endorsed by Dr. Miquel when he says, "Le but que doit poursuivre le micrographe dans les analyses bactériologiques de l'eau est sans contredit la découverte des organismes pathogènes", although the logical conclusion to be drawn from the pages which follow, and in which he details the methods to be pursued in this quest, is that such an investigation is generally fraught with insuperable difficulties, and, for sanitary purposes, practically worthless Thus, without wishing to detract from the importance of the discovery by Chantemesse, Widal, and others of the typhoid bacillus in certain waters which had been suspected of propagating this disease amongst their consumers, it is surely obvious that, even if this organism could be detected with unerring certainty in any water in which it was present, a search for this bacillus in the ordinary course of water examination would still have only a very subsidiary interest. Waters are surely not only to be condemned for drinking-purposes when they contain the germs of zymotic disease at the time of analysis, but in all cases when they are subject to contaminations which may at any time contain such germs. Sewage-contaminated waters must on this account be invariably proscribed, quite irrespectively of whether the sewage is, at the time that the water is submitted to examination, derived from healthy or from diseased persons. In the present state of our knowledge there can be no doubt that chemical analysis affords us in general a better, although a far from perfect, indication of sewage contamination than do the results of bac-teriological examination. The real value of these bacteriological investigations, if judiciously applied, consists in their power of furnishing us with information as to the probable fate of dangerous organisms, should they gain access to drinking-water. It is by their means that we have learnt that many such organisms can preserve their vitality, nay, in some cases can actually undergo multiplication, in ordinary drinking-water, that they are destroyed by maintaining the water at the boiling-point for a short time; and that they are more or less perfectly removed by some processes of filtration and precipitation. whilst other processes of the same nature are worthless, or even worse

These Inapprant results are of the greater value manusch as they have been obtained not only by experimenting with the few pathogenic organisms with which we are at present acquainted, but by studying the effect of there several processes on the complex mixtures of micro-of-gramms is that are to be found in natural waters. The rapidity with which this knowledge has been acquired is due to the quantitative accuracy combined with facility of manipulation which characterize the method of gatinne-plate clitture. It has been repeatedly urged against this method that it is incapable of revealing many well-known forms of bacterns which either do not grow in the gelatine-pletone medium at all, or at any rate not at those temperatures at which it still remains solid, and it

514

is in this respect that Dr. Miguel claims superiority for his infinitely more laborious method of "ensemencements fractionnés " in bouillon It is obvious that labour must be no consideration if any great scientific advantage is to be attained, but, on the other hand, the unnecessary complication of processes, without corresponding benefits. must invariably lead to the retardation of scientific progress Now, it would certainly appear that the benefits obtained by Miguel's process are in no way commensurate with the additional labour which it entails. Thus, his process is also incapable of revealing all the microbes which may be present in water, and yields at best only a closer approximation to the total number than does the gelatine method. For the general purposes of the bacteriological examination of water, however, it is of very little consequence whether the method employed reveals, say, 30, 50, 70, or 50 per cent of the total number of microhes present, all that is required being a result which will serve for comparison. Thus, supposing it is desired to ascertain the efficiency of some process of filtration, provided that the unfiltered and filtered waters respectively are submitted to the same method of examination, the comparative result will be the same whether 50 per cent only or all the microbes present are in both cases enumerated. Thus putting this statement to the test of actual experiment, from the results of the gelatine-plate method of examination I reported to the Local Government Board in 1886 that the average reduction in the number of micro-organisms present in Thames water effected by the sand-filtration of the several London water companies amounted to-

```
98 6 per cent for the Chelsea Company,
                        West Middlesex Company.
                       Southwark Company,
Grand Iunction Company,
96 2
                       Lambeth Company,
```

whilst Dr Miquel in 1890 gives as the effect of sandfiltration on the water of the River Loire a reduction of 99 3 per cent. in one case, and 99 4 per cent in another case A concordance more complete than this can certainly not be demanded Similarly it can be shown that Dr Miquel's method of water examination has not yielded any results of importance which had not already been arrived at before by other investigators using the more expeditious method of plate cultivation. It is indeed only for such differential experiments as that referred to above that the bacteriological examination of water, in the present state of our knowledge, is really of much value, for any judgment as to the purity or otherwise of a sample of water based upon the actual number of microbes found in a given volume of it, is liable to lead to the most serious errors, in consequence of the remarkable power which some bacteria possess of multiplying to an extraordinary extent in waters of the greatest organic purity, in fact, it is precisely in the purest waters that such multiplication is often most pronounced. It is the possibility of such multiplication taking place which renders it imperative that samples of water should be submitted to bacteriological examination within a few hours of their collection In order to overcome this difficulty, which has hitherto debarred the examination of waters from distant sources, Dr Miquel has the samples transmitted in a box surrounded with ice; to this there are manifold objections,

for the low temperature thus secured by no means completely arrests the multiplication of some bacteria, whilst it causes the destruction of others. Dr George Frank, of Berlin, on the other hand, seeks to overcome the difficulty by deputing to persons on the spot the task not only of collecting the samples, but also of preparing the plate-cultures, but, considering the nature of the instructions which he finds it necessary to give to the novices to whom this work may fall, the expedient does not appear very promising The following is a verbatim extract from these instructions recently published in a German scientific journal of repute, which surely demands no comment :--

"The person commissioned with the collection of the sample takes off his coat, turns up his shirt-sleeves on both arms, fastening them so securely that they cannot fall down of themselves I hen he washes his hands and arms most carefully with soap and brush to above the elbow-joint Special care must be bestowed upon the cleansing of the finger-nails, which must if necessary be treated with the nail-file. Finally, the person in question dries himself with a clean towel."

We take it that the value of results depending upon manipulations carried out by persons requiring these instructions would be such that it would be no loss if they were dispensed with altogether Indeed, unless the bacteriological examination of water be invariably carried out by qualified persons, and by them employed only in cases where it is really capable of rendering service, it is certain to fall into that disrepute which has so frequently been drawn down upon the chemical examination of water through incompetent analysts. Indeed the bacteriological method has already seriously suffered in public estimation through the contradictions which have resulted from the attempts made in some quarters to classify waters according to the number of microbes revealed on cultivation. Such arbitrary standards have already done much mischief in the case of the chemical analysis of water, in the bacteriological examination they are still more reprehensible, and it is deeply to be regretted that Dr Miquel, in this most recent work on the subject, should seek to perpetuate a system of standards which experience shows to be quite untenable

The work concludes with some excellent recommendations as to the sterilization of water for drinking-purposes, a subject which cannot be too frequently brought into public notice, for, using Dr Miquel's own words, "la vie d'un homine a bien sa valeur à côté du prix insignifiant auquel revient le litre d'eau purgée de germes qu'il peut consommer en vingt-quatre heures "

PERCY F FRANKLAND

EPIDEMIC INFLUENZA

Epidemic Influenza · Notes on its Origin and Method of Spread By Richard Sisley, M.D (London: Longmans, Green, and Co., 1891)

THE object of this brief treatise, which was prepared before the issue of the Report of the Local Government Board, is to prove the doctrine, widely held by physicians of eminence in the eighteenth century, that influenza is contagious, or, more strictly speaking, infectious, and therefore, in the opinion of the author, fit to be included among the diseases of which notification is locally compulsory. The book is somewhat peculiar in its arrangement, but in the essential qualities of impartiality and clearness leaves nothing to be desired Many readers who do not require more than specimens of evidence, will thank Dr Sisley for compressing the digest of "many thousands" of notes into such narrow compass, but other minds will require a chain of which every link is massive, to guide them to the point of view whence practical conclusions are palpable. If the manner of statement is somewhat bare, and examples rather scanty, in the exposition of a strong but disputed case, the facts brought forward bear none the less value in their neutral setting, and go far to justify the proposition with which he confronts us at the outset, derived from a study of the distribution of the disease and from its pathological character Valuable assistance from Dr. Klein. Prof Fleming, and many others, has enabled him to include in his pages some interesting matter relating to the microbic nature of the epidemic and its relation to a similar disease in animals. After all that has been conjectured on the latter point, it appears that evidence of any unusual prevalence of influenza among animals at the time is still wanting

The original seat of influenta, which has been obscurely indicated in previous times as lying somewhere "in the East," has now been discerned in Mongolian and Chinese territory, for we have two independent accounts, each speaking of influents as not uncommon in some parts of China. In Mongolia "its seldom proves, fittal, but travellers are careful to avoid it, and no one would think of using the pot or ladle of a family suffering from this sickness". If the disease is sporadic and endemic in these countries, the population may be to some degree protected against epidemic outbreaks, for some degree protected against epidemic outbreaks, for much less marked in one to the indicate of the production one year, and least, on the whole, in those places where it was previously most severe.

The notes from Bokhara, translated in this volume, are of great importance, for they show how a wet spring had turned the neighbouring country into a perfect marsh, from which, when the hot weather set in, poisonous exhalations were given forth, and how the people, crowded together with horses, cattle, and sheep between high walls, distressed and weak with starvation and disease, were attacked much earlier than usual, in the first heat of summer, with malaria, and how this was quickly followed by an epidemic of influenza, reaching its height in July 1889. The extension of the disease westwards from Bokhara by the flight of convalescents to Russia, and eastwards by caravans to post-stations in Siberia, has been noticed in the official Report, and completes the evidence connecting the European epidemic with the miserable condition of an Asiatic town Upon such a soil, influenza sprang into fatal activity, and acquired, as we may fairly infer, a particular virulence In similar conditions, amid the filth, floods, and famines of Asiatic countries, cholera and other plagues of men and animals have been evolved and have set forth on their destructive march

By reports from several medical officers, and by a number of charts showing the curve of prevalence of the

disease in English and foreign cities, Dr Sisley shows that we have no experience of any sudden prostration of a large population within a few days, such as was formerly supposed to occur, but that the rise is always gradual from a few cases to hundreds and thousands, the maximum usually occurring from one to two months after the first cases in the locality have been noted. Last century Dr Havgarth had been fortunate in discovering the person who brought the infection to each place in his district. If equal pains had been taken in 1800, when the disease was on its way to us from Russia, the persons who conveyed it from country to country might, no doubt, have been identified. The author has not been able to find a single instance in which there was a sudden infection of a large number of people without the previous existence of cases of the disease, and wherever its course was studied with care, it was seen to spread in the same way as other infectious diseases "atmospheric" doctrine, though previously disproved with regard to rabies, cholera, and pestilence in general, still finds a stronghold in consumption and influenza.

The classic examples of ships supposed to have been attacked on the ocean by wind-borne influence, as well as those of towns supposed to have been pro-trated "in a single day," really bear testimony to the insidious growth of the disease and to the necessity of early recognition. Neither in this volume nor in others on the sample day the disease and to the necessity of early recognition. Neither in this volume nor in others on the supposition of the same of the growth of the growth of the day of the d

The total evemption of lighthouse-keepers, deep-sea shehreme, and univisited shands, is scarcely noticed by Dr visley, but he considers the rarity of influenta among prisoners to have been due to their removal from sources of contagion, and relates a very interesting case of contagion, and relates a very interesting case of contagion, and relates a very interesting case of experient infection of a man on his way home from a light-ship through contact with the crew of a fishing-boat, said to be in good health

Dr Sisley concludes that there is no convincing proof of transmission through unaffected persons, letters, &c : but a series of cases each of considerable weight surely amounts to evidence strong enough to justify some precautions, such as would be taken with the organic dust from more serious diseases, eg scarlet fever and diphtheria, which are so transmissible is happily a great deal in common in the mode of spread of most symotic diseases, and disinfection as usually practised could hardly be misapplied to influenza The same may be said with regard to isolation, for no attack, however trivial in itself, is a maiter of indifference to the public, if it may result in widespread illness, loss of work, and distress. A short retirement is desirable in the interest both of the patient and of the public But Dr Sisley can hardly desire that notification should take place on exactly the same lines as that of other diseases, for local authorities would with reason wince at the expense, and unless the notification were a national undertaking, no district would be adequately protected thereby from imported cases. Complete and national measures of notification and isolation, with the co-operation of local authorities, would be much more likely to be effectual. An expenditure of one-fiftieth of the cost of the recent epidemic would probably secure the country from any such infliction in future. But we must admit that without a somewhat strict supervision at ports of entry during the period of prevalence in other countries, and without provision for the segregation of slight or suspected cases during that period, mere notification would not be likely to put a stop to the spread of influenza The early cases are worth taking a great deal of trouble to discover and isolate When once many cases have occurred in a locality, the further progress of so protean a disease is difficult to The best chance of averting an epidemic must be sought in scrupulous care for early isolation, in tracing the movements of travellers from infected towns. and in the increased practice of ventilation in private houses and in public gatherings Like typhus, influenza seems incapable of inflicting much damage except through the medium of close, confined, and impure air, and where measures of isolation and disinfection are used it seldom spreads. But the infectious character of influenza must be internationally recognized before protective regulations can achieve a full measure of success, R RUSSELL

GENERAL CHEMICAL MINERALOGY.

Allgemeine Chemische Mineralogie Von Dr. C. Doelter, O. Professor der Mineralogie an der K K Universität Graz. With 14 Figures in the Text (Leiping: W. Engelmann, 1890)

M INERALOGY, at first purely descriptive, has been raised to the dignity of an experimental scence by the application of the principles of chemistry and physics. The writer of a mineralogical text-book is thus met at the outset with the difficulty of deciding what amount of knowledge of chemistry and physics to assume in his reader. With regard to the chemical sole assume in his reader with regard to the chemical sole assume that he knows verified, and yet, somewhat inconsistently, to make the exposition of the atomic theory and the fundamental principles of chemistry so brief as to be of little service to one who has had no previous acquaintance with the subject

The author of the present, in many respects useful and suggestive, book follows the same lines. The whole account of the findiamental chemical theories occupies about ten pages of the introduction. The same fault will be found in other parts of the book. e.g. it would be difficult to say to what class of reader a large portion of the chapter on chemical analysis would be useful. In his endeavour to introduce as many extracts as possible from the current literature of the subject, the author allows himself in many places to become somewhat selectly. In spite of this, the book, with its wealth of information upon points which have not hitherto found a place in ordinary mineralogical text-books, will be found to give a very good idea of the present state of mineralogical selectnost, will be found to give a very good idea of the present state of mineralogical selectnost or view.

The arrangement of the book is in seven sections, viz (1) introduction; (2) chemical crystallography; (3) chemical analysis of minerals; (4) synthesis of minerals; (5) metamorphism of minerals; (6) formation of minerals

NO. 1144, VOL. 44]

in nature; (7) chemical composition and constitution of minerals

In the introduction, containing an account of the atomic theory and its consequences, one or two suggestive ideas will be found . e.g. the correspondence, pointed out by Tschermak, between the chemical law of multiple proportions and the crystallographic law of simple parameter ratios: and also the analogy between the law of constant proportion by weight and the fundamental crystallographic law of constancy of angle. The subject of chemical crystallography receives very full treatment, Here the reader is initiated into the mysteries of chemical and physical isomerism, polymorphism, enantiotropy, isomorphism, isodimorphism, isogonism, morphotropy, &c : and if the perusal of this section, as well as of the last, on the constitution of minerals, shall leave him with a rather confused and unfavourable idea of the subject, the fault should perhaps he rather attributed to the present imperfect state of our knowledge than to the author At present it is in most cases impossible to say whether bodies are polymeric, metameric, or chemical isomers

As regards isomorphism, if the formation of mixed crystals is to remain the test, the original definition of Mitscherlich must be modified to suit the fact of the formation of mixed crystals from compounds of not precisely analogous chemical composition. Thus, according to modern views, isomorphism is in some degree to be deposed from its proud position as an infallible guide to chemical composition. The insidious nature of the attack upon this ancient stronghold of the faith may be judged by a comparison of one of the latest definitions of isomorphism with the original definition of Mitscherlich. According to the latter, isomorphism is the power which two or more compounds of analogous chemical composition possess of crystallizing in the same or similar crystalline forms, and of mixing in varying proportions to form homogeneous crystals. The latest definition is that bodies are isomorphous which, with for the most part similar chemical composition, possess the property of crystallizing in similar crystalline forms, and of forming mixed crystals which morphologically and physically graduate into each other. Such a change it is expected would lead to a considerable simplification in many of the formulæ which have been made unnecessarily complicated in order to comply with the requirements of Mitscherlich's definition

The section on chemical analysis of minerals is one of the least statisfactory in the book. Short summaries of analytical methods can be of little service to any class of reader. Amongst matter which will not be generally found in the ordinary chemical test-book, this section contains some account of microchemical reactions, of the methods for the mechanical separation of minerals, so as on the contract of the course of analysis and directions for the course of analysis to be pursued in the case of the more important minerals.

The important subject of mineral synthesis receives more complete treatment than any other in the book. The section contains general accounts of the various methods for the artificial production of minerals by chemical reactions, fusion, sublimation, electrolysis, diffusion, &c., with detailed descriptions of the apparatus required.

The sections on the metamorphism of minerals, and on the formation of minerals in nature, will be found of great interest to the petrologist. Here are described the effects on minerals of heat, of gases at high temperatures, of fusion, of fused maginas, of water containing carbonic acid. &c. In the last section, dealing with the composition and constitution of minerals, the present imperfect state of our knowledge is brought prominently to light The battle is still being fought between the so-called chemical, liquid, and crystal molecule; between constitutional and empirical formulæ Mineralogists are beginning to understand that it is impracticable to attempt to use for complicated minerals principles which are only applicable to volatile organic compounds, and the idea is gaining ground that many minerals are molecular compounds only capable of existing in the solid state, the crystal molecule being built up of different chemical molecules

The author intends to supplement the present work by another, entitled "Chemical Mineralogy," in which the composition, synthesis, &c, of each individual mineral will be treated more particularly. The present volume is intended as quite a general treatuse on the subject of mineral chemistry, in fact, we cannot help thinking that in many parts the treatment is far too general, and that the book has been partially sacrificed for the sake of the volume that is to follow. The value of the book is increased by the lists of references to the literature which precede each section.

OUR BOOK SHELF.

Bush Friends in Tasmania: Native Flowers, Frints, and Insectit, drawn from Nature, with Prose Descriptions and Illustrations in Verse By Louisa A Merchith Executed by Vinent Brooks, Day, and Son. (London and New York Macmillan and Co., 1891)

UPWARDS of thirty years ago Mrs Meredith gave the world a volume containing admirable coloured figures of world a volume containing adminable coolered lightes and a selection from the many beautiful plants and insects that inhabit her island home, Tasmania, and now, in the evening of a long life, she has travelled to the old country to publish a second volume, which is to be the last Her purpose achieved, she "hopes to return and end her days among her children in that pleasant colony," which has given a brighter home to so many of our kith and kin Lovers of the beauties of Nature in this country will find much pleasure and instruction in this second volume from that talented lady's pen and pencil, and will be able thereby to form some conception of the totally different kind of vegetation from our own that clothes this remote southern island, as well as the great Australian country, for it is only a part of the same flora. To the colonists themselves the book will be even more attractive, as a means of becoming acquainted with the names and affinities of the beautiful objects with which they are surrounded. It will also, it is to be hoped, teach them to prize and preserve these rare and precious gifts Like all true lovers of Nature, Mrs Meredith deplores the wanton destruction of rare flowers near Hobart by thoughtless or greedy persons whose only aim seems to be quantity.

The botanical part of Mrs. Meredith's book is per-

The botanical part of Mrs. Meredith's book is perfectly trustworthy, having been scrutinized by so eminent an authority as Sir Joseph Hooker; and Prof. Westwood furnished the names of the insects.

Some of the poems have a special interest in connection with the early history of the settlement of Tasmania

Notably an "Old Story" of 1834, which narrates the massacre by aborigines of a whole family—father, mother, and seven children.

The Elementary Geometry of Conics, with a Chapter on the Line Infinity Bs C Taylor, D D. (Cambridge Deighton, Bell, and Co., 1891)

DR TAYLOR'S "Geometry of Contas" is so well known, and has met with such acceptance—this is the seventh edition, revised—that we are not called upon to give a bref notice. A new chapter ((u)) contains "a course for the contains a part of the contains a course for the contains a part of the contains a course for the contains a part of the cont

order to draw the asymptotes before tracing the curve, for the hyperbola seems to have been discovered from its "equation" (A I G T Report, 1800, p. 12). It is somewhat remarkable that Dr Taylor does not give a proof of this equation. We append one. Taking his figure on p. 103, we draw the second adymptote Now draw PM parallel to C/p, cutting the axis in K, and the second asymptote in M then.

4CM MP = 4MK . MP = (MP + MK)² - (MP - MK)³
=
$$C\rho^2 - KP^2 + \lambda^2(\rho N^2 - PN^2)$$
 (where λ is a constant)
= $\lambda^2(S\rho^2 - SP^2)$
= $\lambda^2(S\rho^2 - \rho^2) = \lambda^2 - SY^2 - C\alpha^2 + \alpha^2 + \delta^2$

Again, let PQ be any chord meeting the asymptotes in p, q, and let Ql, Pm, parallel to Cp, Cq respectively, meet those lines in l. m. Then we have

$$\frac{Pq}{Cm} = \frac{Pp}{pm} = \frac{pq}{Cp} = \frac{Qq}{Ql},$$

$$\frac{Pq}{Qq} - \frac{Cm}{Ql} = \frac{Cl}{Pm} = \frac{pQ}{Pp},$$

hence Qq

$$Qq = Qa$$
, and $Pa = \phi Q$.

Other properties occur to us, but the above are classic properties of the curve, and the wonder is that Dr. Taylor has not applied his new treatment to obtain them. There is no suggestion that they can be so obtained, either in the book or the original paper as printed in the A I G.T. Report.

Les Engrais Chimiques Par Georges Ville. Septième Édition. (Paris: M. Engel, 1890.)

THIS is a new edition of the author's lectures on chemical manures, which were first published in 1868, and which have been translated into seven languages. An English edition, by Mr. Crookes, was published in 1879. The sixth French edition has been out of print for about ten years, and during that time the price of chemical manures has considerably declined, on an average about 40 per control of the control

crops Thus, potassium chloride replaces potassium nitrate in the manure for leguminous plants, and in some cases a mixture of potassium chloride and ammonium sulphate replaces potassium nitrate, and a few other alterations are suggested in the treatment of various crops Thomas's basic cinder is not mentioned as a source of phosphoric acid The lectures themselves, and some controversial matter, are reprinted in their original form, and but little new matter is added

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Nisther can he undertake to return, or to correspond with the worters of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications!

The Bird-Collections in the Oxford University Museum

DURING a recent visit to Oxford I took the opportunity of examining the collection of birds in the University Museum, and her leave to offer a few remarks upon its condition

First, as regards the mounted specimens, there are three series belonging to this category -
(1) The general series in the Central Court. This numbers

(1) The general series in the Central Court. This numbers about 1100 speedment, which are contained in twelve cases, placed in opposite rows of six each, but rather mixed up with a ranged according to Cap's etc., but rather mixed up with containing to a content of the containing to the containing to a containing to a containing to a containing the containing th The whole series requires renovation and rearrangement, ac-cording to some modern system, and the orders and families should be designated by labels, and distinctly separated one from another

from another

(2) The collection of Arctic birds formed by Mr. J. Barrow, F.R.S, and presented to the Museum by that gentleman. This meresting collection, which has been well described by Mr. Harting in the /Mr., is placed in the gallery. It is well because the properties of the described to keep it apart from the general series.

(3) The Brutak series, also placed in the gallery, which is in fair order, shlooph it also requires revision and rearrangement according to some modern system. It ought not to be difficult to find some member of the Britah Dentihologists. Union to

undertake this task, provided that the authorities will allow him

Besides the mounted specimens, there are, as I understand, about 4000 skins of birds, most of which are "put away" in boxes in various parts of the building. Of these, the only portion boxes in various parts of the faulding. Of these, the only portion that I was able to see was the Bornean collection formed by Mr. Everett, and pastly described by Dr. Bowdler Sharpe in the Zoological Society's Proceedings. These are placed in some drawers in the main hall. The other skins are stated to be "Doced up," and are kept patily in a room on the ground floor, and parily in some "upper chamber," to which no ready access is possible.

I venture to suggest that one of the side rooms in the Museum should be cleared of its contents, and devoted entirely to the bird skins, and that they should be arranged there in calinets, so as to be accessible to the ormithologist. It is hardly right for a great and rich University to accept collections from persons who, in the words of the late Prince Bonaparte put forward on a similar occasion, "croyant qu'ils travaillaient pour la science, non pas travaillés que pour les mites "I may add that any assistance that I can give in carrying out this reform will be most gladly rendered P L SCIAFER 3 Hanover Square, London, W., September 4

Variation and Natural Selection

In Prof C Lloyd Morgan's Presidential address to the Bristol Naturalists' Society, on "The Nature and Origin of Variations" (of which he has kindly sent me a reprint from the Society's Proceedings), there are one or two points on which there seems to me to be a slight misconception; and as the difficulties auggested have probably occurred to other naturalists.

NO. 1144, VOL. 44

wish to make a few observations in the hope of throwing a

I wish to make a two observations in the more common little light on this observations that the plan of the variability of species in a state of nature which I have adduced in my "Darwinsin" (to which proofs Prof. ILoyd Morgan has made some important additions in his recent work on "Animal Life and Intelligence") he remarks: "We have been api to suppose that a species is so nicely adjusted to its surrounding conditions that all variations from the type, unless of a very insignificant character, would be rapidly and inevitably weeded out. This, it is clear, is not true at any rate for some species." And a little further on, after discussing the question whether variations in all directions occur in equal proportions-an equality which does not appear to me to be at all necessary, or to have been ever suggested as occurring that the evidence in Mr Wallace's third chapter, while con clusive as to the occurrence of variations, gives on analysis little or no evidence of any selective agency at work "

The difficulties here stated appear to me to depend, chiefly, on not taking account of some important facts in nature fact is, that the struggle for existence is intermittent in character. and only reaches a maximum at considerable intervals, which may be measured by tens of years or by centuries. The average number of the individuals of any species which reach maturity may be able to survive for some years in ordinary seasons or under ordinary attacks of enemies, but when exceptional periods of cold or drought or wet occur, with a corresponding scarcity of cold or drought or wet occur, with a conception, and certain kinds of food, or greater persecution from certain enemies, then a rigid selection comes into play, and all those individuals which vary too far from the mean standard of efficiency are destroyed

Another important consideration is that these epochs of severe struggle will not be all of a like nature, and thus only one parstudge, with not be all of a like fractic, and inde only one par-ticular kind of unbalanced or injurious variation may be eliminated by each of their. Hence it may be that for consider-able periods a most all the individuals that reach maturity may he able to survive, even though they exhibit large variations in many directions from the central type of the species. During such many directions from the central type of the sponce. During such quescent periods, the chief elimination will be among the young and immature. Thus, with birds probably mine tenths of the destruction occurs among the eggs and half fledged young, or among those which have just escaped from parental care, while those which have surved to breeding age only suffer a slight destruction in ordinary years, and this may occur partly among the less experienced, partly auong those which are old and somewhat feeble

somewhat feeble. The severe elimination that occurs in the earlier stages may be thought to be accidental, but I doubt if it is really so except in a very finall degree. The protections and concealment of the eags and young in the nest will depend chiefly on the mental qualities or invinits of the parents, and these will have been qualities or invinits of the parents, and these will have been dependent of the parents and the parents and the parents and the parents are the parents of the parents and the parents are the parents of the parents and the parents are the parents and the parents are the parents and the parents are the parents are the parents and the parents are the par deficiency And with young birds of the first year there will be an equally rigid selection of the incautious, and of those who are deficient in any of the sense-perceptions, or are less strong and active than their fellows.

The proof that there is a selective agency at work is, I think, to be found in the general stability of species during the period to be found in the general stability of species during the period of human observation, notwithstanding the large amount of variability that has been proved to exist. If there were no selection constantly going on, why should it happen that the kind of variations that occur so frequently under domestication. never maintain themselves in a state of nature? Examples of this class are white blackbirds or pigeons, black sheep, and unsymmetrically marked animals generally. These occur not unfrequently, as well as such sports as six-toed or stump-tailed cats, and they all persist and even increase under domestication,

cats, and they all persust and even nucrease under domentication, but never in a state of nature, and these seems no reason for the strength of the strength o tunate objection, since, in constantly recurring circumstances during the life of a savage, this very character must be of vital importance. Whether on the war-path, or in pursuit of game,

or when escaping from a human enemy or from a dangerous animal, the thickness of the sole, its insensibility to pain, and its resistance to wear and tear must have often determined life or death. A man who became sore footed after a long day's or desth. A man who became sore footed after a long day's tramp, or one whose thin tole was easily cut or torn by stones or stumps, could never compete with his thicker soled companions, other things being equal, and it seems to me that it would be difficult to choose a angle physical character whose variations would be more clearly subject to the law of selection. With the greater portion of Prof. Lloyd Morgan's very interesting address I am in perfect accord, and it is because his remarks and suggestions are usually so acute and so well founded

that I have thought it advisable to point out where I think that his objections have a less stable foundation ALFRED R WALLACE

A Rare Phenomenon,

THE rare phenomenon to which your two correspondents refer in their letters in your last issue (p 494) was visible here at pre-cisely the same time, and, viewed from Nottingham Forest, it presented a most interesting sight. It is currons that, as both presented a most interesting sight. It is carnots that, as both the time and duration of the phenomenon connection with its three times and duration of the phenomenon connection with its half more than the present of the present of the phenomenon of a well-defined display of the half more its expression of the phenomenon of a well-defined display of the half more its present of the phenomenon of the pheno character described by your correspondents, but vertical changing rays, several of which were distinctly orange-tinted
Nottingham, September 26.

Instruments in Just Intonation

As you have raised once more the question of justly in-toned instruments, may I ofter the following remarks? It does not seem likely that any arrangement for the organ would be practically adopted unless it permits as much freedom of modu-lation and of execution as that of equal temperament. To lation and of execution as that of equal temperament. To permit perfectly free modulation, with practically perfect intervals, nothing short of the cycle of fity-three will suffice. Now to construct a key-board with fifty three noises to the octave which can be played upon with the facility of a twelve note key-board and the facility of a twelve note key-board. seems impossible But the problem may be approached differently; as it is only necessary to use twelve notes at a time, the keyently; as its only necessary to me twelve notes at a time, the key-board might remain as it it, and rolly a mechanical deviewe would be required to make these twelve keys correspond to the required twice out of high necessary on large organity the mechanical difficulties could easily be overcome. For example, arrange a "duodenarum," and connected electrically to the fifty the trackers; 17. as suggested by Dr., Blitts-as a "duodenarum," and connected electrically to the fifty the trackers; 17. as when trackers would be a support of the connected to the trackers and the support of the connected studs -Bbb, Cbbb, Ast stude to tracker 46 for instance.

NO. 1144, VOL. 44

Opposite these studs would be another set of 117 connected to the twelve keys, e.c. C, B. B. Bat, D250, &c, all to the key C. between the two sets of stalls would be a frame carrying twelve contact pieces, the frame would then be moved along guides by the assistant, so that the twelve keys were electrically connected to the right doudgne of study, and hence could be made to open

the right group of pipe.

Thus the only alteration in printing required would be to mark the duodene on the music. All the extra complication would be thrown on the mechanical arrangements, and the It seems to on anist would be left in the same position as now me that any more complicated key-board would fail in a large organ, through overburdening the organist.

ROBI A LEITFELDT Firth College, Sheffield, September 14

Unusual Frost Phenomenon

"As perhaps you may never have seen this form of ground frost, I append a rough sketch of its very singular appearance

I have only shown three layers , there were five, but this may give you some klea of its appearance—quite a columnar hasaltic

appearance Every morning here after a sharp frost, the whole of the ground, where not covered by grass or rubbish, is raised up thus. On the sides of the cuttings and banks of our claim, these tee fibres may be seen projecting from the walls in bunches of snowy filaments, like spun glass. The sun, however, soon causes them to drop off, and they lie in heaps of some six inches in depth."

The Soaring of Birds

I HAVE read with much interest Mr Peal's account of the soaring of vultures, pelicans, adjutants, &c., over the plain of Upper Assam (NATURE, May 21, p.56). Their manner of flight is identical with that of caguills and harriers over the Canterbury Plains in New Zealand, which is about 150 miles long and 45 wide in its widest part. These birds begin to soar at a height of about 200 feet, and rise in slanting spirals to 2000 feet and under. The gulls are much the most numerous, and flocks of under. Ine guils are much the most numerous, and nocks of them may be seen soaring nearly every fine day in suinmer. Sometimes a number assemble, and after going round in circles for a short time, without rising, or rising very little, they come down, the condition of the air being apparently unfavourable for soaring. Whenever I have seen a flock finish an ascent, they all down, the community of the community of

limit of their ascent even for a short time, but reparated, sailing away downward to great distances

The explanation of soaring given by Mr Peal can hardly be true one. Bishop Courtenay has shown its inadequacy by proving that a bird in a uniform horizontal current is in no expect more able to support himself itlain an ealm. Though

proving that a time, in someon necroscial current is a my proving that a property is a support of the control o

without any relative motion of the parts, or so lulfe that it could be of no use in sourcing.

**Interpolation of the parts, the word is a right of the albarons [Narrus, and the parts of the parts of

is at its maximum, to the greatest advantage possible. It seems, therefore, that soaring at great heights cannot be explained on the same principle as the saining flight of the albatross, whose movements are confined to a comparatively than atratum of an exit the sae, in which the velocity of the wide increases rapidly extended to a comparative of the contractive of the c

with the height In Lyttelon Harbour, N.Z., which is surrounded by hills except at the entirance, the guill sear by using the upward current on the slopes, running in spirals in precasely the same motive power in the former kind of high it serident, and perhaps throws high on that of the latter. Standing on a slope of about 20, and about 100 feet above the see, I awa is faced of guills began to ascend over the slope. Being constantly among the happing they are very time, and several cane within 15 feet about 100 feet above the several cane within 15 feet about 100 feet above the several cane within 15 feet about 100 feet above the several cane within 15 feet about 100 feet about 100 feet above the contrast of the several cane within 15 feet about 100 feet about 1 In Lyttelton Harbour, N.Z., which is surrounded by hills of birds over a slope by means of the current flowing up it, and their descent in long inclines at a small angle with the horizontal, show that rapid motion through the air cause a great resistance in opposition to gravitation, which resistance has not yet, I believe, been accounted for quantitatively on mechanical prin-

upwand currents may be caused in two ways, but it would not be possible to gree a direct proof that the currents no analog are strong enough. If, however, birds are seen to sear when one or they are true causes of searing.

Leveryone who has watched the working of a windmail must make the search of the search

same time. This tendency of the lower strata to burst up in separate spots may exait where the instability is much less than that required to cause a tornado, as in the case of a plan strongly heated by the sun, and in the absence of any gyratory motion round the centre of an ascending current, there would be no whirlwand, only a

quiet ascent of air, in a slanting direction if there were any wind. Such ascending currents may be of small area, not much larger than the circles described by birds when soating. It seems possible that the object of describing circles may be to keep within the ascending current, though it is true they somekeep within the ascending current, though it is true they some-times describe circles when the ascending current is up a slope and not limited to a small area. If a plain much heated by the sun border on the sea, ascending currents will soon start a sea-breeze, and the cold air from the sea will soon restore the seability of the atmosphere In summer the sea breeze blows over the Canterbury Plains four or five days a week, beginning between 8 a m and noon. When delayed till near noon, the soil and lower strata of air are much heated, and as the previous nights are cool, the conditions for causing the unstable state are present I long ago remarked that the best time to look out for soaning birds is at the commencement of the year-breeze when it soaring birds is at the commencement of the var-preced when it is late. Soaring is much oftener seen here in summer than in winter, and is, I believe, more common, and the species of soaring birds more numerous, and the birds larger, in hot than in cold climates—that is, in climates where the unstable state of

the atmosphere is oftenest caused by the sun's heat.

Mr. Peal says "That there are no uprushes of air I have fairly good proof in the small tufts of cotton from the Bombyx fairly good proof in the small taffs of cotion from the Biemby-maldsbracom which cross the field of mytelescope whose examinate the Newgy lith at a ten, wenty, or there mides places as the same taken to be supported by the same taken to be supported by the same taken to be supported by the same to the same taken to be supported by the same to show that angle with the horizontal, and of convoletable sare, might be detected by a careful observer from the movements of small deducted by a careful observer from the movements of small are might to the same taken to the same taken to the same taken to the same taken to be supported by the same taken to the same taken to be supported by the same taken taken to be supported by the same taken to be supported by the same taken to be supported by the same taken taken to be supported by the same taken ta

easily escape observation. It is obvious that upward currents over a plain, caused either by variations in the velocity of the wind or by the unstations between the almost inscribble near the state of the stationshere, must be almost inscribble near the state of th

a stope.

I have often observed gulls with extended motionless wings following a steamer in the same relative position for several minutes. In every case it was clear that they used the current diverted upwards by the hull. Before the upward energy of this current is exhausted, a fast steamer has gone a good many tals current is exhausted, a last steamer has gone a good many yards, so that a bird is supported at some distance satern. Also an upward current of considerable strength would flow off the mizen sail of a ship s ailing near the wind and leaning over Christchurch, N.Z. A C Baints

Rain-making in Florids in the Fifties

THE article on "Rain-making in Texas" (NATURE, p. 473) recalled to my memory a passage of Dr. Th. Reye's book ("Wirbelstume, Tornados, &c.," Hanover, 1872, in which (at p. 12 and following) the author in question translates quotations from J. P. Espy's "Second and Third Report on Meteorology, 1851, auf Belchi des Senates der Union gedrukt" Meteorology, 1931, and necessity are seed that great and all experts 1857. The facts related were observed by the surveying officers George and Alexander Mackay. They (in Florida) had at their disposal great quantities of rushes (saw grass), which they set in flame, and the huge conflagrations were invariably followed by rain September 22.

A Dog Story

This following dog story may interest your rederation of the trial took morning. I are more rederadate the trial took morning at the most morning at the control of the

NO. 1144. VOL. 44

SOME NOTES ON THE FRANKFORT INTERNATIONAL FLECTRICAL EXHIBITION 1

A Page of Modern History

E LECTRIC transmission of power to great distances bids fair in the near future to change the whole commerce of the world, and yet the history of its developcommerce of the world, and yet the history of its develop-ment is all comprised within the last fourteen years. In a long paper read in the early part of 1877 before the Institution of Civil Engineers, "On the Transmission of Power to a Distance," the author, Prof. Henry Robinson (now the engineer to various electrical companies), does not even suggest the possibility of employing electricity for this purpose So that in the discussion Sir William Siemens remarked, "He might also refer to another method of transmitting power to a distance, which did not seem to have occurred to the author, perhaps because

it was of recent date, vir by electric conductors"

A week later, Sir W Siemens, in his Presidential address to the Iron and Steel Institute, throws out the idea of utilizing the power wasted in the Falls of Niagara, and after referring to the use of high-piessure water mains and quick-working steel ropes for transmitting power over one or two miles, he says, "Time will probably reveal to us effectual means of carrying power to great distances, but I cannot refrain from alluding to one which is, in my opinion, worthy of consideration namely, the electrical conductor" And he adds. " copper rod three inches in diameter would be capable of transmitting 1000 horse-power at a distance of, say, thirty miles

I he use of the electric current for the transmission of power over considerable distances was, therefore, fully present in the mind of Sir William Siemens in 1877, but not apparently the employment of the high potential differences which are absolutely necessary to make such a transmission commercially possible For a copper rod of three inches diameter, such as he speaks of, has a cross-section of nearly seven square inches, and could carry some 5000 or 6000 amperes without undue heating Therefore, even when the problem of transmitting 1000 horse-power over thirty miles was in question, he did not contemplate, apparently, using a pressure of more than about 100 volts.

At the commencement of the following year, 1878, in his Presidential address to the Society of Telegraph Engineers, he refers to his previous statement, and adds, Engineers, he refers to his previous statement, and adds, "Experiments have since been made with a view to ascertain the percentage of power that may be utilized at a distance." The result obtained, he says, is that "over apper cent of power expended at the distant place may oper cent of power expended at the distant place may oper cent of some control of the control of the oper cent loss, "This made, in reference to the oper cent loss, "This made, in reference to the oper cent loss, "This transmitted were of great though which the power was transmitted were of great through which the power were transmitted were of great

The length of the conductor employed in the above experiment is not given, but its approximate length, as well as what is understood by "great length," may be gathered from the context; for Sir William goes on to consider the problem "of distributing the power of a steam-engine of, say, 100 horse-power to twenty stations within a circle of a mile diameter", and although the distance to which it is proposed to transmit the power is only one mile, he assumes that the loss is what was found in the above experiment, viz. 60 per cent He further adds, "The size of the conductor necessary to convey the effect produced at each station need not exceed half an inch in external diameter." Clearly, then, as the power proposed to be diameter" Clearly, then, as the power proposed to be transmitted by the half-inch conductor to each station one mile distant was only 5 horse, there was no idea of using

' Continued from p 407

a potential difference in the transmission higher than that maintained between the terminals of a lamp

Two wrong notions misled people in those days-the one, that the maximum efficiency of a perfect electromotor could be only 50 per cent ; the other, quoting the remarks could be only 50 per cent; the other, quoting the remand of 51r W Siemens in the discussion of the paper read by Messrs. Higgs and Brittle at the Institution of Civil Legimenes somewhat later in the same year 1878, "In order to get the best effect out of a dynamo-electric machine there should be an external resistance not exceeding the resistance of the wire in the machine Hitherto it had been found not economical to increase the resistance in the machine to more than one ohm ; otherwise there was a loss of current through the heating of the coil If, therefore, there was a machine with one ohm resistance, there ought to be a conductor transmitting the power either to the light or the electro-magnetic engine not exceeding one ohm. He then goes magnetic engine not exceeding one ohm." He then goes on to consider that as the conductor is lengthened its cross-section must be increased in proportion to keep the resistance constant at one ohm, and he arrives at a result quite new at the time, viz that if the number of dynamos in parallel were increased in proportion to the length and cross-section of the line. "it was no dearer to transmit electromotive force to the greater than to the smaller distance.

romotive force to the greater than to the smaller distance."

Sir William Thomson grasps at once the novelty and importance of this idea, and renders it even more important by proposing to put all the dynamos in series at one end of the line, and all the lamps in series at the other. But it would still appear that even 40 per cent efficiency for transmission over a considerable distance could only be attained when "there were a sufficient number of be attained when "there were a sunctent number of lamps" to make it necessary to use many dynamos in parallel in accordance with blemens's proposal, or, many dynamos in series in accordance with Thomson's modification of Stemens's proposal.

In 1879, the electric transmission of power was still such a terra incognita that the largest firm of electrical

engineers in Europe could not be induced to tender for transmitting power over ten miles in India

At the British Association lecture in the autumn of 1879, Prof. Ayrton exposed the fallacy of assuming that 50 per cent was the maximum efficiency theoretically obtainable with an electromotor. He further proposed that, instead of employing many dynamos at one end of the line and many lamps at the other, there should be used a single dynamo and a single motor, with much wire on each, that the high potential of the line necessary for economical transmission of power should be maintained by running both dynamo and motor much faster than hitherto, and that both dynamo and motor should be separately excited Although not wholly free from the prevailing idea of that day—that electric transmission of power overlong distances would only be commercially possible when a very large amount of power had to be transmitted—he says, after discussing the subject, "So now we may conclude that the most efficient way to transfer energy electrically is to use a generator producing a high electromotive force and a motor producing a return high electromotive force, and by so doing the waste of power in the transmission ought, consider, to be able to be diminished with our best existing dynamo-electric machines to about 30 per cent."
This was perhaps the first time that it had been even

suggested that the efficiency in electric transmission of

power could be more than 50 per cent.

Further, the lecturer proposed to use in all cases this high E M F. motor, whether the received power were required for motive purposes, for light, or for electroplating, and, as experimentally shown in the lecture, to generate the current locally in the two latter cases by using the motor to drive a suitable dynamo, thus giving the first illustration of the employment of an electric transformer in the actual transmission of power to a distance.

Two years later, viz in 1881, the old mistaken notion, that it was only 50 per cent of the power given to a dynamo that could be returned by the motor, was again propounded during a discussion at the Society of Arts; and the Chairman, Sir W Siemens, when correcting the speaker's error, added, "Experiments of undoubted accuracy had shown that you could obtain 60 or 70 per

cent In this year two very important propositions were put forward—the one, by Sir W Thomson, at the semi-centenary meeting of the British Association, that, in the electric transmission of power, the small current of high potential difference should be employed at the receiving end of the line to charge a large number of accumulators in series, the accumulators being subsequently discharged in parallel for supplying light or power to a town; the other, by MM. Deprez and Carpentier, to use one alternate current transformer at the sending end to raise the electric pressure, and another transformer at the receiving end to lower it down again, the arrangement being symbolically shown in Fig. 1

Fig. 1 - Deprez and Carpenture's Plan of Double Transformation

The great advantage of this combination is, that the pressure along the line may be very high, and the line therefore composed of only thin wire, whereas the pressure between the leads from the generating dynamo at the transmitting end, as well as the pressure between the lamp mains at the receiving end of the line, may be as low as if the dynamo and lamps were close together

In the experiments, however, made in the following year, 1882, to transmit power from Miesbach to Munich, along thirty-five miles of iron telegraph wire o 18 inch in diameter, the current going by one wire and returning by another, M Deprez did not employ his double transform ing arrangement described above, probably because alter nate current motors were then quite untried practically But, instead, he used a direct current dynamo generating a potential difference of some 1500 volts, the current from which set in motion a direct current motor, wound to stand a similar high pressure, placed at the other end of the telegraph line

The experiments were attended with various breakdowns of the dynamo, which was probably constructed on the usual string-and-glue fashion of those days; and finally, after repairs had been effected, the power given out by the motor at Munich was only a fraction of I horse, with a commercial efficiency of about one-third

It was, therefore, decided to repeat the experiments the next year, 1883, with machines constructed more solidly, and for the convenience of the jury the dynamo and motor were placed close together in the workshops of the Northern Railway near Paris, one terminal of each being connected by a short wire, and the other terminals by a telegraph wire 0 157 inch thick going from Paris to Bourget and back again, a distance of 18,133 yards. The power used in driving the dynamo was towards the end of this second set of experiments about 10 horse, and the power given out by the motor about 31 horse, the potential difference at the dynamo terminals being some

The arrangement of the machines was very bittely criticated some pronounced the result a great success, others that the whole thing was a fraud, that the power did not up from the dynamo at Parist Bourget and back again, but that, owing to leakage from one of the telegraph lines to the other, the actual distance over shich the power was transmitted was far less than the distance stated

The next experiments were made with the same machines rewand and improved in insulation. They were now employed to traismit power rove #P miles, from Varille to Greate the same and a connect the dynamic and motion. A difference of potential of hosting you volks was employed, and 7 hoise-power was given off by the motor was a commental of flowing you will be with a commental of flowing you will be with a commental of flowing you for great of the will be with a commental of flowing you for great or with a commental of flowing.

This experiment of transmitting power from Vielle to Grenoble in 1833 was distinctly successful, and constituted a great advance on anything in electric transmission that had been attempted before. It is interesting, for example, to compare it with the transmission from Hirschau to Munich by Mr. Schuckertin 1882, and which was regarded as very stitling at the time if was carried on the second of the secon

Transmission of Power

	1832 Harschau to Munich	Vizille to Grenoble
Distance in miles	32	84
Diameter of conducting wire to inches	o 18	0 079
Horse-power delivered by electromotor	5 8	7
of the transmission	36	62
Potential difference at terminals of dynamo in volts	700	3000

Compaining, then, the Vizille transmission of 1883 with the Hirschau transmission of 1883, we see that the distance was time to expect the cross-section of the wire less than one quartet, the power somewhat greater, and the efficiency nearly twice as great, this preat improvement being effected by using a pressure of 3000 instead of 700 volts.

But with 3000 volts the limit of constructing the commutator of an ordinary direct current dynamo or motor is reached—a fact which was not appreciated by M Depree. For when it was decided somewhat later to try and transmit 200 hore-power through 230 stelegraph poles between Creal and Paris, by using a pressure of 6000 or more volts, the same system of direct current dynamo and motor, that had been employed by M Depres in his previous transmissions, was resorted to. The result was the dynamo and motor were burnt up time after time.

Eventually, after the expenditure of a very large sum of money, spent in several rewindings of the machines, &c., M. Dejrez succeeded in 1886 in obtaining from the shaft of the motor at Pairs 52 lourse power, this being 45 per cent. of the power spent in driving the dynamo at Credi. The power delivered at Pairs was distributed by coupling a low potential differences at Pairs with the Coupling a low potential difference, the dynamo for driving various smaller motors, so by this dynamo for driving various smaller motors, so that the power actually delivered to the pumps, &c., was somewhat less than the 52 hores stated above.

In the use of a dynamo and motor each with a high resistance armature and a low resistance field magnet, the fields being produced by separate excitation, and in the employment of a motor-dynamo for utilizing the received power, M. Depret expressed his approval of the very

NO. 1144, VOL. 44

plan proposed by Profs Ayrton and Perry in 1879 for "sending by even quite a fine wire a small current," and so obtaining "an economic arrangement for the transmission of power

direct current ought to be used. While these various experiments of M. Deprez with direct currents were being carried out, the transmission of power by means of alternating currents lad been prosented on the control of the control

Nobody thought much of the "secondary generator", it seemed to have no very special use, the tron over felt very hot, so that there would be a new waste of power introduced mot electric lighting by the use of secondary for the s

But Messrs Gaulard and Gibbs believed in their secondary generator, whatever electricians and the secondary generator, whatever electricians and the Notting IIII Gate, Edgware Road, Gower Street, King's Cross, and Aligate stations of the Metrupolitan Railwoy, joined the fine wire coils of all the generators in servit one another, and sent a small alternating current through the whole curcuit from a bytome placed the thick wire coils of sach of the generators at the five rulway stations burned steadily and brightly; an alternate current motor, even, which was put at one of the stations, revolved rapidly but what a great waste of your form of the stations, revolved rapidly but what a great waste of your forms of the stations, and the sunce-scany transformation, and

Well, in the spring of the next year, 1884, Dr J Hopkinson tested the efficiency of these secondary generators on the Metropolitan Railway, and, to the surprise of nearly everyone, it came out close on 90 per cent

In the autumn of the same year, in connection with the Exhibition at Turin, power was transmitted to Lanzo, twenty-five miles away, by means of a bare overhead wire rather less than one-quarter of an inch in thickness, and, by means of Gaulard and Gibbs's secondary generators, the foundary of the properties of the transformers was 89 per cent, the whole distribution strikingly successful, and a pute of 10,000 france was awarded to Messrs Gaulard and Gibbs by the Italian Government

No electromotors, however, appear to have been driven by the transmitted power, for, even in 1884, alter-

nating current electromotors were still comparatively untried.

"Tests of a secondary generator were next undertaken in 1855 by Prof Galike Ferrans, of Turn, who found the efficiency at full load to be no less than o'; per cent,—a value even higher than that previously published. This messigation is the more memorable, in that it led Prof. Ferraris to take up the mathematical and experimental investigation of alternating currents, resulting in the discovery and construction of the self starting alternate covery and construction of the self starting alternate experimental investigation of alternating currents, resulting in the discovery and construction of the self starting alternate secondary generators, now called transformer. And so one of the chief lions this year at the Frankfort Exhibition was Prof. Ferraris.

(To be continued.)

THE GIRAFFE AND ITS ALLIES.

ALTHOUGH coming within that well-defined group of ruminants known as the Pecora, the Giraff (the sole existing representative of the genus Giraffa) stands markedly alone among the mammals of the present epoch; although, on the whole, its nearest living relations appear to be the deer (*Cervude*) Moreover, not only is the giraffe now isolated from all other ruminants in respect of its structure, but it is also ex-clusively confined to that part of the African continent which constitutes the Ethiopian region of distributionists. When, however, we turn to the records of past epochs of the earth's history, we find that both the structural and distributional isolation of the giraffe are but features of distributional isolation of things Thus, in regard to its distribution, we find that in the Pliocene epoch giraffes were abundant in Greece, Persia, India, and China, and were abundant in Greece, Persis, india, and China, and we may therefore fairly assume that they were once spread over the greater part of the Palicarctic and Oriental regions Then, again, with regard to their allies, the researches of palicontologists have been gradually bringing to light remains of several large extinct ruminants from various regions, which are more or less nearly related to the giraffe, but whose affinities appear to be so complex and so difficult to decipher, that not only do they remove the stigma of isolation from that animal, but even render it well-nigh impossible to give a definition of the group of more or less graffe-like animals, by which it may be distinguished on the one hand from the deer (Cervidae), and on the other from the antelopes (Bornda) Since an interesting account of a new extinct Graffoid from the Phocene deposits of Maragha in Persia has been recently given by Messrs Rodler and Weithofer in the Denkschriften of the Vienna Academy, the present time is a suitable one to offer a brief résumé of the present state of our knowledge of this aup of animals, and the different views which have been

entertained as to the affinites of some of its members. Among the chef structural pecularities of the graffe, the most noticeable is its great height, which is mainly produced by the excessive length of the neck and himbs. The fore-limbs are, moreover, longer than the hind ones, as is well shown by the crucimistance that the radius, or condition obtains. The shell is more like that of the deer than of any other existing runmants, this being shown by its general contour, and also by the presence of the large unosafied space below the eye, which completely expertise the Hachymal from the nast bore; a consequence of the shell present the shell present the sell of such conditions of the protein studied behind the eyes, fe the particular feeding in the skull of the bony processes arising from the skull of the support of the portion situated behind the eyes, fe the particular feeding.

between the occiput and the eyes, and clothed in the lung animal with skin, are not strictly comparable either with the antiers of the deer or the hort cores experienced by the control of the skill, with which, however, they unite as age advances. The whole of the frontal and nasal region is much swollen and inflated by the development of air-cells between the inner and outer massal bones there is a large oval hillock-like protuberance in the middle line, which is sometimes termed a third horn. This excessive instation of the region of the face of the control of the state of the control of the face of the control of the face of the fa

Since a good deal depends on the similarity between the structure of the molar test of the graffe and those of the extinct runmants in question, it may be well to observe that the characters of the molar test hamong all the runmants are of great importance in classification. Thus, these tested in all the deer, although varying to a sent the same general structure, those of the upper jaw being comparatively short and broad, with a large internal additional column. Then, again, in the Brounds we may notice that each of the several groups into which the antelopes are divided, as well as the goats and sheep and the ozen, are severally distinguished by the characteristic of the same group may approximate more or less closely to that of another, we do not find any instances where one member of a group possesses teeth of a totally different type from those of the other perspectatives of the same group. These facts strongly indicate that, when we meet this fost in unmants having molar teeth of the very wind to strong that there must be a certain amount of relationship between the owners of such teeth.

Another marked peculiarity of the grinffe is that the humerus has a double grove for the biceps muscle, instead of the single one found in ordinary ruminants. In regard to its soft parts, the graffe resembles the deer in the usual absence of the gall-bladder, although its reproductive organs are constructed more on the Boyne type

With these preliminary remarks on some of the structural peculiarities of the graffe, we may proceed to the consideration of its fossil allies. The genus which probably comes mearest to the graffe is the imperfectly known the Phocene of Burna, but to which have been referred meaning the properties of the Punjab. This animal must have been consectably larger than the graffe, and the upper molars and bones from the corresponding beds of the Punjab. This animal must have been consectably larger than the graffe, and the upper molars of their external columns, in which respect they come nearer to the corresponding test the of the like has do those of any other members of the group. The postenor cannon-bone, or mentaturas, assigned to this genus, some elongated and graffe-like than those of any other fossil genus in which this part of the skeleton has been described. The cervical vertebrar are also more elongated and graffe-like than those of any data one of early other fossil genus in which this part of the skeleton has been described. The cervical vertebrar are also more elongated and graffe-like than those of any data one of early other themselves the properties of the skeleton when the corresponding data of the properties of the skeleton when the same than the corresponding that the skeleton has been described.

circumstance that they indicate the existence of an animal to a great extent intermediate between the giraffe and the following genus.

The genus 'Islandsheruum was established upon the remains of a large grafted like rumman from the Pikermi beds of Greece, to which a skull from the Indian Swalks, which had been previously regarded as referable to the female of Swalksherum, proved to belong. The above the stable of the stable of

The animal recently described by Messrs Rodler and Wethofer from the Persian Plococne, for which the bybrid name Aliusphalis has been proposed, tends to connect the Idealochiere with the deer, and more established the server in the deer, and more established the server in the server in the server in the health of the radius and ulm being nearly the same. Then, again, from the total absence of nir-cells in the frontal region of the skull, the middle of the face is nearly flat, and the orbits have their frontal borders in the plane of the face, and still more so in the granter. There is, however, no unossified space in front of the eye, although the whole contour of the skull is strikingly eli-like

The conclusion to be drawn from these hornless forms appears to be that they serve to connect the graffe with less absertant ruminatists, and more especially the Corvoids, and the control of the control of the corvoids and the probability and acquired country in the control of the control o

Leaving now these hornless forms, as to the affinities of which there has been no dispute, we have to turn our attention to another group provided with cranial appendages of very curious and still imperfectly understood structure, in regard to whose relationship exceedingly different views have been entertained. This group, so far as we know at present, seems to be confined to the Phocene of India and Persia, being represented in the former area by the gigantic Sivatherium, Bramatherium, and Hydaspitherium, and in the latter by the much smaller Urmiatherium In all these animals the skull is characterized by the extreme shortness of the parietal region, and the position of the horns or antlers immediately over the occiput; the elevated facial profile thus produced being in very striking contrast to the straight one of the deer. In Bramatherium and Hydaspitherium the cranial appendages rise from a massive common base, and the latter genus is distinguished from all the others by the presence of an unossified space below the eye, corresponding to that of the graffe. Their molar teeth are very similar to those of the Helladothere. In the Sivathere, on the other hand, there is one pair of large branching and palmated cranial appendages rising from separate bases imme-diately above the occiput; and in addition to these a pair of much smaller conical ones placed immediately over the orbits In general appearance the large palmated appendages are more like the antiers of the elk than those of any other existing ruminants, but the absence of a "burr" at their base indicates that they were not deciduous, while the deep arterial grooves on their surface suggest that they were clothed either with skin or with a horny substance. The molar teeth conform to those of the giraffe-and to a less degree the deer-having the same rugose enamel: but the ridges on the outer surfaces of those of the upper iaw are more developed than in the other extinct genera. A pecularly giraffe-like and cervine feature in these upper teeth is the extension of the anterior extremity of the anterior crescent far towards the outer side of the crown Lastly, the humerus of the Swathere resembles that of the giraffe in the presence of a double groove for the biceps muscle, while the form of the terminal bones of the feet is almost identical in the two animals. In the small Persian Urmiatherium, which is known only by the hinder portion of the skull, it appears that the cranial appendages consisted of a pair of unbranched, somewhat compressed, and upright processes rising immediately above the occiput

With regard to the affinities of this group, it has been argued that the shortness of the parietal region of the skull, and the position of the cranial appendages immediately above the occiput, indicate affinity with certain African antelopes, such as the Sassabi and its kindred (Aliceaphus). In that group of antelopes it is, however, perfectly clear that the features in question are acquired ones, the allied Blessbok scarcely possessing them in any degree. Again, the straightness of the cranial axis in the skull of Waller's gazelle (Gazella svaller) shows that the arching of this axis, which is so characteristic of most antelopes, is likewise a feature specially acquired among that group of animals Moreover, apart from this evidence, no one who thinks for a moment on the sub-ject can believe that the Sassabi, with its narrow sheeplike molars and true horns, and the Sivathere, with its broad giraffe-like molars and cranial appendages, which are neither true horns nor true antiers, can be anything approaching to first cousins, and yet if they are not so, it is perfectly evident that the similarity in the structure of their skulls must have been independently acquired. It is therefore abundantly clear that no arguments based on these resemblances will hold water, the true explana-tion probably being that the superficial similarity of their skulls its solely connected with the support of cranial appendages having a similar position in both groups

It follows from this that, if a type of skull with a short parteal region, a curved basia axis, and horns placed immediately over the occupit, has been independently parteal region, a curved basia axis, and horns placed immediately over the occupit, has been independently along parteal reson, between the said axis, and horns placed over the orbits, there is no conceivable reason why a similar line of development should not have takens place among graffe-like animals. Taking, therefore, into teeth like those of the graffe, that their cranal appendages could be derived from those of the latter by special modification and development better than from those teeth like those of the graffe, that their cranal appendages could be derived from those of the latter by special modification and development better than from those the said of the sa

The writer has purposely refrained from making any reference to the large unossified suborbital vacuity in the skull of the Hydaspithere, as reasons have already been

526

given for regarding that feature as an acquired one If, however, that view be incorrect, the presence of this vacuuty at once studies the statement that the Sivathere can have no kinship with the giraffe and the deer, on account of the absence of a similar vacuuty, and its presence, so far as it goes, is also another argument against the Sassabi theory.

"The last representative of the Girafford animals that we have to mention is the recently discovered Sametherium, from the Phocene of Samos, a figure of the skull of which appeared in NATURE, illustrating an article on the extinct mammals of those deposits. In this animal, the elongated form and straight profile characteristic of offerm and straight profile characteristic of almost indistinguishable from those of the latter. There is, however, no development of air-cells in the bones of the frontal region, so that the upper border of the orbit is approximated to the plane of the face, and the cranial appendages take the form of upright compressed propendages, which appear to have been inseparable from the bones of the forchead, are, indeed, very similar, both in form and position, to the horn coses of certain extinct antelopes, but we are, of course, unacquainted with the anative of their covering. If, however, as seems to be enaute of their covering. If, however, as seems to be anative of their covering. If, however, as resents to be anative of their covering. If, however, as resents to be anative of their covering. If, however, as resents to be accessed as the seems to be such as the covering of the properties of the such as the covering of the properties as one independently forcid resemblance to the antelopes as one independently.

acquired
Finally, if the views expressed above are anywhere near the truth, it would appear that, in the Phocene epoch, Grafford animals played a very important relleament of the property of

PHOTOGRAPHIC MAGNITUDES OF STARS.

THE character of the image of a six photographed on a sensitude film, three-iten between the intensity of the light photographed and the blackened disk produced, the indience of the time of exposure on the image—are questions now receiving much attention. For this reason, Dr. Schiener's contribution to the subject, embiracing, as if does, the latest results of the Fotsdam will not be accepted without great reserve, contravening, as they do, a theory, or at least an assertion, that has been very generally accepted, vir that increasing the intensity of light is exactly equivalent to increasing the intensity of light is exactly equivalent to increasing the intensity of light is exactly equivalent to increasing the intensity of light is exactly equivalent to increasing the intensity of light is received.

Such a law cannot be rigorously exact, and its stoutest supporters have been careful to confine its application "within limits." But Dr Schemer's contention is that, owing to the complex character of the disk produced on the filtingatch a principle is a very unsafe guide, either as a rule for the determination of the feebbear magnitude impressed on the negative, or as offering a satisfactory explanation of the growth of the dameter or area.

In the first place, there is evidence of want of uniformity of actinic action throughout the whole extent of the stellar disk. A mean intensity (i) may be assumed at a certain distance (r) from the centre of the image, where the intensity is 1. This centre will not be a geometric distance (r) and the centre of the intensity of the intensity of the current of the intensity of the current of the intensity (r) at distance (r) will depend materially on the increase of the area (p), which may be represented by $\psi(p)$. Consequently, the simplest expression for $-1\psi(p)e^{\mu r}$, where a is the confliction of absorption formed on the same emulsion, and treated by the same developer, this cryptession become

$$\frac{I_0}{I_1} = \frac{I_1}{I_0} \frac{\psi(\rho_i)}{\psi(\rho_0)} e^{a(r_1 - r_0)},$$

and, if the disks be on the same plate, $\rho_1 = \rho_0$ and $t_1 = t_0$, so that the formula can be simplified to

$$a(r_0 - r_1) = \log \frac{l_1}{l_0} - \frac{0.4}{\text{mod}} (m_1 - m_0)$$

In order to derive the relation between diameters and exposure, put $I_o = I_i$, and then

$$\log \frac{t_0}{t} = a(r_1 - r_0)$$

It is not likely that such an expression has any other value than to serve as a convenient formula for interpolation. The variable character of a under different conditions, but always depending on the time of exposure, is shown by the following table.

1 xp	Ostire	Instrument	a	Instrument	a
t ut		Reflector	4 99	5 in refractor	4'12
2	0	,,	4 57	**	5 09
8	0	**	4 67	**	5 47
	0	**	4 89	**	5 89
16	0	,,	5 39	13-in refractor	7 51
0	24	13-in refractor		13-in refractor	
	0	,,	3 16	,,	2 20
	30	,,	3 33	11	2 48
6	15	**	3 33	,,,	3 00
15	28		4 48		****

Another well known formula in which magnitude is made to depend on diameter is $m=a-b\log D$, and in this case b is shown, notwithstanding Dr. Charlier's results to the contrary, to be a function of the time of exposure The results are as follows.

Time of	Charber	Time of exposure.	Scheiner
h m	Chartier	m s	Generati
0 13	6 719	0 24	5 17
1 30	6 779	1 0	6.32
2 0	6 683	2 30	7 06
3 0	6 814	6 15	8 o8

The disagreement is conspicuous, but the explanation offered by Dr. Schemer is scarcely satisfactory. He would ascribe the constancy in the value of \(\ell \), found by Pr Charlier, to the fact that in his experiments there is always a large absolute value of the tume coefficient. It can be always a large absolute value of the tume coefficient of the company of t

If it be admitted that the product of intensity by the time is not a constant quantity, it becomes a matter of great practical importance to determine what is gained on a photographic plate by prolonged exposure. This question forms the real investigation of Dr. Scheiner's two papers, and though some of his results may be questioned, yet the general issue is so grave and disquieting that it may not be utterly ignored. Passing over the details of his method of examination, and the precautions taken to mayer accurate results, for which the reputation

of the Potsdam Observatory is a sufficient guarantee, Dr. Schemer presents the following table, in which is exhibited the faintest magnitude which, under certain varied circumstances, can be detected on a photographic nlate.—

	Time of ex	posure,		Faintest	magnitude	
	ın		Plate I	Plue II	Plate 11t	Plate IV
	0 :	24	90	64	7 7	8 2
	1	0	9.4	7 25	8 3	8 75
	2	30	99	7.7	8 55	93
٠	6	15	10 6	8 45	9.3	965
	15	38	****	8 85	9.7	

It will be noticed that while each successive exposure is 25 that of the pieceding, the corresponding gain in light is considerably less than one magnitude From each of the four plates the gain is as follows.—

The mean is 053—that is to say, instead of one magnitude being gained by continued exposure through each successive interval, the actual gain is only half a magnitude The exception that might be taken to these experiments is, that the detection of the feeblest stars on a plate is a matter of doubt and great practical difficulty. Dr Scheiner has, however, availed himself of a second To Scientific mass, nowever, availed infinise of a second test by counting the stars on a plate after various exposures. With this view two plates were taken of the region round of Orionis, one with an exposure of one hour, the other with eight hours' exposure. Therefore, if 25 the other with eight hours' exposure. Therefore, if 2 5 times the exposure produced stars a magnitude fainter. times the exposure produced stars a magnitude radiiter, there ought to be a gain of more than two magnitudes on the second plate, and it may be assumed that the number of stars impressed would follow the known law. On the one-hour plate were found 1174 stars, on the eight-hour There ought to have been on the long-exposed plate over 10,000 stars, so that roughly speaking only onehalf of the stars given by the law were photographed Further, Argelander has catalogued within this area 125 stars, and therefore it might have been anticipated from the law of increase that some 10,000 stars would have been visible on the one-hour plate

This margin is too great to be readily explained away of course, there is the same difficulty in perceiving the mutte dots that represent the faintest stars as in the former case, and further, it is possible that the law of average increase of the number of stars did not hold in a verage increase of the number of stars did not hold in that a law, which applies with more or less accuracy on the average to the whole of the sky, is necessarily fulfied on any small portion, such as the ten-thousandth part. If the stars are not in the heavens, they cannot be photographed. Evidently, it would be unlikely that thousandth part of the total number of stars impressed. But allowing for errors of exaggeration and observa-

But allowing for errors of exaggeration and observation, the result is very interesting, and not a little alarming as implying that sphotography is not so powerful an engine as was at first anticipated, and that, to accomplish the full hope of all that was expected of it, longer exposure and consequently a greater expenditure of time will be that if a star of the 95 mag be registered in 44 seconds, then in 150 minutes a star of the 165 mag will be photographed, supposing a whole magnitude to be gained by successively multiplying the exposure by 2 5 but if the gain be only 05 in this interval, then the fanites's star impressed will be only 130 mag, even after this long that of the 150 mag, but the continue of the 150 mag. The the 150 mag will be solony 150 mag, even the tribusion of the that of the 150 mag. The the 150 mag will be solony to the 150 mag. The truth will probably be found near this latter limit. NOTES

This econd International Folk Love Congress meets at the rooms of the Society of Antiquaries this afternoon, when an address will be delivered by Mr. Andrew Lang, the President, Three subjects are to be considered—folk tales, mythology, and mutations and customs. To each of these subjects a day will be devoted. The proceedings will be brought to an end on Wednesday morning next.

1111 Iron and Steel Institute will meet at the Woolwich Arcent on Tuesday nest. The members are to be conducted over the manufacturing departments at the Arsenal, and will see quick firing and machine guns in practice. On the following day the Institute will conclude its meeting at the Institution of Civil Regineers.

First third blennial session of the International Statistical Congress was opened at Victina, on Monday, by Baron Gautsch, the Austrain Minister of Public Instruction An address was delivered by Sir Rawson, the President

This seventeenth Annual Congress of the Santary Association of Socioland was held in Fullmolly last week. Dr. Farquhar son, M.P., President of the Congress, delivered an address "On a Nobel Hygienes State, or a Galinear at the Santation of the Future." In the course of his remarks he urged the necessity for more organized attention being given in Parliament to Mygienic matters, and advocated the appointment of a Minister of Pablic Leading and Congress of the Congress of the

THE Harveian Oration will be delivered at the Royal College of Physicians, by Dr. W. II. Dickinson, at the Royal College of Physicians, on Monday, October 19, at 4 o'clock

WE referred last week to the death of Prof W Ferrel was born on January 29, 1817, and since the foundation of the American Meteorological Yournal he was a frequent contributor to that paper, from which we take most of the following details of his life. During his boyhood he was kept rather closely at work on his father's farm, and with the first money he earned, he bought a copy of Park's "Arithmetic" Having also a liking for istronomical studies, he used to draw a number of diagrams upon the doors of his father's farm, describing circles with the prongs of a pitchfork. In 1839, he entered one of the Colleges in Pennsylvania, and graduated at Bethany College in 1844. In 1857, he became an assistant in the office of the "American I phemeris and Nautical Almanac," and subsequently entered the U.S. Coast Survey and the Signal Office, from which last he retired in 1886. He was elected a member of the National Academy of Sciences in 1868 Ferrel is described as an extremely diffident man, and he never once sought position, every official position that he occupied having been offered to him His first paper bearing directly on meteorology was published in 1856, with reference to the deflective effects of the earth's rotation upon the motions of the atmosphere; and this paper, which has done much towards establishing meteorology on a scientific basis, was subsequently revised and reprinted as one of the professional papers of the Signal Service, under the title "Motions of Fluids and Solids on the Earth's Surface" In this treatise he proposed a complete analytical investigation of the general motions of the fluids surrounding the earth These papers received considerable attention and discussion soon after publication, especially in France, in America and England they were overlooked until recent years, but they are now recognized as fundamental propositions in the study of meteorology. He also wrote various articles on the tides, which are of equal significance with those on the motions of the aimosphere, and he constructed a "maxima and minima tidepredicting machine." which is now in use at the Coast Survey Office in Washington The last of his numerous works upon meteorology was a "Popular Treatise on the Winds," published

in 1889, and reviewed at length in our columns (vol xli, p. 124). In this work he has explained at length, and with great clearness, many points which in his other writings have been too mathematical to allow of their being generally understood.

WE have already recorded with regret that Miss E. A. Ormerod has considered it desirable to resign her post of Consulting Entomologist of the Royal Agricultural Society, which she has occupied for about nine years, having been appointed in 1882 We understand that her reasons for resignation are partly on account of health, as in wet and cold weather she cannot take the requisite journeys to attend Committees without risk; partly on account of claims made of power of Council to direct her to render service in reporting elsewhere, and claims also made as to use of information in her possession beyond what the terms of her engagement granted These claims, we understand, have been withdrawn, but Miss Ormerod considers she can work more efficiently when freed from the anxieties and possible ties which public office necessarily brings with it. Miss Ormerod's agricultural entomological work, as shown by her annual reports has now been going on steadily for at least fourteen years, having been begun several years before she was elected to the staff of the Royal Agricultural Society, and this she purposes to continue precisely as before in all respects, whether as regards replies to inquiries, or publication by herself of observations in the form of yearly reports

In an article on Hooker's, "Icones Plantarium," in our last issue (p 498) we attributed the plates of the earlier volumes to Sir William Hooker Sir Joseph Hooker informs us that they are all the work of Mr. W. H. Pitch

A VALUABLE report, by Mr A E Shipley, on an orange disease in Cyprus, caused by a scale insect, is published in the September number of the Kew Bulletin The disease appears to have been noticed in Cyprus for the last six or eight years. The particular insect to which it is due is Aspidiotus aurantis, Maskell, a member of the sub-family Diastonic, which with some others, compose the family Coccide. Mr Shipley gives an account of the life-history of this insect, and then describes the various methods of dealing with it. The most successful of these methods is the gas treatment, a full description of which, by Mr Coquillett, Is quoted by Mr Shipley from Bulletin No 23 of the U.S. Department of Agriculture, Division of Entomology. We may note that Mr Shipley is anxious to obtain examples of Cocoda which infest plants, and examples of nematode worms parasitic in plants, with the affected parts of their respective hosts.

THE Kew Bulletin for September, besides Mr. Shipley's report on orange scale in Cypria, contains sections on the reducovery of gutta-percha trees at Singapore, on a new process for recovering some portion of the gutta-percha which is left in the bark of the trees after collection by the ordinary native method, on the fodder plant Tagassate, and on Kangra buckwheet.

THE Oesterreschische Botanische Zeitung for September contains a report of Dr. A. v Degen's botanical excursion to the island of Samothrace, and of Dr. R. F. Solla's to Southern Istria.

This fourth number of the first volume of Contributions from the U.S. National Harberium, published under the suspices of the Department of Agriculture at Washington, consists of a description, by Mr. J. N. Rose, of the plants collected by Dr. E. Palmer in 1890 in Western Mexico and Arzona. Forty-fire ever species are described, and several of these are tillungrated by plates. Most of the new species obtained were from the neighborarhood of Alamon, a miling town of about 10,000

mhabitants, sunated 180 miles south-east from Guaymas, at an altitude of about 1275 feet, where there are both a dip spring and a ramy autumn flora, very different from one another. Dr. Palmer has again started for a year's exploration of Western Mexico

SOME valuable and interesting notes on the fertilization of Sonth African and Mandgascar forbering plants by Mr G. F. Sont Elliot, appear in Armale of Botary (vol. v., No. xix, August 1891), and have also been issued separately. They represent much work done during a two years' botanical trip. While travelling, Mr Elliot found it impossible to make as thorough and complete observations as are really required for a proper comprehension of all the adaptation of a flower to invested in the section of the section of the daptacetion of all the adaptation of a flower to investing flowers, and brought home with him a numbered collection Mort of the forms secured by him had not previously been studied in their native haunt.

THE TRANSACIONS of the Laverpool Biological Society for 189; contain an important paper by Mr. G Muray on the Distribution of Manne Algevin space and in time. The author compares the agial flow of three widely separated regions—the Arctic Sea, the West Indian region, and Australia, and shows in a table how many genera and species are common to any two of the regions. The number of Knows species of seaweds is given as 259 in the Arctic Sea, 585 in the West Indian, and 1133 in a Australia. Only twelve species are common to all three regions, and of these four belong to the Ulwin Indian.

A GREAT Mining Exhibition is to be opened at Johannesburg next July, and exhibits from all parts of the world are invited

This administration report of the Manne Survey of India for the official year 1850-0-1, by Captum R F Hoskyn, has been published. For some time notices had been received from several vessels, which seemed to indicate that the shoals Jung off the eastern coast between Ensore and Pulscat were extending seward. In the early part of 1850, therefore, the Parentinguer proceeded to the neighbourhood, and made a survey of the coast between these two places, carrying the soundings out to the too-fathom line. The result aboved that no material change that had been seen to the seven the server of the server of the theory of the coast of the server o

THE report of Dr. A. Alcock, surgeon-naturalist on board the Investigator, is one of great interest. It is given as an appendix to that of Captain Hoskyn. We have already referred to Dr. Alcock's account of the general results of his deep-sea work It may be noted that on November 3, 1890, the deepest haul ever made in Indian seas-1,997 fathoms-was successfully carned out in lat. 9° 34' N., long. 85° 43' 15" E., the bottom being Globigerina ooze with pieces of water worn pumice, and the bottom temperature being 35° F. About 2200 fathoms of wire were veered. The following was the entire take .- There were three species of sillceous sponges and numerous detached spicules of Hyalonema, a large sea-anemone of a salmon-pink colour, with bright red tentacles; a mutilated specimen of the Brisingoid Freyella benthophila, Sladen, a fine new species of Hyphalaster, and a small, probably new, species of Marupaster with the midamental pouches widely open and full of ova; two species of Ophinrids, one of which is Ophiomastus, three species of Holothurians including Echinosoma; numerous specimens of a long-stalked Ascidian; two specimens of a very large species of Amphipod, a blind Crangonld, three species of macrurous Crustaceans, and a small Scapellum; a small Lamellibranch; and a number of empty annelid tubes, some of which were constructed of Foraminiera shells, while others consisted of agglutinated silky (siliceous) threads

Ms. W. L. Dallas, assistant meteorological reporter to the Gorenment of India, has written a valuable paper on the meteorology and climatology of Northern Afghanstan, the facts having here collected by offices, and the Afghan having here collected by offices, and the Afghan the consideration. Taking the wind like Afghan the consideration, Mr Dallas thus it may visible be mint atmed that in the great majority of cases the disturbed wealthe which appears over North Western India during the winter and spring months is the result of disturbances, which either effect assimilations of the whole region comprising Afghansian. Balachstan, and North-Western India, of which have appeared first over Afghansian and secondly over India, and that these disturbances have seldom originated in India stelf or asseconfied to India.

WE have received from the Meteorological Council their Quarterly Weather Report for July to December 1880, and Monthly Weather Report for May to December 1887 Quarterly Reports, which commenced with the year 1860. contain, in addition to the monthly and five-daily means of the observations made at the seven observatorics, plates of the continuous curves of the self-recording instruments, which have been etched at the Office, and are perhaps the most complete and perfect series of meteorological curves hitherto published, and also a condensed account of the most important meteoro logical changes of the period The Quarterly Reports are now discontinued, and the publication of a Monthly Weather Report was undertaken in 1884 in substitution for the Onarterly Report, while the hourly observations and means have been published in a separate volume. This Report contains the results of obwith a chronicle of the weather, and charts showing the average conditions of the various elements. Both the Quarterly and Monthly Weather Reports also contain a number of claborate discussions of various allied subjects The Monthly Reports in the form hitherto issued have been modified, and instead of appearing as a separate work, a Monthly Summary of the Weather, on a more concise plan, has been added to the Weekly Weather Report, commencing with the year 1888 With the exception of the years 1881-83 we have therefore a continuous and valuable record of the weather-in addition to such as is afforded by the Daily and Weekly Reports-since 1869, and we believe it is the Intention of the Council to connect the gap between the Quarterly and Monthly Reports at an early date, by a discussion of the weather for that period. We shall refer in a future number to the publications which deal with the observations and results at the Stations of the Second Order, which are more particularly of a climatological character, without discussions of current weather.

The Park Communication of Boston, U.S., have set apart three parcels of land for the testablishment, by the Boston Society of Natural History, of soological gardens and aquasis. It is essential that soo, coo dollars should be raised before may stempt can be made to realize the scheme as a whole, but if a third of the amount were subscribed, one of the two proposed aquasis might at once he instituted. An appeal has been made by the Society to the people of Boston for the necessary finds, and it will be strange if it does not more made, but have a subscribed to the scheme that the state of the people of Boston for the necessary finds, and it will be strange if it does not more made, but his that care public-pipirted client will see in the scheme "an addition to the forces which increase the intelligence of the voter, and thereby tent to make Boston a more desurable place of readence."

STUDENTS of the Ice Age will read with interest a paper by Mr. N. S. Shaler on the antiquity of the last glacial period, submitted to the Boston Society of Natural History, and

printed in the latest instalment of the Society's Proceedings. Mr Shaler differs decidedly from those geologists who suppose that the end of the glacial period is probably not very remote from our own day. One of the strongest of his arguments is derived from the distribution of the vegetation which in America has regained possession, by migration, of the glaciated district. We must conceive he points out, that as the ice retreated and gradually disappeared from the surface a considerable time claused before existing forests attained their organization. He assumes as certain that the black walnut and the pignut bickory, between Western Minnesota and the Atlantic coast, have advanced, on the average, a distance of 400 miles north of the ancient icc front to which their ancestors were driven by the presence of the glacial sheet For several reasons he believes that the northward progress of these forms must have been due mainly, not to the action of streams or tornadoes, but to the natural spread of the seed from the extremities of boughs, and to the carriage of the seed by rodents. But allowing for every conceivable method of transportation, he argues that a period of ten or even twenty thousand years is wholly inadequate to account for the present distribution of those large-seeded trees. If they occurred only sporadically in the northernmost part of the field they occupy, their implantation might be regarded as due to chance action. I he fact, however, that they extend from the Atlantic to Minnesola indicates that the advance was accomplished by causes of a general and continuous nature

"WATER BIRDS that live in the Woods" formed the subject of an interesting paper read lately by Mr. C. B. Sennett before the Linnesn Society of New York About a dozen species were dealt with, the most interesting of them perhaps being the tree ducks (Dendrocygna autumnalis et fulva) The former is found in the heaviest timber along the Rio Grande of Texasat Lomita, and as this river furnishes no sort of food, it adapts itself to circumstances and leeds upon seeds or grain ducks will alight upon a stalk of growing corn with the ease of a blackbird, and are quite at home among the lofty trees where they make their nests. They do not resort to the river, which is so cold and muddy, from the melting snows of the mountains whence it flows, that all vegetable and animal life save the garpike is wanting. No ducks of any kind are found upon it. flock of cormorants, about four miles long and one mile and a half wide, was once seen by Mr Sennett in Minnesota.

SPARROWS do not seem to lose in New Zealand any of the audacity for which they are famous in Europe. In a paper read some time ago before the New Zealand Institute, and now printed in the Transactions, Mr T W Kirk gives an example of what he calls their "daring and cool impudence" Between I catherston and Martinborough he heard one day a most unusual noise, as though all the small birds in the country had joined in one grand quarrel Looking up, he saw a large hawk (C goulds-a carrion-feeder) being buffeted by a flock of sparrows. They kept dashing at him in scores, and from all points at once. The unfortunate bawk was quite powerless, indeed, he seemed to have no heart left, for he did not attempt to retaliste, and his defence was of the feeblest. At last, approaching some scrub, he made a rush indicative of a forlorn hope, gained the shelter, and there remained. Mr. Kirk watched for fully half an hour, but he did not reappear. The sparrowa congregated in groups about the bushes, keeping up a constant chattering and noise, evidently on the look-out for the enemy, and congratulating themselves upon having secured a victory.

If we may judge from the Report of the Department of Agriculture, Victoria, for the year 1889-90, the farmers of that colony are likely to benefit largely by the work of the agricultural authorities. The Department is efficiently organized, and has a thoroughly scientific conceition of the nature of its duties. Mr D McAlpine, who has been appointed consulting vegetable pathologist, presents the following summary of the tasks undertaken by his particular section (1) special investigations concerning the rust of wheat, oats, barley, and other cereals, and, connected with that, the question of rust on various grasses-native and imported, (2) investigations of the life histories of the various fungus pests, and a knowledge of the best time to cope with them . (3) reports upon diseased specimens sent in from different parts of the colony, and the best known remedies for the palliation or prevention of such diseases . (4) collection of specimens of the various diseases due to fungi, and the subsequent formation of a museum for educational purposes. (5) delivery of lectures in different centres on the fungus pests most prevalent there . (6) preparation of illustrated handbooks, describing the nature of the various diseases and the remedies to be employed where possible, (7) testing various functiones and the best methods of applying them. (8) visiting different districts in order to find out prevailing and invisions fungi. (9) contributing periodic reports to the official Bulletin of the Department.

In the Proceedings of the Bath Natural History and Antiquaran Field Cab (ed. No. 19, M. J. F. Mostry, Clarke gives an account of the geological fornations exposed in the cuttings of the Bridgaueter Railway, the construction of which opened up a continuous line of eccavation through the heart of the Polden Hills Mr. Clarke had charge of the construction of the railway until near the completion of the earthwork, so that he had excellent opportunities for making careful observations. Geologists may be glad to have had description of the strats when the ologies of the cuttings are overground.

MESSRS LONGMANS, GREFN, AND CO have published the sixth edition of "An Elementary Treative on the Integral Calculus," by Dr Benjamin Williamson, F.R.S. In this edition the work has been revised and enlarged

MESSES. MITSCHER AND ROSEELL, 61a Jagerstrasse, Berlin, have issued an important list of books which they have for sale. The works relate to the various departments of botany

Two communications upon the volatile carbonyl compounds of platinum, from Dr. Pullinger, of Tubingen, and Drs. Mylius and Foerster, of Charlottenburg, appear in the last number of the Berichte Since the preparation of the remarkable carbonyl compounds of nickel and iron by Messey, Mond, Langer, and Quincke, these platinum compounds, discovered by Schutzenberger in the year 1868, have become more interesting, and the two papers now before us add considerably to our knowledge of They are compounds containing platinum, chlorine, and carbon monoxide, and Schutzenberger assigned to them the formulæ PtClaCO, PtCla 2CO, and 2PtCla 3CO respectively He obtained them by heating spongy platinum to a temperature of 250° C in a stream first of chlorine and afterwards of carbon monoxide The volatile, readily fusible, and crystalline sublimate obtained contained a mixture of the three, and he effected a separation by extraction with carbon tetrachloride, in which the three compounds are differently soluble. They are well defined by their melting-points, which are 194°, 142°, and 130° C respectively. They are decomposed by water with separation of plaunum, formation of hydrochloric acid, and evolution of carbon dioxide, and also, in case of the second and third compounds, of carbon monoxide. The most stable of these compounds and the best investigated is the simpler one, COPtCl. It appears to possess a distinctly basic character, so that it is able to combine with hydrochloric acid to form a compound, COPtCl_a HCl; this compound is formed in solution when the crystals are dissolved in concentrated hydrochloric acid The two other compounds are decomposed by hydrochloric acid, losing carbon monoxide and forming the hydrochloride of the first compound. On evaporation of

the hydrochloric solution, the first compound is left in needleshaped crystals. When phospene gas, COCL, is passed over the crystals, drops of liquid are formed, which consist of a solution of the compound in liquefied carbonyl chloride. In addition to these compounds, the bromide and todide corresponding to the compound COPtCl, have been prepared. When the hydrochloric acid solution of the latter is evaporated on a waterbath in a stream of hydrobromic acid gas, and the resulting compound extracted with benzene, the filtered solution deposits, on cooling, orange-red needles of the bromile, COPtBr. The bromide has likewise been obtained by Dr Pullinger, by passing carbon monoxide over heated platinous bromide Similarly, the iodide has been prepared by evaporating crystals of the chloride with excess of hydriodic acid solution, and treating the residue with warm benzene. The crystals of the sodide. COPtIa, which separate from the benzene solution on cooling, are deep red in colour, with a violet surface reflection. The chloride, bromide, and todide exhibit a beautifully graduated difference of properties Thus the chloride is vellow. the bromide orange, and the iodide red in colour. The meltingpoints are 194°, 181°, and 140° respectively. The chloride is readily, the bromide difficultly, and the iodide not at all volatile The chloride is strongly hygroscopic, the bromtde less so, and the jodide permanent. In addition to these compounds, another has been obtained by Dr. Pullinger, of the composition PtCl. 2COCl., in the form of non volatile vellow crystals. readily soluble in water, from which it recrystallizes unchanged, It appears to be the most stable of all these platinum compounds,

OUR ASTRONOMICAL COLUMN.

but is only obtained in very small quantity

INTURNICE OF ABERATION UPON OBSERVATIONS OF SOLAR PROVINENCES—Some recent observations of the development and movement of solar prominences have led M. Fizzar to consider the militare that the abertation of light may eserted the consideration of the properties of the consideration of the consideration of the consideration of the consequence of abertation, the longitude of the san, and therefore of the prominences, a diminished by the amount of the carth's orbital velocity. And it results from this that if a prominence is developed in the neighbourhood of the celliptic of the carth's orbital velocity. And it is results from this that if a prominence is developed in the neighbourhood of the celliptic of the carth's orbital velocity. And it is composed has a velocity and the luminous matter of which it is composed has a velocity postion will saffer a displacement of 20° 425, which may be dided to the effect due to the earth's motion, or otherwise, according to the direction of piopagation, and thus give rise to corresponding remainor with distance from the edge of the sun. Not the contraction of the c

Another point touched upon in the communication to which reference has been made is the physical nature of promin ences. The simplest hypothesis is that they represent clouds of incande-cent hydrogen and other metallic vapours, but Fizeau favours the idea that their visibility is the result of the passage of electrical discharges through gascous material.

NEW ASTEROIDS.—The 317th asteroid was discovered by Charlois on September 8, and the 318th on September 11

SOME OF THE POSSIBILITIES OF ECONOMIC BOTANY!

OUR Association demands of its President, on his retirement from office, some account of matters connected with the department of science in which he is engaged The subject which I have selected for the valedictory address

I he subject which I have selected for the valedictory address.

Association for the Presidential address delivered before the American Association for the Advancement of Science, as Washington, August 1891, by George Lincoln Goodale, M. D., L.D., Fisher Pr. fessor of Natural History, Harvard Unreversity, Cambridge, Mass., U.S.A.

deals with certain industrial, commercial, and economic questions revertheless it lies wholly within the domain of botany I invite you to examine with me some of the possibilities of economic botany

Of course, when treating a topic which is so largely speculative as this, it is difficult and unwise to draw a hard and fast line between possibilities and probabilities. Nowadays possi bilities are so often realized rapidly that they become accom-

Dished facts before we are aware.

In asking what are the possibilities that other plants the those we now use may be utilized we enter upon a many sided ask what plants the coming man will use?

There is an enormous disproportion between the total number of species of plants known to botanical science and the number of those which are employed by man

The species of flowering plants already described and named are about one hundred and seven thousand. Acquisitions from unexplored or imperfectly explored regions may increase the aggregate perhaps one-tenth, so that we are within very safe limits in taking the number of existing species to be somewhat

above one hundred and ten thousand Now if we should make a comprehensive list of all the flowering plants which are cultivated on what we may call a fairly large scale at the present day, placing therein all food and terry large scale at the present day, placing therein all lood and forage plants, all those which are grown for timber and calinet woods, for fibres and cordage, for timing materials, dye, reans, rubber, gums, oils, perfunes, and medicines, we could bring together barely three hundred species. If we should said to this short catalogue all the species, which, without cultivation can be used by man, we should find it considerably lengthened can be used by man, we should find it considerably lengthened A great inney products of the classes just referred to at cleaved in commerce from wild plants, but exactly how much their addition would extend the list. It is impossible in the present state, of knowledge to determine. Every enumeration of this character is I kely to contain a riots from two sources first, it would be sare to continue some species which have outlived them. real usefulness, and, secondly, owing to the chaotic condition of the literature of the subject, omissions would occur

But after all proper exclusions and additions have been made. the total number of species of flowering plants utilized to any considerable extent by man in his civilized state does not exceed,

In fact it does not quite reach, one per cent
The disproportion between the plants which are known and those which are used becomes much greater when we take into account the species of flowerless plants also. Of the five hundred ferns and their allies we employ for other than decotative purposes only five, the mosses and liverworts, roughly estimated at five hundred species, lave only four which are directly used by man. There are comparatively few Algæ, Fungi, or I ichens

man I nere are comparatively lew Alge, Fungi, of Telection which have extended use.

Therefore, when we take the flowering and flowerless together, the percentage of utilized plants falls far below the estimate made for the flowering alone.

Such a ratio between the number of species known and the number used justifies the inquiry which I have proposed for discussion at this time—namely, can the short list of useful plants be increased to advantage? If so, how?

This is a practical question, it is likewise a very old one one form of another, by one people or another, it has been asked from early times. In the dawn of civilization, mankind inherited from savage ancestors certain plants, which had been found amenable to simple cultivation and the products of these plants supplemented the spoils of the chase and of the sea. The pusses suppresented the spots of the chave and of life sea. The question which we ask now was asked then. Wild plants were examined for new users, primitive signiculture and noticultural extended their hounds in an-wer're this impury. Age fiver are has added slowly and cautomaly to the last of callurable and unlaable plants, but the aggregate additions have been, as we have seen, comparatively slight

The question has thus no charm of novelty, but it is as practical to day as in early ages. In fact, at the present time, in view of all the appliances at the command of modern science view of all the appliances at the command of motion science and under the strong light cut by recent biological and techno-logical research, the inquiry which we propose assumes great importance. One phase of it is belog attentively and vya tematically regarded in the great experiment stations, another phase is being studied in the laborations of disensity and pharmacy, while still another presents held in the unseems of conomic botune;

Our question may be put in other words, which are even more practical. What present likelihood is there that our tables may, one of these days, have other vegetables, fruits, and cereals, than those which we use now? What chance is there that new fibres may supplement or even replace those which we spin and weave, that woven fabrics may take on new vegetable colours. that flowers and leaves may yield new perfumes and flavours? What probability is there that new remedial agents may be found among plants neglected or new wholly unknown? The answer which I shall attempt is not in the nature of a prophecy, it can claim no rank higher than that of a reasonable conjecture

At the outset it must be said that synthetic chemistry has made and is making some exceedingly short cuts across this field of research, giving us artificial dyes, odours, flavours, and medicinal substances, of such excellence that it sometimes seems as if before long the old fishioned chemical processes in the there is no telling where the trumphs of chemical synthesis will there is no telling where the trimiphs of chemical synthesis will end, it is not probable that it will ever interfere essentially with certain classes of economic plants. It is impossible to conceive of a synthetic fibre or a synthetic fruit. Chemistry gives us fruit ethers and fruit acids, and after a while may progress us fruit ethers and vide us with a true artificial sugar and amorphous starch, but attificial fruits worth the eating or artificial fibres worth the spinning are not coming in our day

Spinning are not common and comments of synthetic chemistry. The synthetic between the content to accept, for a long time to come, the results of the intelligent labour of the cultivator of the cold and the explorer of the forest. Improvement of the good plants we now utilize, and the discovery of new ones, unit romain the core of large numbers of diffigurent students, and associations workned Su that, in fact, our question residies shirtly into the Can these controls are the controls of the control of the controls of the controls of the controls of the control of the controls of the controls of the control of the contro practical investigators hope to make any substantial advance? practical investigators nope to make any substitutial advance? It seems clear that, except in modern times, useful plants law leen selected almost wholly by chance, and it may well be said that a selection by accident is no selection at all. Nowadays, the new selections are based on analogy. One of the most syring illustrations of the modern method is afforded by the utilization of bamboo fibre for electric lamps

utilization of bamboo fibre for electric lamps. Some of the classes of useful plants must be passed by without pre-ent discussion, others alluded to slightly, while still other groups fairly representative of selection and improvement will be more fully described. In this latter class would naturally come, of course, the foo! plants known as

I THE CEREALS

Let us look first at these the species of grasses which yield these seed like fruits, or as we might call them for our purpose seeds, are numerous, twenty of them are cultivated largely in the Old World, but only six of them are likely to be very familiar to you—namely, wheat, rice, barley, oats, rye, and mare. The last of these is of American origin, despite doubts which have been east upon it It was not known in the Old World until after the discovery of It was not known in the Old World until after the discovery of the New It has prohably been very long in cultivation. The olders all belong to the Old World. Wheat and larley have been cultivated from the earliest times, according to Pc Candolle, the chief authority in these matters, about four thousand years. Later came yea and oas, both of which have been known in cultivation for at least two thousand years ocen shown in cuttivation for at reast two thousant years. Even the shorter of these periods gives time enough for wid-variation, and as is to be expected there are numerous varieties of them all. For instance, Vilmorin, in 1886, figured wasty inv variaties of wheat with plantly distinguishable characters of the Chance records are to be tristed, rice has been cut-

valed for a period much longer than that assigned by our history valed for a period much longer than that assigned by our history and traditions to the other cereals, and the varieties are correspondingly numerous. It is said that in Japan above three handred varieties are grown on irrigated lands, and more than one hundred on uplants.

With the possible exception of rice, not one of the species of

cereals is certainly known in the wild state

It is out of our power to predict how much time would clapse before satisfactory substitutes for our cereals could be elapse before satisfactory substitutes for our cereals could be found. In the improvement of the grains of grasses other than those which have been very long under cultivation, experiments have been few, scattered, and indective. Therefore we are as budly off for time sutors as ere the goologists and archeologists on their statements of elapsed periods. It is impossible for us to ignore the fact that there appear to be occasions in the life of a species when it seems to be peculiarly susceptible to the anduences of surroundings. A species, like a carefully laden and property in the seems of forces within and without Disturbance may come through variation from within, as from a shifting of the cargo, or in some cases from without. We may suppose both forces to be active in producing variation, may suppose outs forces to be active in producing variation, a change in the internal condition rendering the plant more susceptible to any change in its surroundings. Under the influence of any marked disturbance, a state of unstable equilibrium may be brought about, at which times the species as such

brium may be frought about, at which times the species as such sead upon by very high agencies as sea so consequent of cross breeding within the extreme limits of varieties. The resilization from its such cases on persist only by close breeding or by propagation from bank or the equivalents of bads. The remainst form in such cases on persist only by close breeding or by propagation from bank or the equivalents of bads. The manuter, groung a sport of various kinds. These critical periods, however, are not unwelcome, since skillal calitations can take propagation of the state of the st

done. Bat we must confess that it would be absolutely un-ossible to predict with certainty how long or how short would be the time before new cereals or acceptable equivalents for them would be provided. Upsteld by the confidence which I shave in the intelligence, ingentily, and energy of our experi-nance of the confidence of the confidence which I have in the intelligence, ingentily, and energy of our experi-anced that of two generations of our race, or half a century. In now laying saide our hypothetical illustration, I venture to alk why it is that our experiment stations, and other institutions dealing with plants and their improvement, do not undertake unretigations like those which I have sketched? Why are not reference to their adoption as food grains? One of these species will naturally suggest tieff to you all—namely, the widt rice of reference to their adoption as food grains ⁵ One of these species will naturally asagest itself to you all—namely, the wild rice of the lakes. Observations have shown that, were it not for the their control of the control of the

lines of least resistance, and are dusniclined to make a fresh start. It is merely leaving well enough alone, and so far as the cereals are concerned it is indeed well enough. The generous grains of modern in ceites of wheat and hearty compensation of the control of the contr

From the cereals we may turn to the interesting groups of plants comprised under the general term

II VEGETABLES.

Under this term it will be convenient for us to include all plants which are employed for culturary purposes, or for table use, such as salads and relishes.

The potato and sweet potato, the pumpkin and squash, the red or capsicum peppers, and the tomato, are of American

origin
All the others are, most probably, natives of the Old World.
Only one plant coming in this class has been derived from
Southern Australasia—namely, New Zealand spinach (Tetra-Among the vegetables and salad-plants longest in cultivation we may enumerate the following turnip, onion, cabbage, purslane, the large bean (Faba), chick-pea, lentil, and one species of pea (garden-pea). To these an antiquity of at least

4000 years is ascribed Next to these, in point of age, come the radish, carrot, beet, garlic, garden-cress, and celery, lettuce, asparagus, and the leek. Three or four leguminous seeds are to be placed in the same category, as are also the black peppers.

Of more recent introduction the most prominent are the parsnip, oyster-plant, parsley, artichoke, endive, and splnach.

From these lats I have purposely omitted a few which belong exclusively to the tropics, such as certain yams. The number of wareties of these vegetables is attounding. The number of wareties of these vegetables is attounding and the second of the second twenty, earrot more than thirty; beet, radish, and potato, more than forty. lettuce and onion more than fifty: turnip more than seventy, eabbage, kidney-bean, and garden pea,

The amount of horticultural work which these numbers represent is enormous. Each variety established as a race (that is, a variety which comes true to seed) has been evolved by the same sort of patient care and waiting which we have seen is necessary in the case of cereals, but the time of waiting

has not been as a general thing so long.

In the case of the cabbage there are important morphological changes like those to which Prof. Bailey has called attention in the case of the tomato Suppose we are strolling along the neach at some of the seasing resorts of trance, and anothe hall in with this coarse cruciferous plant, with its sprawling leaves and strong odour. Would there be anything in its appearance to lead us to search for its hidden merit as a food-plant? What could we see in it which would give it a preference over a score could we see in it which would give it a preference over a score of other plants at our feet? Again, suppose we are journeying in the high lands of Peru, and should meet with a strong-timeling plant of the nightshade family, bearing a small irregular fruit, of sub-acid taste and of peculiar flayour We will further fruit, of sub-acid taste and of peculiar navour we will surner magnic that the peculiar tastes strikes our fancey, and we conceive that the plant has possibilities as a source of food. We should be led by our knowledge of the potato, probably a nature of the same region, to think that this allied plant might be safely trans ferred to a nothern climate, but would there be promise of ferred to a northern climate, but would there be promise of enough future usefulnes, in such as case as this, to warrant our carrying the plant north as an article of food? Suppose, climber, we should secretain that the fruit in question was found awarrant our considerable and an article of the secretary and found favour among the tribes of South Mexico and Central America, and had been cultivated by them until that attained a large sare, should we be stronglened in our venture? Let the introduction of the plant, and having urged everybody to try it, we should find it discarded as a fruit, but taking a place in gardens as a consisty under an abard name, or as a basis for preserves and pickles, should we not look upon our experiment.

in the introduction of this new plant as a failure? This is not a hypothetical case plant in question, was cultivated in Europe, as long ago as 155¢; it was known in Virginia in 1785 and in the Northern States in 1785; but it found it way into favour slowly, even in this land of its origin. A credible witness eat or even tate of the fruit. And Yet, as you are well aware, eat or even tate of the fruit. And Yet, as you are well aware, are present cultivation on an enormous scale in Europe and this country is scarrely sufficient to met the increasing defeated.

country is carriery suincent to meet the increasing demand.

Before asking specifically in what direction we shall look for new vegetables. I must be pardoned for calling attention, in passing, to a very few of the many which are laredy in limited use in Europe and this country, but which ment a wider em-ployment Cardon, or eardoon; celeracy, or turnip-rooted celery; fettucus, or corn-alaid; martynia; salsify; sea-klaic; and numerous small alaids, are examples of neglected treasures.

of the vegetable garden.

The following, which are even less known, may be mentioned

Ine tollowing, wants are even to be a superior of the safety promising:—

(i) Aracaca exculenta, called Arracacha, belonging to the pariley family. It is extensively cultivated in some of the northern States of South America. The stems are swollen near

the hase, and produce tuberous enlargements filled with an ex-cellent starch. Although the plant is of comparatively easy cultivation, efforts to introduce it into Europe have not been successful, but it is said to have found favour in both the Indice,

and may prove useful in our Southern States.

(2) Ullucus or Ollucus, another tuberous-rooted plant from (2) Ouscuts or Outcome, another tuberous-roote man town nearly the same region, but belonging to the beet or spinach family. It has produced tubers of good size in England, but they are too waxy in consistence to dispute the place of the better tubers of the potato. The plant is worth investigating for our hot dry lands

for our bot dry lands'
(3) A table bearing relative of our common hedge settle, or
(3) A table bearing relative of our common hedge settle, or
France, for the Parts market. Its name in Parts is taken from
the locality where it is now grown for use. Although its native
country is Japan, it is called by some seedsmen Chrises art
and are rather beard to keep, but it is thought "that both of
these defects can be overcome or evaded." Experiments indsee that we shave in this species a wilsuble addition to our

We must next look at certain other neglected possibilities Dr Edward Palmer, whose energy as a collector and neuteness as an observer are known to you all, has brought together very interesting facts relative to the food-plants of our North American aborigines. Among the plants described by him there are a few which merit careful investigation. Against all of them, however, there he the objections mentioned before,

(1) The long time required for their improvement, and
(2) The difficulty of making them acceptable to the community,

volving
(3) The risk of total and mortifying failure
In 1844 the late Prof. Gray called attention to the remarkable relations which exist between the plants of Japan and those of our eastern coast. You will remember that he not only proved that the plants of the two regions had a common origin, but also emphasized the fact that many species of the two conntries are almost identical. It is to that country which has yielded us so many useful and heautiful plants that we turn for new vegetables to supplement our present food resources. One of these plants—namely, Stachys—has already been mentioned as promising There are others which are worth examination and perhaps

There are others which are worm assumes acquaration.

One of the most convenient places for a preisiminary extension of the vegetables of Japan is at the railroad nations on the longer lines—some there are prepared lanches on the longer three places are prepared lanches on boxes of two or three stories, provided with the simple and yet embarrassing chopsuicks. It is worth the shock at causes one's nerves to neven in these boxes and try the vegetable contents. The bits of fish, fissh, and fowl which one finds therein can be expected and discarded, upon which there will remain a few delicates. The personal proton of boiled rice is of excellent means. The generation portion of boiled rice is of excellent means. separated and discarred, upon water the set is that of aromatic vinegar. The pervading older of the box is that of aromatic vinegar. The generous portion of boiled ree is of excellent quality, with every gram well softened and distinct, and this without anything else would suffice for a total three were undifferent to the control of t boxes which have fallen under my observation there were sundry boiled roots, shoots, and seeds which were not recognizable by me in their cooked form Prof Georgeson, formerly of Jacoquarable by me in their cooked form Prof Georgeson, formerly of Jacoquarable by the cooking of the cooking of

greens of various kinds, dried cucumbers, and several kinds of seaweeds. Some of the leaves and roots are cooked in much the same manner as beet-roots and beet-leaves are by us, and the general effect in our unspeptings. The bouled shoots are suggestive of only the tougher ends of asparagns. On the whole, I do not look back on Japanese railway luncheous with any longing which would compel me to advocate the indiscriminate introduction of the constituent vegetables here.

But when the same vegetables are served in native finas, under more favourable culturary conditions, without the flavour of vinegar and of the pine wood of the lunchoon boxes, they appear to be worthy of a trial in our horticulture, and I therefore deal with one or two in greater detail.

Prof. Georgeson, whose advantages for acquiring a knowledge

of the useful plants of Japan have been unusually good, has placed me under great obligations by communicating certain facts regarding some of the more promising plants of Japan which are not now used here. It should be said that several of these plants have already attracted the notice of the Agricultural Department in this country

The soy hean (Glycine hispida) This species is known here to some extent, but we do not have the early and hest varieties. These beans replace meat in the diet of the common

people.
Mucuna (Mucuna capitala) and dolichos (Dolichos cultra-

tus) are pole beans possessing ment Diorectes There are several varieties with nalatable roots.

Posteria There are several varieties with passessing one of these was spoken of by the late Dr. Gray as possessing "excellent roots, if one could only dig them."

Colocaria antiquorum has tuberous roots, which are nutri

Conophallus Konjal has a large hulbous root, which is sliced, dried, and heaten to a powder. It is an incredient in Araha cordata is cultivated for the shoots, and used as we use

paragus. *Œnanthe stolonsfera* and *Cryptotanya canadensis* are palatable salad plants, the former being used also as greens.

III. FRUITS.

Botamcally speaking, the cereal grains of which we have spoken are true fruits—that is to say, are ripened ovanes, but for all practical purposes they may be regarded as seeds The fruits of which mention is now to be made are those com-

First of all, attention must be called to the extraordinary changes in the commercial relations of fruits by two direct

causes—
(1) The canning industry, and
(2) Swift transportation by steamers and railroads
The effects of these two agencies are too well known to
require more than this passing mention. By them the fruits require more than this passing mention. By them the fruits of the best fruit-growing countries are carried to distant lands in quantities which surprise all who see the statistics for the missance, the figures given by Mr. D. Morris, at the time of the great Colonia and Indian Exhibition in London. Compare double decades of pers—

In the Colonial Exhibition at London, in 1886, fruits from the remote colonies were exhibited under conditions which proved that, before long, it may be possible to place such deheacies as the cherimoyer, the sweet-cup, sweet-sop, ramdeheacies as the chemnoyer, the sweet-cup, sweet-sop, ram-buta, mange, and mangosteers, at even our most northern buta, mange, and mangosteers, at even our most northern crease in our knowledge with regard to the microbes which produce decay, we may be able to protect the delease fruits from injury for any reasonable period. Methods which will supplement refrigeration are sure to come in the very near suppresent refregation are sure to come in the formation and future, so that even in a country so vast as our own, the most perishable fruits will be transported through its length and breadth without harm

The canning industry and swift transportation are likely to diminish zeal in searching for new fruits, since, as we have seen in the case of the cereals, we are prone to move in lines of least resutance, and leave well enough alone

To what extent are our present fronts likely to be improved? Even those who have watched the improvement in the quality of some of our fruits, like oranges, can hardly realize how

of some of our frust, like oranges, can hardly realize how great has been the improvement within hattoric times in the chimeter of certain peans, against the continue of the part of the continue of the question. In the runs of the lake-dwellings of the continue of the c

In comparing the earlier descriptions of fruits with modern accounts, it is well to remember that the high standards by which fruits are now judged are of recent establish nent Fruits which would once have been esteemed excellent would to-day

which would once have been esterned excellent would to-day. It seems probable that the list of seedless frints will be materially lengthened, provided our experimental horiculturalist make use of the material at their command. The common apple, and certain oranges. Others mentioned by Mr Darwin as well known are the bread fruit, pomegnanie, arnaole or Neapoltan media; and date palms. In commenting upon these fruit, Mr, Darwin says that most horiculturatis "look at the great's use and anomalous development of the first as the cause, and sternity as the result," has the holds the opposite commentation of the commentation view as more probable—that is, that the steraity, coming about gradually, leaves free for other growth the aboundant supply of building material which the forming seed would otherwise have the admits, however, that "there is an antagonism between the two forms of reproduction, by seeds and by bads, when either is carried to an extreme degree, which is independent of any

incipient sterility."

Most plant-hybrids are relatively infertile, but by no mean wholly sterile With this sterlity there is generally augmented vegetative vigour, as shown by Nageli Partial or complete sterlity, and corresponding luxuriance of root, stem, leaves, and flower may come about in other obscure ways, and such cases are familiar to botanists. Now, it seems highly probable that, either by hybridizing directed to this special end, or by that, either by hymnianing an according this tendency to the correlated changes, we may succeed in obtaining important additions to our seedless or nearly seedless plants. Whether the ultimate lated changes, we may succeed, in obtaining important additions to our seedless or nearly seedless plants. Whether the ultimate profit would be large enough to pay for the time and labour involved is a question which we need not enter into, there appears to me no reaxonable doubt that such efforts would be appears to the no reason in the nature of things why we ahould not have strawberries without the so called seeds, blackberries and raspherries, with only delicious pulp, and large grapes as free from seeds as the small ones which we call "eurrants," but which are really grapes from Corinth.

"eurrants," but which are really grapes from Corinth.

These, and the coreless apples and pears of the future, the stoneless cherries and plums, like the common fruits beforestoneless cherries and pluins, like the co-minn truits netore-mentioned, must he propagated by bud division, and be open to the tendency to diminished strength said to be the con-sequence of continued had propagation. But this livridge need not be crossed until we come to it. Bananas have been perpetuated in this way for many centuries, and pineapples since the discovery of America, so that the borrowed trouble alluded

to is not threatening.

It is absolutely necessary to recollect that, in most cases, variations are slight. Dr. Masters and Mr. Darwin have called attention to this, and have adduced many illustrations, all of which show the necessity of extreme patience and caution general student curious in such matters can have hardly any task more instructive than the detection of the variations in such common plants as the blueberry, the wild cherry, or the like It is an excellent preparation for a practical study of the variations in our wild fruits suitable for selection

It was held by the late Dr Gray that the variations in nature by which species have been evolved were led along useful lines

—a view which Mr Darwin regretted he could not entertain However this may be, all acknowledge that, by the hand of the cultivator, variations can be led along useful lines, and, furthermore, the hand which selects must uphold them in their unequal strife. In other words, it is one thing to select a variety, and another to assist it in maintaining its hold upon evisience. Without the comitant help of the cultivator who selects the useful variety, there comes a reversion to the ordinary specific type

which is fitted to cope with its surroundings

I think you can agree with me that the prospect for new
fruits and for improvements in our established favourities is fairly good.

IV PINTERS AND CARINET WOODS

Can we look for new timbers and cabinet woods? Comparatively few of those in common use are of recent introduction. Attempts have been made to hring into great prominence some of the excellent trees of India and Australia which furnish wood of much beauty and timber of the best quality. A large pro-portion of all the timbers of the South Seas are characterized by remarkable firmness of texture and high specific gravity

same is noticed in many of the woods of the Indies
the heavier and denser sorts, like Jairah, of West Australia,
and Sabicu of the Caribbean Islands, have met with deserved
favour in England, but the cost of transportation millitate against them It is a fair question whether, in certain parts of our country, these trees, and others which can be utilized for our country, these trees, and others which can be utilized for veneers, may not be cultivated to advantage. Attention should be again called to the fact that many plants succeed far better in localities which are remote from their origin, but where they find conditions substantially like those which they have left, This fact, to which we must again refer in detail with regard to This fact, to which we must again refer in detail with regard to certain other classes of plants, may have some bearing upon the introduction of new timber trees. Certain drawhiseks exist hard-wood trees which have prevented their taking a high place in the scale of values in mechanical engineering. One of the most useful softwooded trees in the world is the

Kauri It is restricted in its range to a comparatively small area in the North Island of New Zealand It is now being cut down with a recklessness which is as produgal and shameful as that which has marked our own treatment of forests here. It should which has marked our own treatment of foreign free; it atout to be said, however, that this destruction is under protest; in spite of which it would seem to be a question of only a few years when the great Kauii groves of New Zealand will be a thing of the past. Our energetic Fored Department has on its hands

of the pass
problems just like this which perplexes one of the new lands of
the South The task in both cases is double to preserve the There is no department of economic botany more promising

in immediate results than that of arboriculture

V VEGETABLE FIBRES

The vegetable fibres known to commerce are either plant hairs, of which we take cotton as the type, or filaments of bast trissie, represented by flax No new plant hairs have been suggested which can compete in any way for spinning with those yelded by the species of Gossypium, or cotton, but experiments more or less systematic and thorough are being carried on with regard to the improvement of the varieties of the species Plant hairs for the stuffing of cushious and pillows need not be referred to in connection with this subject
Countless sorts of plants have been suggested as sources of

good bast fibres for spinning and for cordage, and many of these make capital subtitutes for those already in the factories. But the questions of cheapness of production, and of subsequent preparation for use, have thus far militated against success. There may be much difference between the profits promised by a laboratory experiment and those resulting from the same pro-cess conducted on a commercial scale. The existence of such

differences has been the rock on which many enterprises seeking to introduce new fibres have been wrecked

In dismissing this portion of our subject it may be said that a process for separating fine fibres from undesirable structural ele-ments and from resin-like substances which accompany them is a great desideratum. If this were supplied, many new species would assume great prominence at once

VI TANNING MATERIALS.

What new tanning materials can be confidently ought for? In his "U-full Nature Plants of American," Mr. Maden about half as many eucalyter, which have been examined for the amount of tanning material contained in the bark. In all, eighty sever Autralian apecies have been under examination Brailer thin, much has been done looking in the same direction of the most and another the detection of Planton on Meeller, at the suggestion and smooth the detection of Planton on Meeller, at the suggestion and under the direction of Baron von Auseier, of Victoria This serves to indicate how great is the interest in this subject, and how wide is the field in our own country for the introduction of new teaming plants.

It seems highly probable, however, that artificial tanning substances will at no distant day replace the crude matters now

employed

VII RESINS, &c.

Resins, oils, gums, and medicines from the vegetable kingdom Keuns, oils, gums, and medicines from the vegetable kingdom would next engage our attention if they did not seem rather too technical for this occasion, and to possess an interest on the whole somewhat too limited. But an allied substance may serve to represent this class of products and indicate the drift of present research

India Rubber - Under this term are included numerous sub-

stances which possess a physical and chemical resemblance to eich other. An Indian Freus, the early source of supply, soon became inadequate to furnish the quantity used in the aris even when the manipulation of rubher was almost unknown. Liter supplies came from Meroe of Brain, generally known as Pian rubber, and from Castifos, sometimes called Central American rubber, and one Manish of Menanis, Cenar rubber. Not only are these plants now successfully cultivated in experimental gardens in the tropics, but many other rubber-yielding species have been added to the list. The Landolphias are among the most promising of the whole these are the African rubbers Now in addition to these, which are the chief source of supply. we have Willughbera, from the Malayan Peninsula, Lemonotis, (hilocarpus, Alstonia, Forsteronia, and a species of a genus formerly known as Urostigma, but now united with Figure These names, which have little significance as they are here pro nounced in passing, are given now merely to impress upon our minds the fact that the sources of a single commercial article may be exceedingly diverse. Under these circumstances search is being made not only for the hest varieties of these species but for new species as well

There are few excursions in the tropics which possess greater interest to a botanist who cares for the industrial aspects of and at Singapore. At both these stations the experimental gardens lie at some distance from the great Cardens which the tourist is expected to visit, but the exertion well repays him for Under the almost vertical rays of the sun, are all discomfort here gathered the rubber-yielding plants from different countries, all growing under conditions favourable for decisions as to their telative value. At Buitcizorg a well equipped laboratory stands ready to answer practical questions as to quality and composition

of their products, and year by year the search extends
I mention this not as an isolated example of what is being I mention this, not as an isolated example of what is being accomplished in commercial botany, but as a fair illustration of the thoroughness with which the problems are being attacked it should be further stated that at the Garden in question assidious students of the subject are eagerly welcomed, and are provided with all needed appliances for carrying on technical, chemical, and pharmaceutical investigations. Therefore I am chemical, and pharmaceutical investigations. Therefore I am justified in supring that there is every reason for believing that in the very near future new sources of our most important products. will be opened up, and new areas placed under successful cultivation

CHITMATON At this point, attention must be called to a very modest and convenient liand-hook on the "Commercial Budany of the Ninchestal Centry," by Mr Jackson, of the Botanical Misseum attached to the Royal Gradens, Kee, which not only embodies a great amount of well arranged information relative to the new useful plants, but is, at the same time, a record of the exising state of things in all these departments of activity

VIII. FRAGRANT PLANTS

Another illustration of our subject might be drawn from a class of plants which repnys close study from a biological point of view—namely, those which yield perfumes In speaking of the future of our fragrant plants we must dis

tinguish between those of commercial value and those of purely horticultural interest. The former will be less and less cultivated in proportion as synthetic chemistry by its manufacture of per-fumes replaces the natural by the artificial products, for example, coumarin, vanillin, nerolin, heliotropin, and even oil of winter-

When, however, one has seen that the aromatic plants of Australia are almost free from attacks of insects and fungi, and Australia are atmost free from attacks of insects and fungi, and has learned to look on the impregnating substances in some cases as protective against predatory insects and small foes of all kinds, and in others as fungicidal, he is tempted to ask whether all the substances of marked odour which we find in certain groups

all the substances of marked ofour which we find in certain groups of plants may not play a similar roll.

It is a fact of great interest to the surgeon that in many plants there is associated with the fragrant principle a marked antiseptic or fungicidal quality; conspicuous examples of this are afforded by ancers of European, welding realization. Stream, welding by species of Eucalypius, yielding eucalyptol, Styraa, yielding styrone, Thymus, yielding thymol It is interesting to note, too, that some of these most modern antiseptics were important constituents in the balsamic vulneraries of the earliest surgery Florists' plants and the floral fashions of the future constitute

an engaging subject, which we can touch only lightly. It is reasonably clear that while the old favourite species will hold

their ground in the gaire of improved varieties, the new introtheir ground in the gaire of improved varieties, the new mitro-ductions will come in the shape of plants with flowering branches are proposed to the proposed of the proposed plants and especially those in which the flowers precede the lenves. In short, the next real fashion in our gardens is probably to be the flowering shrub and flowering tree, like those which are such flowering the proposed plants are proposed to the country from which the Western would has cladly taken the gift of the chrysanthemum

Twice each year, of late, a reception has been held by the Emperor and Empress of Japan. The receptions are in autumn and in the spring. That in the autumn, popularly known as the Emperor's reception, has for its floral decorations the myrind forms of the national flower, the chrysanthemum, that which is given in spring, the Empress's reception, comes when the cherry bissions are at their best. One has little idea of the wealth of beauty in masses of flowering shrubs and trees, until he has seen the floral displays in the Imperial Gardens and the Femple. grounds in l'okio

CONCLUSION

Lack of time tenders it impossible to deal with the questions which attach themselves to our main question, especially as to which attach themselves to our main question, especially as to the limits of effect which cultivation may produce. We cannot touch the problem of inheritance of acquired peculiarities, or the manner in which cultivation predisposes the plant to innumer-able modifications. Two of these modifications may be mentioned in passing, because they serve to exemplify the practical character of our subject.

Cultivation brings about in plants very curious morphological changes. For example, in the case of a well known vere table the number of metamorphosed type leaves forming the ovary is two, and yet under cultivation the number increases irregularly until the full number of units in the type of the flower is reached Prof Bailey, of Cornell, has called attention to some further interesting changes in the tomato, but the one mentioned suffices to illustrate the direction of variation which plants under suffices to illustrate the direction of variation which plants under cultivation are given to take. Mostiventures are very at to occur equivalent to the control of the con

We have now arrived at the most practical question of all. namely-In what way can the range of commercial botany be extended?

In what minner, or by what means, can the introduction of new species be hastened? It is possible that some of you are aware of the great amount of uncoordinated work which has been done and is now in hand

in the direction of hringing in new plants The competition between the importers of new plants is so great both in the Old World and the New that a very large proportion of the species which would naturally commend themselves for the use of florists, for the adornment of greenliouses, or for commercial ends, have been at one time or another

brought before the public or are being accumulated in stock brought bufore the public or are being accumulated in stock. I he same as true, although to a less extent, with regard to useful as the same of the same of the same of the same of the as desirable for trail has not already been investigated as chemical, pharmaceutical, medical, horticultural, agricultural and trafe journals, especially those of high grade, contain a wealth of material of this character. But what is needed is they that the promising plants should the same of the But what is needed is they that the promising plants should

But what is needed in they that the promising plants should be systematically investigated under exhaustive conditions. It is not enough that an enthusiast kere, or an amateur there, should give a plant a trail under imperfactly understood conditions, and then report success or failure. The work should be thorough, and every question nonswerted tactgeorically, so that we might be placed in po-sevenon of all the facts relative to the object experimented upon. But such an undertaking require object experimented upon. But such an undertaking requires the co operation of many different agencies. I shall venture to cution some of these

mention some of these In the first place, Botanic Gardens amply endowed for research The Arnold Arboretum, the Shaw Garden, and the Washhigton Experimental Garden, are American illustrations of what is needed for this purpose. University gardens have their place in instruction, but cannot wisely undertake this kind of work.

In the second place, Museums and Laboratories of Zo-nomic Botary. Much good work in this direction has been department in charge of the investigation of new plants. We need institutions like those at Kew in England, and at Bulerancer in Java, which keep in close touch with all the nitude commensurate with the greatness and needs of our country is an undertaking which wait for some one of our

In the third place, Experiment Stations. These may, within the proper limits of their sphere of action, extend the study of plants beyond the established varieties to the species. study of plants beyond the established varieties to the species, and beyond the species to equivalent species in other genera. It is a matter of regret that so much of the energy displayed in these stations in this country, and we may say abroad, has not been more economically directed.

Great economy of energy must result from the recent change by which co-ordination of action is assured. The influence which the sintions must exert on the welfare of our country and

the development of 118 resources 18 incalculable In the last place, but by no means least, the co-operation of all who are interested in scientific matters, through their obser-vation of isolated and associated phenomena connected with plants of supposed utility, and by the cultivation of such plants by private individuals, unconnected with any State, Governmental, or academic institutions

By these agencies, wisely directed and energetically employed, the domains of commercial and industrial botany will be en-arged. To some of the possible results in these domains. I have endeavoured to call your attention.

THURSDAY, OCTOBER 8, 1801.

THE ICE AGE IN NORTH AMERICA.

The Ice Age in North America, and its Bearings upon the Antiquity of Man By G Frederick Wright, D D, &c. With an Appendix on "The Probable Cause of Glaciation," by Warren Upham, F.G S A. With many new Maps and Illustrations. (London: Kegan Paul, Trench, Trubner, and Co, Limited, 1890)

SWITZERLAND has been called the playground of Europe The glacial epoch occupies a similar position in geology. Here the student, weared with the precision of palicentology or of mineralogy, may revel in dreams of omnipotent glaciers, wrap himself in ice sheets, throw mental somersaults, swallow self-contradictory arguments, and be as blind to unpleasant facts as was nelson at Copenhagen, when he put the telescope to his useless eye, and "spoke disrespectfully" of the signal of recall. To any sucrestic hioran of the progress of recall. To any sucrestic hioran of the progress of abone, since it is so rich in unsound inductions and unsable hypothesis.

Dr. Wright's book, however, is, on the whole, a favourable exception to this general rule Passages, no doubt, may be found here and there, to which exception might be taken—notably to his remarks on the subject of cirques, in which he regards with favour opinions which are hard to reconcile with expressions in other parts of the book, and rest largely on an erroneous statement and "as a rule... occupy positions where glaciers first and "as a rule... occupy positions where glaciers first by facts, very clearly and carefully described, so that we feel, even if occasionally not quite convinced, that his view is worthy of careful and respectful consideration.

But in the matter of ice the subject is long, and our space is brief It will be better to abstain from criticism of details and give a short outline of those parts of Dr. Wright's book which will be of most interest to readers on this side of the Atlantic. As he states in his preface, his work deals not only with the Ice Age in North America, but also with the whole subject of the Glacial Period. So in its earlier part a considerable space is allotted to glaciers in general and their characteristics; in its later, so the the effects of the Glacial Period. In the subject of the Glacial Period in other parts of the world, its cause, its date, and its relation to the history of man. These, however, we shall pass over, and confine ourselves to the section dealing with glacial action on the North American continent.

After a sketch of the existing glaciers on the Pacific coast, Dr. Wright gives the results of a study of the Mur glacier in latitude 56° 50′, by the side of which a small party, of which he was a member, camped out for a month. This glacier is about a mile wide where it comes down to the sea, terminating in rec cliffs 300 feet, and sometimes a little above 400 feet in height. The rise in-land is gradual—perhaps about 100 feet per mile—and the main body of the glacier occupies a wast amphilithease, with diameters ranging from 30 to 40 miles. From a number of observations it appeared that the stream of ice entered the inlet, where the cross section

was about five milton square feet (5000 feet wide by 1000 deep), at an average rate of 40 feet a day (70 feet in the centre and to near the margin). It was, however, evident that this glacier, for some time past, had been reteating; indeed, fresh strations and dibbra could be traced to more than 2500 feet above its present surface. Dr Wright also found below the end of the ice the dead stumps of a forest of cedar trees, erect, and rooted in a clayey soil, but buried beneath glacial gravel. Probably this was deposited by streams, flowing from the advancing ice, wifich afterwards overrode the mass.

Dr. Wright estimates the amount of sediment which is now being washed down from the basin of the Muir Glacier as equal to nearly one-third of an inch per annum over the total area (1200 square miles) which it occupies. In regard to the vexed question of the excavatory powers of glaciers, Dr Wright expresses himself, as a rule, cautiously, ascribing to them the formation of true rockbasins under favourable circumstances, but laving stress upon the fact that, in the lower part of their course, where they are beginning to spread out over the lowlands, they can pass, as in the case mentioned above, over quite incoherent materials, without disturbing them. It also seems to follow from his remarks that he regards glaciers as agents of abrasion rather than of erosion, in which we have no doubt he is correct. As another indication of his general caution and candour, we may note that he is careful to point out that striated stones and rock surfaces do not always prove the former presence of a glacier, and may not even have been produced by the action of ice.

A large part of the book is devoted, as a matter of course, to a description of the glaciated area in North America. The boundary of this, as Dr Wright explains. is sometimes distinctly marked by a terminal morains, at others it is less definite, being only vaguely indicated by scattered dibris. But in his opinion-and here he expresses the opinion of the majority of American geologists-there was a time when a large part of Northern America east of the Rocky Mountains was buried beneath a mass of ice. There is, indeed, a driftless area in Wisconsin, which may have formed a kind of jardin on a gigantic scale, in this huge mer de glace, but, speakmg generally, the whole region of the great lakes was covered by an ice-sheet which came down to the sea at Long Island and traversed the northern part of Pennsylvania; thence its irregular frontal margin can be traced to the south-west, until, in the valley of the Mississippi, it reaches almost as far south as the 37th parallel of latitude. Of the various indications of this vanished ice-sheet, the smoothed and striated surfaces of rock, the moraines and boulder clays, the "kames" and "drumlins," Dr. Wright gives careful descriptions and illustrations, usually taken from photographs, so that the evidence is presented as clearly as is possible to the reader. To the last-named phenomena-the "kames" and "drumlins"-and some curious hollows which he calls "kettle-holes," Dr. Wright devotes much attention. The first he regards as indicative of lines of drainage in the closing stage of the Ice Age; the second, as early taminal moraines, modified in shape by the subsequent passage of the ice over them, and so anterior in date to the kames The kettle holes occur among moranic deposits, and are thus explained :- As the

ice is retreating, a mass of it may be insulated; as this melts, the superincumbent material tends to slip towards the edges, and thus to form a ring of debris, by which, after the ice has disappeared, a hollow is inclosed. Dr. Wright also adopts the opinion, maintained by Prof. Claypole, the late Prof. H. C. Lewis, and others, that one effect of the advance of this great mass of ice was to obstruct the flow of all rivers which take a northerly course, and thus to convert their valleys into lakes.

But into a discussion of this interesting question, and of the cause of the glacial epoch, to which a considerable space is devoted, we must not now enter. We must also pass over the questions relating to the date of the glacial epoch and its relation to the first appearance of men, merely stating that Dr. Wright inclines to regard the latter as pre-glacial, but the former as less remote than is generally supposed. It must suffice to say that he appears to be a careful observer, and generally a cautious reasoner, though slightly too prone to quote the remarks of others without due criticism , so that, on the whole, his book presents us with a good summary of the results of investigations into the glacial geology of North America, and will be valuable for purposes of reference on this side of the Atlantic. T G BONNEY.

THE TOTAL REFLECTOMETER AND THE REFRACTOMETER FOR CHEMISTS.

Das Totalreflectometer und das Refractometer fur Chemiker, ihre Verwendung in der Krystalloptik und zur Untersuchung der Lichtbrechung von Flussigkeiten. Von Dr. C. Pulfrich, Privatdocenten an der Universität Bonn, und Assistenten des physikalischen Instituts. With a Lithographic Plates and as Figures in the Text (Leipzig · W Engelmann, 1890)

"HIS book contains an exhaustive account of one of the latest devices in physical optics for investigating the refractive power of uniaxial and biaxial crystals. The idea of making use of the principle of total reflection for this purpose is not new Wollaston, at the beginning of the century, brought forward a method in which the crystal plate under examination was attached to a glass prism : but, owing to the experimental difficulties involved in this process, it met with little practical application, The instrument constructed by Kohlrausch in 1878, in which the crystal plate was immersed in a strongly refractive liquid, was a distinct advance, and has been much used. Within the last ten years, also, Wollaston's apparatus has been considerably improved by Fussner and Liebisch. Both these instruments, however, have still many inconveniences, and it is the claim of the author that the method which he has devised, and which forms the subject of the present work, is free from these,

To give some idea of this method, without entering into practical details, it will be sufficient to state that it consists essentially in the replacement of the prism of the Wollaston instrument by a glass cylinder, to the upper plane surface of which the crystal plate is attached. The cylinder can be rotated about its long axis, so that the refractive phenomena in all azimuths can be observed. This is the distinguishing feature which forms the chief advantage of

from the side at grazing incidence, and slowly rotating the cylinder, the whole extent of the limiting curves of total reflection comes under observation. By a special method of illumination from all sides the limiting curves may be received on a screen beneath the cylinder and made visible to a number of observers; e.g. in the case of a uniaxial crystal the appearance on the screen will be the sectional curves of the wave-surface, a circle and an ellipse corresponding to the ordinary and extraordinary rays.

The method was first suggested by the author four years ago. The object of the present work is to give a complete account of the series of measurements and observations which have been made with the instrument since that time with a view to testing its usefulness and trustworthiness After some preliminary observations on the theoretical principles involved in the method of total reflection, the author gives a detailed description of the construction of the new instrument and the methods of observation by which it is possible in a single crystal section to ascertain the position of the axes of elasticity, to measure the optic axlal angle for different colours, and to determine the principal refractive indices. Of special interest is the section on the appearances in the direction of the optic axes of biaxial crystals Observations made on a plate of asparagine, cut parallel to the optic axial plane, showed distinctly the effects due to the internal and external conical refraction, thus supplementing Lloyd's experiments in demonstrating the general correctness of the Fresnel wave-surface. The last section of the book deals with the refraction of liquids, and contains a description of the refractometer for chemists, which is a simplified form of the total reflectometer, in which a prism replaces the cylinder. Altogether, a perusal of the work leaves the impression that the invention of this ingenious and yet comparatively simple method for investigating the refractive power of doubly refractive media marks a decided advance in physical science, and the author appears to have quite substantiated his claim to have made the total reflection method, which has long been recognized as theoretically the most promising, also a thoroughly practical one. G, T, P.

A WEATHER RECORD OF THE FOURTEENTH CENTURY.

Consideraciones temperies pro 7 annis, per Magistrem Wilhelmum Merle, socium domus de Merton. Reproduced and Translated under the supervision of G. J. Symons, F R.S (London, Edward Stanford, 1801.)

N January 1337, barely forty-five years after the death of Roger Bacon, and ten years after the accession of King Edward the Third, William Merle, a Fellow of Merton College, and Rector of Driby, in Lincolnshire, commenced a journal of the current weather as expersenced partly at his rectory "in Lyndesay, near the north-east coast," and partly at Oxford. This journal he continued month by month for seven years, or up to three years before his death, the notices of the last four years being considerably amplified over the earlier entries; and the original manuscript, still preserved in the Bodthe new method. Thus, by illuminating the crystal plate | lean Library, has now, thanks to the initiation of Mr. G. J. Symons, been reproduced in factimile by photography, translated from the monkish Latin of the original text by Miss Parker, and published in a handsome small folio volume, of which one hundred copies have been printed. It is probably, as stated on the title-page, the earliest known weather journal in the world.

The manuscript consists of nine and a half pages of abbreviated Latin, written on vellum in a distinct and easily decipherable text, and is apparently in excellent preservation. It is bound up with a number of other manuscript treatises (one of which is also by Merle) dealing with weather prognostication, astrological lore, and other subjects which, according to the scientific views of the day, were nearly related branches of knowledge. Some of these treatises were collected, and some written by, William Reed, who was Bishop of Chichester from 1369 to 1386, and who bequeathed them to scholars of Merton, "being of his kin" Subsequently, the volume passed into the possession of Sir Kenclin Digby, who, in 1634, presented it, together with other manuscripts, to the Bodleian Library It is interesting and not uninstructive to note how modest a figure is cut, in this scientific record of the fourteenth century, by the few pages of original observation amid the mass of speculative writings in which they are buried, and how in the nineteenth century they alone retain all their pristine value, and are resuscitated with all the honours of facsimile reproduction, while the learned treatises on the conjunctions of the planets, the lunar mansions, and rules for prognosticating the weather, are left undisturbed in the musty dignity in which they have reposed for more than five centuries.

As already remarked, Merle's entries are at first very brief, the notice of each month's weather seldom exceeding two lines of the manuscript Thus for January 1337 we find :-

"In January there was warmth with moderate dryness, and in the previous winter for the previous part of the same winter?] there had not been any considerable cold or humidity, but more dryness and warmth "

Gradually, however, the notes expand, and it is not a little interesting to trace how by degrees the journalist's growing interest in his probably novel undertaking leads him to record more and more in detail the facts that present themselves to his daily observation. Thus from a brief general summary of the characteristic weather of the month, as illustrated in the above quotation, at the end of the year he proceeds to record the character of each week, and towards the end of the third year (1339) he begins to notice the weather of a few special days. From the beginning of 1340 greater amplification is indulged in : the monthly notes often expand to six or eight lines, and in the final year of the record (1343) sometimes to from ten to fourteen lines. In illustration of these more detailed entries, the notice for July 1343 may be

"July.—Considerable heat on the first five days, and it was great on the 3rd and 4th. On the 4th, two or three hours before sunset, heavy thunder began with more vivid lightning than I think I had ever seen, which lasted until mid-night, with heavy rain. 5th, light thunder about sunset. On the 6th day and throughout the second week it was

gloomy, and there was a slight fog occasionally. 12th, light rain, 14th, gloomy, 15th, and three following days, considerable heat, 19th, rain which penetrated a good deal: 20th, light rain, 22nd, rain: 25th, heavy rain, with deary thunder in the night, and also in the morning of the following day. All the remainder was rainy, with fog, and rain in small drops, and it was gloony the whole time, 28th in the night, and 29th in the morning, thunder, with heavy rain thunderstorms" There was lightning with the last two

For the last four years, indeed, Merle's notes are sufficiently ample to allow of a fair estimate of the weather of those years in comparison with that of the present day, and perhaps some such comparison may be instituted by those who have at command the ample registers of our own time for the same part of Lincolnshire Seeing how great have been the changes wrought in the character of the surface of the country, by the clearing of forests, dramage, and the extension of agriculture, such a comparison may possibly furnish matter of great interest

The fourteenth century is sadly memorable for the disastrous famines and pestilences that then desolated England, and above all for the "Black Death," which half depopulated the realm, and was nowhere more fatal than in East Anglia But this last did not make its first appearance until the end of 1348, about a year after Merle's death, and nearly five years after the conclusion of his journal, which ends abruptly with January 1344. and although a severe famine is recorded in 1335, and another in 1353, it does not appear that any of the years included in his register was especially disastrous. The famine of 1335 is said to have been due to excessive rain. and we may perhaps harard the surmise that the recent memory of this visitation was the stimulus that induced Merle to record these interesting notes, which good fortune has preserved for us through five and a half confuries

OUR BOOK SHELE.

The South Italian Volcanoes. Being the Account of an Excursion to them made by English and other Geologists in 1889, under the auspices of the Geologists' Association of London, with Papers on the Different Localities by Messrs Johnston-Lavis, Platania, Sambon, Zezi, and Madame Antonia Lavis, including the Bibliography of the Volcanic Districts, and Sixteen Plates. Edited by H J. Johnston-Lavis, M.D., F.G.S., &c. Pp. 342 (Naples: F. Furchheim, 1891.)

In this useful volume, Dr. Johnston-Lavis has issued reprints of his report on the Italian excursion made by the members of the Geologists' Association under his direction, and of his abridged sketch of the geology of Vesuvius and Monte Somma, already noticed in this journal. These reprints are accompanied by several journal. These reprints are accompanied by several interesting original papers—annely, one on the thermomeral and gas springs of Sujo, near Roccamonias, by Polyndamon. Laws himself; one on the geology of Acrashabe Polyndamon. Polyndamon and Polyndamon and Acque Abbule in the neighbourhood of Tivoli, *by Signor Pietro Carlon, *control of the Polyndamon and Acque Abbule in the neighbourhood of Tivoli, *by Signor Pietro Carlon, *control of Pietro Pietro (Pietro) and Acque Abbule in the neighbourhood of Tivoli, *by Signor Pietro (Pietro) and Pietro (Pietro) and Acque Abbule in the neighbourhood of Tivoli, *by Signor Pietro (Pietro) and Pietro (Pietro) and Acque Abbule in the neighbourhood of Tivoli, *by Signor Pietro (Pietro) and Pietro (Pietro) and Acque Abbule (Pietro) and Acque Abbule (Pietro) and Acque Abbule (Pietro) and Acque Abbule (Pietro) and Pietro) and Pietro (Pietro) and Pietro) and Pietro) and Pietro) and Pietro (Pietro) and Pietro) and Pietro) and Pietro (Pietro) and Pietro) and Pietro

well-selected points of view, and admirably reproduced as well-selected points of view, and admiratily reproducest as small quarto plates. These plates are striking illustrations of what can be accomplished by instantaneous photography as an aid to sulcanological study. Among them are very instructive views of explosive outbursts from the creaters of Stromboli and Vulcano. In the case of the small explosions from the first-mentioned volcano, the ejected fragments are seen in the midst of the steamclouds; and in the case of the more violent eruptions from Vulcano several phases in the same outburst have been know this very interesting district will be glad to have their recollections revived by these admirable plates; and those who have never had the pleasure of visiting the South Italian volcanoes may obtain from these remarkable photographs a much better idea of the localities than any descriptions or drawings can possibly give.

Buried Cities and Bible Countries. By George St. Clair, F.G.S. (London: Kegan Paul, Trench, Trubner, and Co. 1801)

EVERYONE knows that recent archæological research has brought to light a vast number of facts which are directly or indirectly connected with ancient Hebrew The object of the author of the present work is to set forth the more important of these facts, and to explain their significance. He deals with the results of explain their significance. He deais with me results or exploration in Egypt, Palestine, and Mesopotamia; and he has a chapter on Jerusalem, with legard to the topo-graphy of which he has been led to conclusions different from those of other writers. The book has been prepared for the benefit of persons "who have no time to follow the course of exploration, and no taste for technical details". and readers of this class will find in technical details", and readers of this class will find in it much that will be to them both new and interesting. The value of the text is increased by good maps, plans, and other illustrations

Food, Physiology, &c By William Durham, F.R.S.E. (London and Edinburgh A. and C. Black, 1891)

THIS is the third volume of a series by Mr Durham, entitled "Science in Plain Language." The author does entitled "Science in Plain Language." The author does not pretend to say anything new, but he has brought together, and arranged clearly, a mass of facts which will no doubt be of interest, and may be of practical service, to many readers who have neither time nor service, to the total property of the consideration of solid and liquid foods. then gives some account of the constituents of food, and finally sketches the structure and functions of the bodily organs.

Blackie's Science Readers (London: Blackie and Son.

THE aim of this series is to arouse the interest of children in the common objects of the natural world, and to give in the common objects of the processes by which articles of ordinary use are produced. The idea is excellent, and has been very successfully worked out. The series consists of five little volumes, the first two of which present some "lessons on common objects" From the third volume. the reader wiff learn something about the simple principles of classification; about substances used in arts and manufactures; about phenomena of earth and atmosphere; and about matter in three states—solids, liquids, and gases. The fourth and fifth volumes—by the Rev. Theodore Wood—deal with animal and plant life. The facts set forth have been carefully selected, and they are presented in a bright, easy, natural style which cannot fail to make them at once intelligible and attractive. Good teachers will find the series of real service in helping them to foster in the minds of their pupils a love of accurate observation and independent reasoning

Comparative Palatability

Wilst the view of supplementing the experiments carried out last year by Mr. F. Finn said myself (NATURE, vol. 3kii, pp. research of the common frequent of the description, research of the common frequent of the common frequent of the Markov (Markov). The common frequent of the Markov (Markov) is the control of a Inplantual Genous and workers, have recorded to J. Anjudersus (Genous and workers), and muscrasm (Grones and workers), from the common only a freely-frequent greg related to attack for one occasion only a freely-frequent greg related to attack for On one occasion only a freely-feeding frog refused to attack for the second time a large queen of ierretire, which had sting its mouth. Many of the insects were, however, thus taken at the second attempt. The common warp was eaten eagerly by frogs and toads. I was again unfortunate in not taking any Chrystades. Surver, grays was attacked both by a frog, for which it seemed to large, and by a toad, under whose lip it appeared to insert its ovipositor. Neither animal ventured to seize it again—certainly for an hour or so I was then obliged to abandon the observa-

composition. Nettner animal wentured to test it again—certainly composition. It could get not have sheen successful to a constraint of the control of the co

Blatta orientals: was taken without hesitation, as week, of course, earthword observation, only one was of much work-ing value. This specimes (a male) became in a fortinght to include the property of the property of the property of which I placed the insects, &c., in the inclosure. The fact re-calls Mr. E. B Poulton's observation, that his tree-frog seried the end of the forceps with which food was given them. It is, perhaps, worthy of arotice that the larve of the blow-fly, though eaten ergerly by toads, are frequently passed whole from the lody; and would, therefore, seem to be with difficulty

digested.

Want of time has prevented my experimenting, as I had wished to do, with Salamandra maculosa. Mr. F. Finn offered a specimen to ducks, which will eat the small newt, and found that though more than one bird observed it, and one even ran towards it, it was not touched. The observation extended over more than an hour.

NO. 1145, VOL. 447

Occurrence of the Ringed Snake in the Sea.

THE readiness with which the British snake (Tropidonotus natrix) will enter fresh water is well known. Its occurrence in the sea seems anomalous, and therefore I venture to submit the following details.

tollowing details.

The specimen in question was seen on September 7, from a small boat on the east coast of the Isle of Wight, while about a thousand yards distant from the shore, and about midway between Shanklin and Luccombe Chines. When first seen it was swimming straight out to sea—viz in an easterly direction.

The sea was calm and a strong current was flowing from the south, so that the creature was swimming across the current.

At first it took no notice of the hoat, but as the boat was rowed towards it, it changed its course and swam directly away from the bas. It was foot experience, and found to be uniqued and most conductor. Upod discount of the uniqued and most conductor. Upod discount of the entire alimentary cand was absolutely empty. The internal 31 inches in length. It is most probable that this snake entered the sea shout a find from where twas obtained, as the beach is bounded by almost perpendicular cliffs, some 30 of eet high, at that place. the boat. It was soon captured, and found to be unnitured and

The Heights of Auroras.

The Heights of Auroras.

Tits rare part of the phenomena described by your correspondents is the extreme narrowness of the auroral strakes seen expensive the second of the property of the pr

culating the height of that. I made several observations of the position of the central line of the arch. I might specify that at 9 25 it was at R.A. 20h 42m., Decl. + 33½, and R.A. oh 43m., Decl. + 33½, and it moved very slowly.

Deci. + 33', and it moved very slowly.

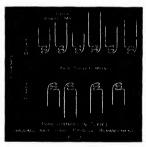

Is it not time some systematic effort was made to calculate
the heights of auroras? A good many observations have been
made on this point, showing great variation in height; and yes,
beyond the conclusion that it seems probable they may be seen at lower elevations nearer the magnetic pole than elsewhere, we know nothing as to whether they vary in height with the place, the time, or the nature of the auroras Now is the time, seeing that auroras appear to be becoming more numerous than they have been for many years past T W BACKHOUSE.

SOME NOTES ON THE FRANKFORT INTER-NATIONAL ELECTRICAL EXHIBITION.

From One Hundred to Twenty Thousand Volts.

THE incandescent lamp having, by 1885, reached a fair degree of perfection, it appeared that the one need still remaining, in connection with the distribution of the electric light over a large area, would be supplied by the use of transformers. For a transformer with many convolutions of fine insulated wire on one coil, and a few convolutions of thick insulated wire on the other, would transform a large pressure and small current into a small transform a large pressure and small current into a small pressure and large current; hence, if such a transformer were placed in each house, it would be possible to light up even a scattered district by a comparatively fine wire from a central station, whereas previously it had seemed

that it would be necessary to use copper conductors many square inches in cross section to light many houses even when at no great distance from one another.

Hence, in the autumn of 1885 we find Messrs, Gaulard and Gibbs making preparations at the Grosvenor Gallery, Bond Street, for establishing there the pioneer central station for London

But the method they adopted was that of placing the transformers in series, as seen in Fig. 2, and this system has the great disadvantage that the brightness of the electric lamps in a house cannot be kept automatically constant when other lamps in the same house are turned

1 Continued from 1. 524.

on or off There are, of course, two conditions to be fulfilled in electric lighting. one, that turning on of lamps in one house shall not affect the brightness of the lamps in one nouse span not affect the original on or off lamps in one room shall not affect the brightness of the lamps in any other room of the same house. With trans-formers in series, the first condition is satisfied by keeping the alternating current which passes through the fine wire or primary cost of the transformer perfectly constant; but this does not render the potential difference between the wires from the secondary circuit, or house mains, independent of the current in this secondary circuit—that is, independent of the number of lamps turned on in the house. Conseof the number of names curred on in the house. Consequently, the series arrangement of transformers adopted by Messrs. Gaulard and Gibbs, while rendering the lamps in one house independent of those in another, did not attain the same result for lamps in different rooms of the same house

Complaints, therefore, became general. Various un-successful devices were tried to remedy this evil, when an application was received from Mr Sebastian Ziani de Ferranti to be allowed to try a transformer which he had designed The application was accepted, for Mr Ferranti, designed the application was accepted, for Mr Ferrant, although quite young, was already known as having constructed an ingenious alternate-current dynamo, and in February 1886 the charge of the Grosvenor Gallery central station passed over into Mr. Ferranti's hands

The new engineer recommended that the system of placing the transformers in series should be totally discarded, and that a parallel arrangement should be adopted

in its place, as in Fig. 3, because a well-made transformer had this important property -that if the potential differ-ence at the terminals of the primary coil were kept constant, the potential difference between the terminals of the secondary coil would also remain nearly constant whatever were the current passing through this circuit; so that if the pressure between the street mains were always kept the same, the brightness of the lamps would hardly be affected either by turning on or off lamps in the same or in any other house.

Placing the transformers in parallel, however, would necessitate working at a low pressure, said the press, and would rob the transformer system of all its value, for "it is surely not proposed for one moment to work a parallel is surely not proposed for one moment to work a parane-system where the primary has a difference of potential of 2000 volts." However, that is exactly what Mr Ferranti not only proposed to do, but what he actually carried out on a large scale, so that his mains by 1888 stretched from Regent's Park to the Thames, and from Chancery Lane to Hyde Park, supplying current to some 20,000 glow-lamps. The Board of Trade had made regulations, about 200 the Doard of Jrace had made regulations, mout 200 volts being the maximum pressure permitted in a house; Parliament had passed the Electric Lighting Act of 1882, containing clauses rendering the development of .be electric lighting industry well nigh commercially impossible; but Mr. Ferranti overcame all these legalities by bridging his mains from house-top to house-top, instead

of putting them under the streets and himself under the control of the authorities.

But every corner at the Bond Street central station had soon to be utilized; a dynamo weighing tons had on one occasion to be lifted into position over a steam-engine necessarily kept always running to maintain a

existing overhead mains, and again reduced to 100 volts

evisting overnead mains, and again reduced to 100 volls on entering the houses, as before.

The scheme was a far-reaching one; permission was saled from the Board of Trade by the London Electric Supply Corporation, the outcome of the original Grosenor Gallery Syndicate, to run wires along 27 railways

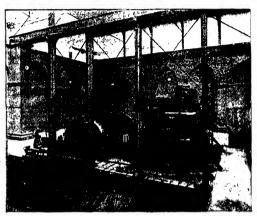

Fig. 4 -Two 1250 horse power dynamos (opened for inspection) at D-peford

constant supply of current to the houses. New customers constant supply of current to the noises. New customers were added daily to the list, more and more current had to be generated nightly, in the face of engineering difficulties, and in the teeth of injunctions against smoke, injunctions against noise. A fresh start became imperative, so it was decided to build at Deptford, 6 miles away from Bond Street, a vast

and through 30 parishes; two dynamos, each to furnish and noting to participate the state of the s

soaked in melted orokent is rolled on, to a thickness of one-eighth of an inch, and the whole slipped loosely into an iron tube, D, Fig. 5, which protects the cable subsequently from mechanical injury To fill up any spaces that may have been left between the iron and the outer copper tubes, the 20-feet section is placed over a

The object of using concentric tubes is wedded—first as the outer copper tube is been practically at the poster-tial of the earth, it is impossible to get a severe shock unless the inner tube is touched, and this, of courte, can only be done by first cutting through the outer; second, the effective increase of the resistance and of the self-induction which occurs with rapidly alternating curricular to the conductor on one another is much less for a given cross section of copper with concentre tubes than with two insulated rodes placed side by side. For example, Sir William Thomson has calculated that if copper be employed in the form of a solid rod, ourself, of a frequency of 80 per second will be 31 per cent, greater than for a steady current.

It is very questionable, however, whether these advantages of using concentructubes are not more than compensated for by the large electrostatic capacity that such a cable possesser. For, as is now fully recognised, the combination of capacity and self-anduction can by a species of resonance cause the difference of potential in the circuit to be far greater than the E.M.F. of the greater than the capacity and approach property of the capacity and in certain cases, very dangerously greater

greater soon as the Depford main was constructed to stand of cox volts, it was found that one of the dynamos seen in Fig. 4 broke down at this pressure, and therefore for many months the current was seen from Depford at only 5000 volts; next, the transformer room at the Grosvenor Gallery was burnt down through carelesaness, some £8000 worth of transformers destroyed, and a portion of London left in darkness for two or three weeks New transformers were healty, too hastily, constructed, and the last December; but after a few days the transformers

fire, and melted wax pumped in between the two through a tube inserted in a hole drilled in the middle of the iron

Fig. 6 shows a cross-section of the finished main full size, and as the sectional area of the metal in each of the copper tubes is about a quarter of a square inch, the main can transmit about 2000 horse-power at 10,000 volts. were, one after another, short-circuited by the electric current sparking from the primary coil to the iron core of the transformers, and all the houses on the London Electric Supply Corporation's system again left in darkness during the nearly perpetual night of a densely foggy winter. The Metropolitan Electric Supply Company which also distributes an alternating current by means of

F10 8.—Ferrants main, jointed r, copper alseve alloyed over, two ends of outer copper tubes, and then corrugated with special tool, o, iron sleeve slipped over, two ends of iron tubes, and corrugated with special tool, n, acrew-hole to run in malted wax, t.

The main being constructed in lengths of only 20 feet, some 1500 pions have had to be made in 6 miles of main, or 6500 joints altogether in the five mains which have been made without solder, in the way shown in Figs. 7 and 8, pressure alone between the copper tubes having been relied on to maintain good contact.

NQ. 1145, VOL. 44]

transformers, but from several central stations in the heart of London itself, and therefore requiring to use only 1000 volts and a single transformation—came to the recue in certam districts, but in others the householders had to be left to their fact, as it would have been far too expensive to run special mains from the Metropolitan Company's stations merely as a temporary expedient.

Finally, in March of this year, current was again turned on from Deptord, at the pressure originally gro-posed, vis. 10,000 volts. It was not, however, supplied from the dynamos illustrated in Fig. 4; bit, instead, Messra. Depret and Carpentier's plan of transforming p. 52a, was employed. For, by this time, two dynamos, formerly at the Grossenor Gallery, each of 600 horse-power, had been taken to Deptord and erected there, as seen in Fig. 9, new steam engines, more powerful than been constructed to drive them, overeor Gallery, having been constructed to drive them.

These dynamos generate the current at 2400 volts, then, by means of transformers at Deptford, this is raised to 10,000 volts. On the power arriving in London, the

London at a pressure which, even at the end of last year, was deemed simply visionary

mussion is a direct year in a control of the property and in a mission is a deray failure, and even that is the advantage of tansmitting the current 6 miles that is in any way commensurate with the capital already expended? When power can be obtained very cheaply, from a rapid river for example, it may be highly remunerative to transport it in some such way as is now being done between Lauffen and Prankfort But can power be obtained so be a control of the control of

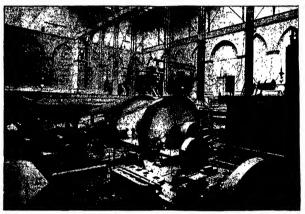

Fig. 9.—Two of the Grosvenor Gallery dynamos re erected at Deptford and driven by new steam angines. Two 1250 horse-power dynamos at the back-

pressure is transformed down again to 2400 volts, and at the houses there is a further transformation of this 2400 volts to 100 volts. There are, therefore, no less than three transformations of pressure between the dynamo terminals at Deptford and the lamps in the houses in London.

London-med as a gigantic experiment in electrical engineering, the Depthord scheme has achieved a gallant victory, for, with a buoyancy that no disaster could crush, and with the determination of a Napoleon to conquer every mechanical and electrical obstacle in the way. Mr. Ferrandi has seep by step succeeded in distributing current to guilty distant parts of London as the pressure which was the support of the control of the service of the support of the service of the service when the base serven months he has been sending the power to

water might perhaps be employed to work condenung accumulations, but such economies can only compensate for a freeign of the yearly interest on the capital expended on the Deptord scheme. Indeed, even if the station at Deptord had been built with rigid economy, and only large enough for the present demand, it is questionable whether the loss of power in three transformations of the pressure would not eat up much of the saving that could be effected by having the generating station quite out of London

formations of the pressure would not cat up much of the saving that could be effected by having the generating station quite out of London As it is, however, the London Electric Supply Company have been so engrossed with the electric lighting to London in the Juffert, that they have practically ignored the present wants of the householder, the vast building at Deptind has been constructed to carry a second story

of boilers and engines, when it is very doubtful if even the present story can be wholly utilized for a long time to come; rows of boilers and furnaces were erected some two or three years ago to supply steam to drive dynamos which are not yet made, tens of thousands of pounds have been expended on machinery to be employed in constructing two ten-thousand horse-power dynamos, and the armature of one of them, 43 feet in diameter, has had to be left abandoned only half finished, hecause there is neither money nor present need for such a dynamo at

Deptford. And while all these provisions for the future electric lighting of London on a vast scale were slowly proceeding, the present customers were left sometimes for hours, sometimes for days, and occasionally even for weeks in darkness: what wonder is it, then, that all over London there have have been growing up central stations supplying a direct current at low pressure, and that many of the house-holders who formerly received current from the overhead wires of the London Electric Supply Corporation

head wires or inc London Lectric Supply Corporation have had their houses connected instead with the low-pressure underground mains of other companies? To the world at large, however, the Deptford under-taking has been of immense value, for it has shown the possibility of practically using the very high potential differences absolutely necessary for economically transmitting power over such distances as that between between base wires running for 109 miles along the side of the Neckar railway, at a height of only 16 feet from the ground, sounds much less startling now than did Mr. Ferranti's proposal made and acted on five years ago to bring only one-tenth of this pressure, by means of india-rubber covered conductors, into locked transformer rooms built of brick in the basement of the houses supplied with current from the Grosvenor Gallery

In fact, the results that have been attained through Mr. Ferranti's undaunted courage, and the well-filled purses of his friends, have led people to look on a pressure of 20,000 volts as they regard a velocity of 70 miles an hour, so that to day, in order to prevent boys climbing up any one of the 3000 ordinary telegraph poles which carry the wires from Lauffen to Frankfort, it is thought sufficient to merely paint a skull and cross-bones on every post as an indication of the deadly fate that awaits the climber.

MY DEAR LORD RAYLEIGH,—As you are aware,
MY DEAR LORD RAYLEIGH,—As you are aware,
24/9/9/10 ill a fortught after its date; and my reply has
been further delayed for a week in consequence of the
closing of Edinburgh University Library at this season
Evennow I can refer only to the German version of Van der Waals's pamphlet

or waars pamphiet Partly on account of its unfamiliar language, but more especially on account of a very definite unfavourable opinion expressed by Clerk-Maxwell (NATURE, 15/10/1). I did not attempt to read the pamphlet when it appeared; and It was not till 1888 that, in consequence of some hints from Dr. H. Du Bois, I hastily perused it in the Germán form.

from Dr. H. Du Bois, I hastily perused; in its Germán form. The passage which you quote from my pager (where, by the way, the printers have unfortunately put resistance for resistance; to certainly not a very accurate description of Van der Waals's method, but it represents faithfully the difficulties which I felt on first reading the pamphet. I said that 'Vign der Waals's "justification of the introduction of the tergé pir ion to an account altendy closed, as it were, We have to thank the Electrician and the Electrical Review for some of the illustrations used in this article.

escapes me." And I am not surprised that it did so. For the statement of Clerk-Maxwell had prepared me to look for error; and when, at the end of Chap. VI., I met with the formula

$$p(v-b) = R(1+at),$$

which, a couple of pages later (nothing but general reasoning intervening), somehow developed itself into

$$\left(p + \frac{a}{a^2}\right)(v - b) \Rightarrow R(1 + at),$$

I naturally concluded that this was the matter adverted to I spoke of the first of these equations as a "closed

to 1 spoke of the first of these equations as a "closed account," because of the process by which b had been introduced. To this point I must presently recur. I had not examined with any particular care the opening chapters, to which your letter chiefly refers, probably having supposed them to contain nothing beyond a statement and proof of the Vinail Theorem (with which I was already familiar) along with a reproduction of a good deal of Laplace's work.

Of course your account of this earlier part of the pamphlet (which I have now, for the first time, read with care) is correct. But I do not see that any part of my care) is correct. But I do not see that any part of my statements (with perhaps the single exception of the now italicized word in the phrase "the whole procedure is erroneous") is invalidated by it. No doubt, the sudden appearance of $a/\sqrt{2}$ in the formula above quoted is, to appearance of alvo in the formula above quoted is, to some extent at least, accounted for; but is the term correctly introduced? The formula you give would lead, on Van der Waals's principles as to the interpretation of \$2(mV^2), to

$$v(t + K) = R(1 + at).$$

$$v\left(p + \frac{a}{v^2}\right) = R(t + at)$$

But how can the factor ($\nu - \delta/\nu \tau$, which Van der Waals introduces on the left in consequence of the finite distinction of the particles, be justicably applied to the term in Van der Waalse theory; for without it the resulting equation will not give a cube in ν , and cannot therefore be applied to the isothermals for which it is required. And, in any case, it could searcely be said that the K term, after being manipulated in this manner, is, in any strick sense, "extracted from the term $2(N_{\nu})$ ".

A very strange thing appears, in this connection, in the German version. A result, due it seems to Lorentz (which, in ignorance of his work, I had reproduced and published in the first part of my paper), leads directly to the equation

$$pv = R(1 + at)\left(1 + \frac{b}{2}\right);$$

which is then put in the confessedly approximate form p(v-b) = R(1+at).

Of this it is remarked.—" was genau mit dem obigen Resultate [that obtained by the use of the factor (v-b)/v] ubereinstimmt." It is obvious that, when we have to divide both sides by v-b, we ought to restore the proper factor on the right; and thus that the equation ought to take the final form

$$p + \frac{a}{v^3} = R(t + at) \frac{v + b}{v^3},$$

instead of the more convenient form

$$p + \frac{a}{v} = \frac{R(1 + at)}{v - b},$$

in which Van der Waals employs it. But then it would

not give the required cubic in v'

I think that the mere fact of Van der Waals's saving (in a passage which is evidently applicable to his own processes, though it is applied only to that of Lorenty, "die ganne Rechaung doch nur bus auf Grossen der ersten Ordsung (wee http://die.ganne Rechaung doch nur bus auf Grossen der ersten Ordsung (wee http://die.gann. ist" throws very grave doubt on the whole investigation. For in the most interesting part of the critical isothermal of CO₂ the fraction http://die.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.ganne.gann

For, if we take the experimental test, there can be no doubt that; as I have stated in , §6 of my paper, "Van der Wash's curves cannot be made to coincide with those of Andrews". And I think I have given reasons for beheving that "the term of Van der Wash's equation, which be rook to represent Laplace's, is not the statical which be the control of t

Believe me yours very truly,

St. Andrews, September 28

THE EXISTING SCHOOLS OF SCIENCE
AND ART

 \boldsymbol{A}^T a meeting of influential science and art teachers held at the Charterhouse School of Science and Art, Goswell Road, on the 3rd instant, the position of existing schools, with regard to the fierce opposition offered by highly endowed Polytechnics, was calmly and broadly discussed.

For many years, under the system not only recognized but encouraged by the Science and Art Department, schools have been established in London and the probable of the properties of the propert

By recent Acts of Parliament agreat impetus has been given to that side of science and art instruction known as technical education. Funds which in past times could only have been raised by persistent begging are now forthcoming almost as a matter of routine. In the provinces there is every sign that the authorities having the administration of the grant of public moneys intend to recognize existing schools. In London it is not so Schemis for the erection of new buildings are pushed officing agod work. At the meeting of teachers already referred to several instances were cited. The People's Palaco, erected almost in the very shadow of the Bow and Broniley Institute, has, by reason of its endowment, greatly hampered and herased the older institution.

The West London School of Art succumbed two years ago to the state of the Regen Street Polytechnic, and now the St. Martin's School of Art, one of the best known centres of instruction in the metropolis, has closed at doors. Without endowment it could not compete this more favoured rivals. The closing of this school is the more to be regretted because of the high tone of the work carried on within its valie.

Unfortunately, it cannot be densed that many so-called schools of science and art are simply carred on as "grant-earming" establishments, and the country would lose little or nothing if they were closed at once. But there are others affording excellent science and art instruction; and though these may not be affected by the present Joly-the erection of other buildings will, if not properly thecked, raise an undigmed competition with the older schools it is therefore a matter of great public importance that the established mustuleness should not be overclosed by the London County Council If new buildings are deemed the treated as the nucleus of the enlarged scheme out.

Two points of errors eem to be apparent in the plan of campaign of the supporters of Polytichius «(1) that educational work must be associated with recreation, and (2) that te.hincal education has a very limited area, and that science and art education in its fullest sense is unnecessary.

"Schools of art," said a goilleman to me recently, "are dead" Surely nothing could be more about. As I understand technical education, it is the application of general principles to a specific purpose Schools of science and art—r schools for it estudy of science as science, and art as art—should be encouraged as much as before. This can be done without interfering with the specific application of such study to a particular purpose

With regard to the question of seferation, I thinke would be found that, allough those institutes which make much of athleticism and such matters attract the largest proportion of students, the attendance per ratio in the classrooms, and the results obtained there, would not favourably compare with a mistitute carrying on its purely checked the students of the classrooms, and the results obtained there, would not favourably been connected only seven students entered the class, scores of young men could be found in the billiard-room and gymnasum At the Seence and Art Institute, and gymnasum At the Seence and Art Institute, in the country, it was decided to cluse the billiard-room in consequence of the serious effect it had upon the attendance of students at the classes. I am personally acquainted with the science and art work carried on at the Regent Street Polyrechnic Excellent as it is, it would be resembled.

The London County Council has shelved for a time the appropriation of the funds provided by the Excise Act, 1850, for the promotion of technical education But the matter must soon come up again. Healthy competition is excellent, but that the state of the state of the council to the state of the state of

In concluding, I would point out that the exponents of technical instruction are too keen on "centralization." Let us have large buildings with costly apparatus and every convenience, but do not entirely crush the small schools. To the working man with limited time and means, weary with his day's toil, a modest school close at hand is of greater service than a huge building six miles away involving railway fare and loss of time. By careful involving railway fare and loss of time. By Carestii arrangements such smaller schools can be preserved, and largely used as "feeders" for the institutes of magnitude. The whole matter, therefore, of science and art schools and future Polytechnics should be referred to duly quali-

There is no reason why existing machinery should not fit in with the new plant to make an harmonious OLIVER S DAWSON.

whole.

MOTES

THE autumn meeting of the Iron and Steel Institute was opened at the Royal Arsenal, Woolwich, on Tuesday, the greater part of the day being devoted to an examination of the various departments of the Arsenal, On Wednesday papers were discussed, and to day visits are to be made to the Naval Exhibition, the Enfield Small Arms Factory, and the Thames Iron Works. We hope to print next week an account of the proceedings,

An exhibition of cone-hearing trees and shrubs, asters, and sunflowers, and a conference upon them, were opened in the Royal Hortieultural Society's Gardens, Chiswick, on Tuesday. Large numbers of consiers were sent from various parts of the country, no fewer than 30 collections coming from Scotland The first prize was awarded to the Dowager Marchioness of Huntly for her collection of conifers, the second to Lord Wimborne The largest araucsuan cones were sent from Lady Fortescue's. at Dropmore, Maidenhead, where there is an araucana 68 feet high-the tallest male araucaria in this country Kew Gardens contributed about 200 different confers. On Tuesday papers were read on asters and sunflowers. The conference on conifers began on Wednesday, and is being continued to-day

A COMMISSION of engineers representing the various European Powers is to meet shortly at Cairo to consider the question of a storage reservoir, and to advise the Egyptian Government on the subject. The Commission will be required to select a site to the north of Wady Halfa, or within the present limits of Egypt.

THE organizers of the International Folk Lore Congress are to be congratulated on the success of their undertaking. The attendance was good; many excellent papers were read; and there were animated and suggestive discussions on most of the problems which are now of especial interest to students of folklore. Mr Andrew Lang, as President, delivered the opening address, in which he presented a most interesting statement of what he conceives to be the fundamental principles of the science. Admirable addresses were also delivered by Mr. Sidney Hartland, Prof. Rhys, and Sir Frederick Pollock, who presided respectively over the Sections devoted to folk-tales, mythology, and institutions and customs. The members of the Congress dened together at the Criterion Restaurant on Tuesday

STUDENTS of psychology and philosophy will read with regret Prof. Croom Robertson's "valedictory" words in Mind, from the editorship of which the state of his health makes it necessary for him to retire. For sixteen years he has done his mark as edstor with conspicuous ability and success. A second series of the Review will be begun next quarter. It will be under a co-operative direction which promises, Prof. Croom Robertson thinks, "a far more effective covering of the ground of psychology and philosophy than has hitherto been attained."

THE seventh of the series of One Man Photographic Rubibitions is now being held at the Camera Club. It is open to visitors from 10 a.m. to 4 p.m. on presentation of cards, which can be obtained from members or from the Hon. Secretary. The exhibition consists of photographs by Mr. Ralph W. Dahinson

WE learn from the Bolanical Gazette that Mr. O. F. Cook, Instructor in Biology at the University of Syracuse, U.S.A., intends starting about November 1 in charge of an expedition to Liberia and other parts of Africa, with the object of studying the natural history of the country, especially the plants and insects Mr. Cook will be glad to hear from anyone who would like to have material from that region

YESTERDAY evening a meeting of the Medical Society. University College, London, was held in the Boianical Theatre, University College. Dr W H, Gaskell, F R.S., delivered an address on a new theory of the origin of Vertebrates, deduced from the study of vertebrate anatomy and physiology

THE Belgian Minister of Public Instruction offers a prize of 25,000 france for the best memoir on the meteorological, hydrological, and geological conditions of the countries of equatoria Africa, regarded from the sanitary point of view. The subject must be studied with special reference to the welfare of Europeans resident in the Congo State.

In the Proceedings of the Academy of Natural Sciences of Philadelphia for 1891, some parts of which have just reached us, there is an excellent memoir of the late Dr. Joseph Leidy, by Dr Henry C Chapman. It is followed by a list of Dr. Leidy's numerous writings

IN a valuable paper on the "Rapakiws," J. J Sederholm, o the Geological Survey of Finland, has furnished petrographers with a trustworthy description of the mode of occurrence and minute structure of a granitie rock which has excited much interest, but has hitherto been very imperfectly understood. The official maps of the district where the Rapakiwl is found, with the accompanying memoirs, were published about a year ago : and the last number of Tschermak's Mineraloguichen und Petrographischen Mittheilungen, now edited by Dr. F. Becke contains a full discussion of the petrological peculiarities of the rock Writing from the famous laboratory of Heidelberg, Herr Sederholm naturally adopts the nomenclature of Prof. Rosenbusch, and it would appear from his description that the Rapawiki will have to take its place among the numerous types of "granophyre" (using this term as Rosenbusch does, and not as originally defined by Vogelsang) which constitute links between the plutonic granites and the volcanic rhyolites. The excellent photographic illustrations accompanying the memoir give an admirable idea of the peculiar nodular structure of the rock, which has attracted to much attention to it. In the same journal, we find a second memoir by Herr Sederhoim, on the Archeen rocks of South-West Finland, describing a varied series of igneous rocks, and discussing the effect of dynamometamorphic action upon them. The general conclusions of the author agree with those to which the study of similar rocks in other districts has led Lossen, Roland, Irving, Lehmann, Williams, Reusch, and Teall,

EXCELLENT arrangements have been made for the establishment of a good system of technical instruction in Essex. organizing joint committee of the County Council and the Essex Field Club was lately appointed to deal with the question, and funds were placed at its disposal. This body has now assesd a preliminary schedule of subjects to be taught. Local technical instruction committees are invited to select from the list one or more subjects which they may deem specially suitable for their respective neighboushoods. When several such bodies, representing adjacent districts, have chosen a particular subject, the origanisting committee will select a teacher or lecturer, and anderworr to arrange a circuit for him comprising the contres needing his service, apparents and illustrations being provided by means of the fund for that purpose. By this seems the said of throughly qualified and equipped instructors may be obtained by the local committees at a cost considerably less than would be incursed of seed contra were to act independently.

STRENUOUS efforts are being made in Scotland to secure that the country shall be supplied with a sound and adequate system of technical instruction. An important public meeting will be held at Edinburgh, on Thursday, October 20, for the considera tion of the subject Lord Eigin will preside, and it is expected that several members of both Houses of Parliament, and others interested in the question, will take part in the proceedings The following are the provisional agenda -(1) Chairman's address, (2) report on action taken up to this time by Town and County Councils-(a) in England, (b) in Scotland-with reference to the application of the sums available for technical education under the Local Taxation (Customs and Excess) Act. 1890 : (1) the relation of the Local Taxation Act to technical (including commercial and agricultural) education, (4) report on various agencies already available for technical instruction in Scotland-(a) in rural districts, (b) in towns; (5) the amendments necessary in the Technical Schools (Scotland) Act, 1887.

This Nicholson Institute, Leck, of which for Philip Megans President, his stuest its Calendar for the session 1891—21, and as is damirable Calendar it it, presenting many wrated elements of Interest. In the technical school connected with the Institute there will be classes for the study of wood carring, modelling, seeding, hyperies, and other subjects and in the "second physicians," and produce the second physicians of the subjects and in the "second physicians" and produced the second physicians of the subject of the second physicians of the subject of the second physicians of the second physicians and solid geometry.

An Agricultural and Mechanical College is about to be established at Sdo Paulo, in Brasil, an endowment of 200,000 dollars having already been promised, and the further aid of the Government secured. The Presidency of the College has been offered to Prof. L. H. Bailey, the American botanist.

In the Report for 1891 of the Governors of the Baltimore Fishing School, an Interesting sketch of the history of the institution is given. The progress of the school encourages the Governors to believe that its success will prove of great advantage to Irish fisheries. They point out, however, that its operations are not on the enlarged scale originally contemplated; and to all who can appreciate the importance of the youth of the Irish coasts being trained in remunerative industrial pursuits, the Governors appeal for contributions to enable them to extend their work The boys are thoroughly instructed in everything that pertains to the labours of fishermen. They also receive the literary education usual in such establishments; and a special class has been formed for the teaching of elementary navigation in connection with the Science and Art Department. At the last examinstion in this subject twenty-four pupils presented themselves Of these, not one failed, twenty-two passing in the first division, and two in the second

We have received from the Meteorological Conneal a copy of the "Meteorological Observations at Studens of the Second Order" for the year 1887, containing observations and results for 66 stations. At 21 stations the observations taken at 9th, nm. and 9th, pm. are practed in acteurs, and the whole work is on the same plan as in the volume for 1886 (NATULE, vol. 2011, p. 20), via the bacometer observations are given whither freedenin to see-level, and the differences between the grand uset built thermometer ceedings are given as the "degression of set-bold." The maximum can inflations the video-

meters are read at 9h. p.m , and the readings entered to the day on which they were read. The rainfall is measured at 9h. a.m., and the amount registered entered to the previous day. Fog is only entered when the observer is quite enveloped in it. This work has been continued in a more or less complete form since 1866 (when, however, there was only one station); and the summaries contain, sater alsa, very useful resumes of the state of the weather and wind-distribution, and afford excellent materials for preparing a revised climatology of the British Isles. The work is accompanied by a key map, showing the distribution of the stations, and indicating those which belong to the Royal and Scottish Meteorological Societies it will be seen that all distracts are well represented except, perhaps, on the more exposed western coasts and islands A special table is also given, showing the number of hours of bright sunshine in each month for those stations at which sunshine recorders exist

THE Chief Signal Officer of the U S Army has, just before the transfer of the Meteorological Service to the Agricultural Department, issued three atlases, bearing upon the meteorology of the Housed States, showing-(1) The isolars, isotherms, and winds for each month from January to December for the years 1871-73, 4 period prior to the regular publication of the monthly chaits The data used include all the materials possessed by the Smithsonian Institution (2) The probability of rainy days, prepared from observations for 18 years (1871-88) The average number of such days for all months and for each station has been calculated, and the percentages thus obtained are graphically shown on the charts. The data show great differences of distribution of rainfall in localities not far distant from each other; the influence of the prevailing direction of the wind in increasing the number of rainy days is particularly noticeable in the Lake region, (3) The average monthly cloudiness for the period 1871-Cloud observations show indirectly the relative amount of sunshine, as it may be assumed, within reasonable limits, that the complement of cloudiness will be sunshine. The investigation of this element is useful in determining the suitableness of certain localities for health resorts, or for the ripening of crops, and the charts may be considered as standard cloud maps of the United States.

De Kind, Director of the Bidnical Survey of India, has used a Report on the working of the Bonancial Survey in Assan and Burmah, for which 2002 repea are annully allowed, whi wire to arranging a plan for working by native collectors. Dr. King vailed Assan in the latter half of hat year, and found the local authorities ready to afford every assistance. Two native collectors were secured, and set to work near Golighds, and in the Knaist Hill be The Conservator of Forest also seen a large number of specimens to the Herbarum at Collection, and a Eurosau collector was employed for a time in Cachar, more consistent of the Conservator of the Conservator of the Conservator of the Conservator of the Conservation of the Conser

Dr. Paarn, the Cursion of the Herbarium of the Calcium Ensurial Genetics, accompaned the surveying the Journal Journal Confession design design part of her operations in the Bay of Heeps law and the case of the Creek Cook Island for a few days, and was the easibled to pay solely right to the Little Cook and to Entitled District State of the Creek Cook Island for a few days, and was the easibled to pay solely right to the Little Cook and to Entitled District. Except for the vipit match by a Cook and no before been explored by a blandful, that Little Cook and Resisted Headan were this year wisted for the first time. Accounts of these visits are to be officially positived in dec course.

A NUMBER of small expeditions in the Chin Hills and on the Bhamo frontier of Upper Burmah have been arranged for next cold season. In the Chin country, a column will explore the Chinboh country, and four other columns will visit the Baunghshe, Tashon, Tlangton, Kanhow, and Nwengal tribes. In order to effect a settlement of the Kachyen tribes, columns will be sent out from Bhamo, Moroung, and Myltkynia. An expedition will also proceed to explore the amber-mines and the indus-rubber tracts, and, if practicable, join hands with Assam,

To estimate the relative ments of different kinds of points for lightning conductors, Dr Hess recently collected and examined nineteen heads of conductors that had been struck by lightning (Riectrot. Zetts) His conclusions are as follows: (1) the fusion of points of lightning conductors by lightning causes no danger of fire through scattering of fused drops, for this does not occur : (2) fine and smooth points receive the lightning stroke in concentrated form, while sharply angled and ribbed, also blunt points, divide it into threads . (3) platinum needles and tips have no advantage over copper points ; (4) there are lightning strokes which are capable of making brass wire 7 2 mm. (say 0 20 inch) thick, incandescent. Unbranched copper conductors should therefore never be thinner than 7'0 mm

In submitting to the Wellington Philosophical Society some "Coccid Notes" lately, Mr. W. M Maskell expressed regret that entomologists generally did not devote more attention to the Cocoldee. He believed he was the only person in New Zealand who had published anything on the subject. In the Coccider there was infinite variety—a variety of life-history, habits, and customs that seemed greater than that afforded by any other branch of entomology. He gave instances of piculiarities in these insects-wonderful vitality in some cases, and the boring habits of one particular insect after it had thrown off legs, mouth, &c -all tending to prove that these little despised creatures were more interesting for study than "all the butterflies"

FARMERS in many parts of Victoria seem to be fully alive to the necessity of adapting their methods to the conditions under which they have to carry on their work Mr David A Crichton, in a report printed in the latest Bulletin (No 12) of the Victoria Department of Agriculture, says that, although farmers are supposed to be too conservative in their practice to do much in the way of new industries, he has been agreeably surprised to find that a very large number are anxious to try crops other than cereals Fruit culture in particular is attracting great attention, and he feels confident that before long it will become one of the stanle agricultural industries of the colony He is doing his bes to stimulate this particular industry, and, In addition to the information afforded by his lectures, he makes it a practice to visit as many places as possible, to advise upon the selection of sites for orchards and vineyards, and give practical lessons in pruning, training, and other matters. He finds that this assistance is highly appreciated, and his services are in great demand in this respect Mr Crichton's position in connection with the Victoria Department of A reculture is that of "the fruit and special industries' expert '

MR. JOHN H COOKL is publishing in the Mediterranean Naturalist an interesting series of observations on the geology of the Maltese islands. In the September number he refers to Cala Helv, a little bay between Comino and Commotto. On a bright day, he says, this bay presents an endless succession of the most brilliant colours, "which commences with a deep blue, and from thence passes through every conceivable gradation of green, orange, and white, after attaining the last of which it again graduates onward in the distance to that cerulean blue that is so characteristic of Mediterranean waters." The setting of the picture is not less effective than the picture itself. Arous the bay are many caverns, which have sombre-looking entrances | describes, for the first time, the neutral sulphate of hydrasine

and wildly-fantastic shapes. The sides of these caverns are full of interest for geologists, as "they literally teem with the remains of creatures that formerly lived and died in the waters in which the islands were built up

MR. W PRENTIS, of Rainham, Kent, describes in the October number of the Zoolsgust an Interesting case of a wild duck's foreth night. A mowing machine was set to work round the outside of a field of Jucerne bordering a marsh, diminishing the circle each time round the field, leaving about two acres in the centre. A wild duck was seen by the shepherd to fly from the piece of lucerne that was left with something in her beak, and, happening to fly near him, she dropped a three parts incubated egg. She was again observed by the shepherd, and also by the

sheep shearer, carrying another egg in her beak, this time over the marsh-wall towards the saltings, and again she was seen for the third time carrying an egg in her beak in the same direction. Next day, when the field was "finished" by the removal of the last piece of lucerne, the wild duck's nest from which the eggs had been removed was discovered.

MR. W. H HARRIS, Ealing, records in Nature Notes (September (5) a remarkable instance of "fringality" in bees. The recent extremely rainy weather seems to have suggested to his bees that there would probably soon be an end of honey-making. Accordingly, although there was " a crate of fairly filled sections above the stock-box," they adopted vigorous measures to prevent future inconvenience "It is a positive fact," says Mr. Harris, "that my bees, not content with ejecting larvæ of both drones and workers, proceeded to suck out the soft contents of the corpses, leaving only the white chitinous covering, which had not hardened sufficiently to prevent the workers from piercing it with their mandibles, and then inserting their tongues,

MESSES R FRIEDLANDER AND Son, Berlin, send us the latest of their catalogues of botanical books. This list, besides various works on the distribution of plants and on botanical exploration, includes a great number of writings on the flore of different parts of the world

MESSRS KFGAN PAUL, TRENCH, TRUBNER, AND CO. announce the following books on scientific subjects :-- "Colour Blindness and Colour Perception," by F W Edridge Green. M D., with three coloured plates (International Scientific Series); "Descriptive Catalogue of the Nests and Eggs of Birds found breeding in Australia and Tasmania," by A J. North, with 21 full page plates, "English Folk Rhymes," by C F Northall ; the following volumes of a series, "Modern Science," to be edited by Sir John Lubbock-"The Cause of an Ice Age," by Sir Robert Ball, F.R S , "The Horse : a Study In Natural History," by William Henry Flower, CB, "The Oak a Popular Introduction to Forest Botany," by H. Marshall Ward, FRS, "The Laws and Properties of Matter," by R. T. Glazebrook, F.R.S. ;-"On Seedlings," by Sir John Lubbeck, with numerous figures in text: "How to Use the Ophthalmoscope," elementary Instruction in ophthalmoscopy, by Edgar A. Browne, fourth edition, completely revised; "Principles of Political Economy," by Arthur Latham Perry; "Moral Order and Progress," an analysis of ethical conceptions, by S. Alexander, second edition (Trubner's Philosophical Library); "Chemistry of the Carbon Compounds, or Organic Chemistry," by Prof. Victor von Richter, authorised translation by Edgar F. Smith, new and enlarged edition.

Two more papers by Prof. Curtius, upon the reactions of the hydrate of his recently iso'ated hydrazine or diamidogen, NH, , are contributed to the most recent numbers of the NH_2

Journal fur praktische Chemie. The extler communications

(N₁H₃), H₂GO₂. Hydramae is found to form two sulphates—an add one, NiII, I, I₃GO₃ and the neutral one now described. The acid sulphate is a beautifully crystalline salt—an account of which was given in NATURE, vol. kim. p. 205. It is distinguished by its high melting point, 25° C, and its distinguished by its high melting point, 25° C, and its distinct solution. The neutral sulphate now described is obtained by evaporation of the solution formed by neutralizing hydrama hydrate with distlet sulphuriz each, first, over a water bath, and finally, as the new sail is very deliquencent, as neuron. It crystallines in large brillian tables, melting at 85°, It is prespirated exhaults in large brillian tables, melting at 85°, It is prespirated values in large brillian to a fine was 10° C, which is the summarized with a gilass root, and in contact with a small crystal of the sail, numediately solidifies to a fine mass of crystal, which, like those obtained by evaporation, consust of an hydroxin (N₁II), II, I₁C, and its distribution of the consumer of the consumer of the proporation, consust of an hydroxin (N₁II), II, I₁C, occussed of the solid presporation, consust of an hydroxin (N₁II), II, I₁C, occussed of the solid presporation, consust of an hydroxin (N₁II), II, I₁C, occuss of an hydroxin consumer of the solid preservation (N₁II), II, I₁C, occussed on the consumer of the con

THE second and much longer communication describes an important series of new compounds, the ketazines, obtained by the action of hydrazine hydrate upon ket new: The simplest of these new substances, the one obtained by the action of hydrazine hydrate upon acctone, is represented by the formula CH₂.

CH₂.

CH₃.

CH₄.

When bydrazine hydrates is dropped.

CH — When hydrazine hydrates dropped Upon acetone, a most violent reaction occurs, resulting in an explouon unless the acctone is surrounded by a freezing mixture When than moderated, however, the substance above formulated is produced together with water, the reaction occurring according to the following counting:

$$^{\text{CH}_{8}}_{2}$$
CO+N₈H₄ H₈O= $^{\text{CH}_{8}}_{\text{CH}_{4}}$ C=:N-N-C $^{\text{CH}_{8}}_{\text{CH}_{4}}$ +3H₄O

By allowing the product to remain for some hours in contact with caustic potash the water is removed, and upon distillation the new ketazine passes over in the pure state. It is a clear liquid possessing a sharp odour somewhat resembling that of the alkaloid coniine. It boils without decomposition at 131°. By employing other ketones, such as methyl ethyl ketone, diethyl ketone, and others of the same type, a large number of these ketazines have been prepared. Those containing fatty radicles are liquids, and those containing aromatic groups are solids. The lowest members only dissolve in water, the solubility rapidly disclaishing with mcrease of carbon atoms. Acids decompose them in the cold, with assimilation of water, into their constituents; towards alkalies, however, they are comparatively stable. Light exerts a decomposing action upon them, specimens placed in bright sunshine rapidly becoming yellow. Reducing agenta, such as sodium amalgam, are without action upon them, and they appear further to be incapable of reducing either Fehling's solution or (except after long boiling) ammoniacal solutions of silver salts.

The comet is therefore in Equuleus at the present time, and moving towards Perasus.

PHOTOGRAPHIC DEFINITION.

T is a matter of some interest to determine what are the ilmits to the definition obtainable in photographs. In examining this question, three distinct classes of problems present them-

this question, time of an increases or proteins present themselves—namely.—

(1) Those depending on the wave-length of light, and the action of a perfect lens on such wave-lengths.

(2) The various abstrations of real lenses

(3) The qualities of the different sensitive surfaces on which

(3) The qualities of the dustreat sensitive stratects on which the pictures are formed. Taking these divisions of the subject in the order given, I will inquire first what is the limit to photographic definition on the supposition that the less has no aberation of any kind, *c that all the waves which reach it from any point arrive at the image.

of that point in the same phase. of that point in the same phase.

The image thus formed consists, as is well known, of a bright disk surrounded by alternate dark and bright rings, the intensity of the illumination of the rings decreasing rapidly at each successive ring, reckoning outwards from the centre.

All no dref that the images of two neighbouring points may seem to the contract of the contract of the received that the images of two neighbouring points may

Points nearer to, or further from, the lens than that which has its mage on the plate will be represented on the latter by round patches of light; these being the sections by the plate of the patches of real patches of the point, and for their slant the radius of the aperture—focal length. Thus, if \(\epsilon \) the stantance before or behind the plate of the focus of a point, it will be represented on the plate by a patch of light of diameter.

This diameter can be diminished by the use of a disphragm, i.e. by diminishing A, but this at the same time increases the diminishing A, but the same time increases the And the resulting average definition will be improved by diminishing A until the patch of light, representing the point most of focus, has the same diameter as the diffraction disk of the image point in focus.

If we suppose the photographic plate to be placed at such a distance from the lens that the focus of the nearest object is as much behind the plate as the focus of very distant objects is in front of it, we shall have, to determine the diameter of

Fig. t

appear separated from one another, the central disks of their images ought not to overlap. If the disks are just in contact, it is possible that they would appear as a double object in the photograph, and this may be taken as the limit of the defining power of a lens. (See Aly "On Light", and Lord Rayingh "On the Theory and Manufacture of Diffract, in Gratings," The Raying of the Control of th

But, in ordinary photography, objects at very various distances have to be simultaneously represented, and it is to the definition attainable under these circumstances that I wish now to direct attention.

On referring to the papers above-mentioned, it will be seen that the diameter of the central disk is

where A is the wave-length of light,

F the focal length of the lens. A the aperture of the lens.

This gives the effective diameter of the image of a point truly in iocus when not far removed from the axis of the lens.

the stop giving the best average definition, the following equation:-

Putting F = principal focal length,

D = distance of nearest object, $q = 1.210 \lambda$

$$q \frac{F + \epsilon}{A} = \epsilon \frac{A}{F + \epsilon};$$

$$\therefore q \frac{(F + \epsilon)^2}{A} = A^2 (1)$$

but, by the ordinary formulæ, connecting the conjugate foci of lenses, we have, if D = F + g,

$$2\epsilon_{ij}' = F^{i};$$

 \vdots $\epsilon = \frac{F^{2}}{2\epsilon'} = \frac{F^{2}}{2(U - F)};$

This is an approximate statement only. The true expression involves an involvestation of the intensity of the light knowledgesty in front of and behind a caustic

whence, substituting for e in (1) we have

$$A = \sqrt{\frac{q}{2}} \frac{2D - F}{DF} \dots (2)$$

Let the nearest object be at n times the focal length of the lens. Then, putting nF for D.

$$A = \sqrt{\frac{qF}{2}} \frac{2n-1}{\sqrt{n-1}} \dots (3)$$

This gives the value of A as a linear quantity; it is usual however, to reckon the diameter of stops as fractions of the foca

Dividing, therefore, (3) by F.

$$\frac{\Lambda}{F} = \sqrt{\frac{g}{2F}} \frac{2n-1}{\sqrt{n-1}} \dots (4)$$

From (4) the accompanying table has been computed, giving A for various values of F and n. (Fig. 1 gives the same graphically.)

Table showing ratio of aperiure to focal length which gives the best average definition when the nearest object to be photographed is at "n" time the focal length of the lens, and distant objects are also in view.

F	***	N=10	#m12	n= ≥0	###25	# = 3 0	n=35	N=40	n=45	#III 50

6	00392	00152	00551	0276	9985	0093	1010	0108	0115	0122
8	00170	B2520	00615	0071	OU83	oo\$8	0005	0102	0119	0115
90	00350	00404	00584	no58	0076	0084	00,00	0007	0103	0109

I have not before seen it pointed out that the ratio A, which gives the best average definition, alters with the value of F If a is the least angular distance between two points (as seen from the centre of the lens) which are shown as separate points on the photograph, a must at any rate not be less than 4, or

$$\sqrt{\frac{2d}{F}} \sqrt{\frac{N-1}{N-1}}$$

showing that, if the foreground is kept at a distance proportional to the focal length of the lens, the definition improves with an increase of the focal length.

On the other hand, if the nearest object is at some fixed dis-

tance. D. from the lens, we have as the limit for a,

$$\sqrt{2q} \frac{\sqrt{D-F}}{2D-F}$$

an expression which increases with F, so that for a given picture taken from a fixed position, definition will be gained by the use of a short focus.

The gain, however, is this respect is not great, for in practice D is always a considerable multiple of F, and writing

$$\sqrt{\frac{1}{4D + \frac{F^2}{D - F}}}$$
 for $\frac{\sqrt{D - F}}{2D - F}$,

it will be seen that when D is many times F, The R may be neglected in comparison with 4D.

Thus, in ordinary cases the limit for a is $\sqrt{\frac{q}{2D}}$, and is independent of the focal length of the lens employed.

If we inquire how close the nearest object may be to the lens

NO. 1145, VOL. 44]

when a view containing also distant objects has to be photographed with a definition reaching a certain standard, we have, on the above supposition,

and if we put a = t', which is often taken as the least angle separable by the unaided eye, and λ as write inch.

showing that if the picture is to appear as well defined as the natural objects themselves, to the 9 placed at the position of the lens, no object in the view must be nearer the later than about 73 feet?

Though, as above stated, the focal length does not affect the definition, when the right-stand ston is used.

definition, when the right-sized stop is used, it does the rapidity with which a picture may be taken, for the intensity of the light

with which a picture may be taken, for the intensity of the light on the plate is measured by $\frac{p_s}{k^2}$ or $\frac{q}{r} (\frac{2n_s}{n^2} - \frac{11}{n^2})$. That is, in these circumstances, the exposure is Inversely as the focal length.

All that has been higher to said refers to the definition in the

All that has been hutherto said refers to the defination in the central parts of the plate.

The definition for the oblique pencils is necessarily worse. For even if it were a sament that the lone was perfect for oblique years in the plate of the plate. The passemption, however, that a less is perfect for oblique pencils is too far resurved from extend fact to make it worth

while to consider the results to which such a supposition would lead

The definition for the marginal parts of the photograph depends on the various aberrations which all combinations of lenses suffer from in some degree, but which in well-made examples are completely, or almost completely, corrected for direct pencils.

These aberrations are (r) spherical, (2) chromatic, (3) astig-matism, (4) curvature of field.

The effects of the two last are much the most important, and will be considered first.

Let O (Fig. a) be the optic centre of the lens, OF the axis of the lens, and if the principal focus, Found PS the curres on the Far better by plane of the plate, F and PS the curres on the PS that the PS that is a far posted to the product of the part of the part of the post of the part of the post of the part of the post of the part of the oval patch of light whose axes are A 72 and A 72 in direc

tions parallel and perpendicular to Fx; A, as before, being the aperiars of the lens.

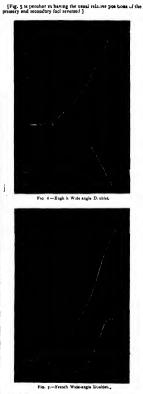

Any formals depending on the actual data of real combinations of lenses, and grimg the values of y, and y, in terms of radu of curvature and refractive indices, &c., of the lenses composing there, would be a very unmanageable thing for the

* I have verife ! th a with a lens of ro-nch focus.

ric. s.-French Portra t. possession (see Figs. 3 to 9). All these lenses except Fig. 5 are by makers reputed to be the best.

NO. 1145, VOL. 44]

The ordinates of these curves are the distances of the pripary and secondary locs from a place through the principal focus at

right angles to the axis of the lens, and are expressed as frac-tions of the focal kingth.

The abacisses are the inclinations (in degrees) of the pencils to

the ax s

Suppose; now, that the plate is placed at a distance e behind

the principal focus, e being half the distance between the fice for direct pencils of the nearest and distant objects.

The worst defined point in the centre of the picture will then be

represented as having a walth A nearly, while at the obliquity

 θ this width becomes $\frac{A}{K} = \frac{\pm y}{100}$ ne rly, according to whether it e

bro. 5.- Proplet

image under consideration is that of the most distant or the

image studer consideration is that of the most distant of the most point.

Hence, unless y is small compared with r, the defination for rays of obliquity 8 will be sensibly worse than in the centre of the plate, and a reference to the curves for y, a d y, shows at glance that that must be the case even at 10 for all the lenses

unless the general standard of the definition is lowered by a large value of s.

As an example of the use of the curves, let us take the rapid

reculirent No. 6, and compare the definition at 20° obliquity with that at the centre, supposing that the nearest object is as a distance of 25F.

This give e = '02F nearly, and at 20' y = - '023F, = + '046 F, hence we have as follows ---

This shows that while the nearest points at this obliquity are represented by long ovals placed as if radiating from the axis, the most distant points become similar but rather smaller ovals with their long axes at right angles to the former, and that the length of the ovals is about twice the diameter of the image formed by the direct pencils

formed by the direct pencis.

In the same way the definition, as far as it depends on astigmatism and cuivature of field, at any obliquity may be found fee any lens for which y, and y, are known Lauriston Hall, September 9

A. MALLOCK.

(To le continued.)

THE KOH-I-NUR-A CRITICISM.

THE true history of the Koh i Nur diamond, if it could be a singularly interesting one. But the historian would have a difficult task. The page task I purpose writing will be devoted to the criticism, possibly the refuting, of some fallacies that hang round the subject, but they will not dem with some other by-torical difficulties has I have not space.

sum with some other on-tonical dimediate that I have not space vent to indicate, but which do not belong to those portions of the history for criticism on which the following pages are designed. The period in the history of the Koh i. Nur I had has attracted the notice of all modern writers on the dismond, and to a degree, I think, somewhat beyond its impostunce, in the first degree. I think, somewhat beyond its importance, is the new or ten manutes during which the French diamond dealer, Tavernier, held in his hand the most important of the Crown pewels of the Empieror Aurungrebe It was a great diamord, and the record Tavernier has handed down in his "Voyage," of its weight, its

The weight of the diamond on the French systems of the second passage of the systems of the second passage of the second pass

in Antwerp, it would be 176 95 troy grains. But none of these are cars: grains. De Boot, on the other hand, in estimating the 140 magnitude in 1755 carst, took the mangelin not at the 5 carst grains of Garcias, but at 5 3568 such grains, taking grains of Garcias, but at 5 3568 such grains, taking carst, the former being one among the several values which this variable suit had in different places.

The 1755 carsts of De Boot would, on the value of the distancest part of the Dutch troy mark, give a weight for the distancest part of the Dutch troy mark, give a weight for the Koba-Nur having been 359 3 iroy grains. It is wery difficult to scarrias in which accuracy the values of the different inst-marks, sometimes of the different continual manufacturing the scarriage of the different continual parts of the different continual parts of the different continual parts of the carling of the 450 manageline and the traditional weight of the complete form. There can be fittle doubt that Le Clince was no error in taking the spothecary weight instead of caral weight intended of the grains of caral weight intended of caral weight intended of the grains of Caral weight intended of caral weight intended of the grains of Caral weight intended of caral weight intended

in error in taking the apothecary weight instead of carat weight in translating the grains of Garcias.

It may be asked, Why devote so much consideration to this cassal statement of De Booch's? The answer is twofold. The astronomer has patiently searched in the records of early observations for any that might indicate the position at a former epoch of a new-found planet, and so, where the silence about an object of historical interest has been scarcely broken through an object of historical interest has been scarcely broken through two or three centures, one tests any observation of the casual wayfarer in the domain of hierature that may perhaps shed a ray of light on it. The other reason is that, if not disposed to resent, one is at least desirous to refute, attack on those who can no longer give their own answer to assailants of a new Can no longer give their own answer to assistants or a new generation, who perhaps may not bring to an investigation the learning or the patient temper of those who have goue from us, and carried great stores of scholarly learning into the silence Whether I am right or wrong in the explanation I have offered of De Boot's conversion of Garcias's 140 mangelins into offered of De Boo's conversion of Garcian's 140 imagellins into 1679 carist, I trust that at any rate I have shown cause for the heard of the Koh-i Nur. It being scarcely probable that two stones should be ce existent of that extraordinary weight." In dealing with another of those coincidences in weight to which alliand was made, and one example, of which has just

which aliusion was made, and one example or which mas just been discussed, we get on the delicate ground of the degree of confidence to be placed in Tavernier's facts and figures, and the not less delicate ground of a theory about the Koh-1 Nur, started by Dr. Ball, before which the other strange vicustitudes and

ny Dr. Ball, before which the other strange vicinstitudes and harbreadth escapes of that old talisman pale into masignificance. We have made sufficient acquaintance with the historic Indian diamond to leave it for a while, in order to introduce that other greater stone which we have designated as the "Great Mogul" Bernler, from personal contact with whom Tavernier no doubt derived much of what had an historical character in his volumes, describes the gift by Emit Jumls, a Persian adventurer of great ability in the service of the King of Goleonda, of a large diamond to the Emperor Shah Jahan, "ee grand diamant que l'on exime sans pareil." It was an appeal to his cupidity, and to a real same parent. It was an appeal to in a capitally, and to a reconnoisseur's passion for precious stones, at a time when the Emir was effecting a change in his allegiance from Golconda to Delhi—in fact, appealing to a new master to induce him to assail the old one.

In 1665, Tavermer, who was no less a contiler than a dealer,

inspect his jewels.

The Emperor, seated on the peacock throne, could see the ceremony that was conducted in a small apartment at the end of Tavernier describes the patient circumspection with the hall. Twernier describes the patient curcumspection with which he was not some and grevel by a Fernian which he was not some and grevel by a Fernian which he was not some and grevel by a Fernian diamond, "Gui set use rose (a rose-cut stone) ronde (rounded These was a small crack at the edge below, and a little face. These was a small crack at the edge below, and a little face which the state of the st

described it.

He proceeds to give his version of its history. It was the stone given by the Emir Jumla to Shah Jaban; but he adds that,

whereas it had then a weight of 900 ratis or 787½ carats, it was worked down by a Venetian diamond-cutter, Hortensio Borgis, till it had only the 280 carats weight above noted. The word egrates is that used; Dr. Bail interprets it as entirely ground down. But, though this is the most rational meaning of this technical word, if would, as Mr. King has remarked, have taken more time than the close of the wonths which intervened between the gift and the edipte of Shah Jahas for the mere gurding flown to have been accommended by the state of would, as Mr King has remarked, have taken more time than the them with sufficient attention and lessure to be able to assure the was that of the thrones which he previously had ample time to inspect. It will be noted he does not say he weighed any of the stones; nor does his doing so seem compatible with his description of the scene

But in another chapter near the end of the same book he giver a brief enumeration of the finest precious stones he had, in his long travels, known The diamond described in the earlier chapter is alluded to now with slight but immaterial variations or corrections as to weight; but lavernier here states that he was allowed to weigh the stone, and he further adds that it had the form of an egg cut through the middle Dr Ball truly notes that this proegg cut through the middle Dr Ball truly notes that this pro-cess may be performed in one of two ways-longutudially, or transversely, and that the Koh-Nur in 1850 represented the difference of form, as I shall explain, was the result of the mutilation to which it was subject." Tayernier's statement that the diamond was "fort heated d'un Tayernier's statement that the diamond was "fort heate d'un

Tavernier's statement that the damond was "fort haste d'un cide" seess, indeed, hardly to accord with any other than a longitudinal section of the egg.

Tavernier appearate to this later chapter—written or edited probably by another hand four or five years after the event of the handling the stane—a role section of the great damond akt.th from memory of a semi-egg shaped stone seen "end on," or of a crows-cut half egg seen from any point of view, but, except for the trace of a small underest fisce in his projection, it was very slightly larger than the length of the Window dismond. is very slightly larger than the length of the Windsor diamond. but in no other dimension does it at all compare with that stone as it was in 1850

as it was in 1050

Then there is the question of weight
Babar's diamond, we have seen, weighed about 8 mishkals, or, in Indian weights, about 330 ratis (gold ratis)
This would correspond to '240 pearl ratis, or may be represented as 224 of the Deccan ratis of Fernshia.

Fernhia.
The diamond Tavernier saw weighed, he said (was he untrily told to, or fid he really weigh it?), 3763 ratio, only half a rail told to or fid he really weigh it?), 3763 ratio, only half a rail those which Babar reckoned by, and his carsts (or cared) must (race Dr. Ball) have been French carsts. Dr. Ball upposes he as contributed to the published das of this tangle of contribution of the state of the stage of contribution of the stage o points out.

points out.

That grattemen assumes from this that Tavernler always employed this casat in his calculations. Such, however, it quite appears to the control of the control of the control of the control of the property of th

tion of what seems to be indicated as his habit to many other instances. He gives the weights of stones he mentions in ratis or mangelins, or in mishkals, and projects to state the equior mangelins, or in multikals, and proceeds to state the equi-valent weight in terms of new caratt, s.a. of the Paras carat; for no Frenchman would designate any carat other than one current in France by such a term. It would be a tedious task to inflict on a reader the minute

detail of calculation and reference to statistical authorities that detail of calculation and reference to statistical authorities that would be involved in a critical study of Tavernier's assertions regarding Indian and other weights, or Dr Ball's incursion into that study. But one fundamental error must be alluded to, that vhiates

But one fundamental error must be alluded to, that whistes the accuracy of Dr. Ball's calculations II is possessed of the ungular belief that, in the sevenie end to castury, Taverner would be the system transitions or usual, which was introduced by the law of May 1812 into France, in temporary substitution for the old livre (posted to man, of 9246 French grains, and its enbdivisions.

It is quite unnecessary to follow the results of this error, for the only interest as regards our inquiry concerns the significance of the 319.5 ratis which Tavernier states the great dismond of Aurungsebe to have weighed. 320 ratis was the Hindon equivalent, in Babar's time, of the 8 mishkals of Babar's diamond, and the Koh I-Nur in 1850 weighed Babar 8

Tavernier says that the 319 5 ratis correspond to 280 French carata (no. carats) Here, then, is a second of those marvellous coincidences in numbers to which we have already made allusion—I may call them impossible coincidences, unless they apply to one and the same diamond

apply to one and the same dismond Dr. Ball sees, apparently, no difficulty in the recurrence of any number of these identical figures as representing the weights of huge diamonds. For his explanation of the matter is that the diamond Tavernier handled was, as the French meris that the diamond Twensier handled was, as the French mer-chant asserted, the stone that Berser mentions is the glft of Emr. Jennia to Shah Jahan; that it did weigh 319-3 ratis, but the state of the fact, to 875 of a caret, whereas Babba's raisu were only 528 of a carat. Dr. Ball's assertion, however, is that this great diamond is the Queen's Koh-i Nur, but that after Nadar Shah's time it had become diminished by successive chipoping state formed out by savely princes, who is succession owned it and sometime of the state of the state of the state of the sumably before it fell into the hands of Ranjit Singh, this great Mogul diamond had shrute in magnitude from its asserted 20c carat to 186 cantar—from the 3163 ratis of Tavernner's exchange to the 320 ratis or Bland's recknoning in a word, it and the state of the 8 mathkait of the Koh-i Nur in 1550. So here is a third connedence that we are called on gravely to access a serious coincidence that we are called on gravely to accept as serious

The only originality, however, involved in this singular view of history, and the way to write it, is the reason assigned for the whitting down of the diamond from the asserted 280 carats the whitting down of the damond from the asserted 200 cannis to 180 cannis Several ingenous persons have indiging before the Kobi-rum from several smaller once tentioral about the the Kobi-rum from several smaller once tentioral about the world, with a fine soon of shape and weight and "water" in the component fragments, and of any historical ground whatever the component fragments, and of any historical ground whatever even suggest the services of the great Kusansh damond in that means, ignorant, apparently of the facts that, live the Kohj-Num.

brownish-yellow hue.

But the coincidences in weight of various phantom diamonds with that which Babar recorded do not come to an end even

with that which Bahar resorded do not some to an end even with this crosmage wonder, as I shall pressurily above Perhaps some one may, in parenthesis, sak what evidence there is for the breaking up of a great diamond, by owners who close to the Kohl-kin with a teason; second didy to their state of the s

Hundoo atone? or if it was, as I have supposed, the Hindoo KohI Nur that Tavernier handled, where was the Great Mogal?
Tavernier awn o recond diamond of the first rank in magan
tode. But there were two great diamonds somewhere—Babar's
and Mir Jumils', or, as I have designanted them, the Koh-Nur
and the Great Mogal. One or other of these Tavernier has
described where was the one he did not see?

and the control of th It is now thirty-five years ago that I suggested the answer upposing, as I did and do, that Tavernier handled the Koh

representing the queen's olabbods, and even lest the distincts Aurungazhe.

The Great Mogul discribed, as he as wit, saming the 'treasures of Aurungazhe.

The Great Mogul discond had been cut by a European cutter distinct to the control of the co autition, probably in a river cea, that the angle between them was no longer quite the true occabedral angle. The facets in general presented an imperfect adamantuse lustre, and appeared slightly rounded, the result, probably, of the imperfect processes employed by the native Hindoo lapidary, especially in very early

times. Even Twernier's drawing radaly indicates three rows of facets, put on in a manner that hardly consists with the fashion of a rowe-cut classmond of European sevinanahaje, or a row-cut classmond of European sevinanahaje. The results of the r

aerchant translated this weight into carats, not as from the old airs of Baber's or even of Akhar's day, but from the pear ratis, of oer other valles, with which he had become sequented in the control of the control of the control of the control of the arts on the ratio of 1, who that he are control from the Tana-yanian, and as drawn from the various samements of equivalent respits it varies from a '2005, in one case 2 750, to 2 757 trop ratio. His method also be pairs at \$\$\text{it had person on the case of the control ratio. The control of the control of the control of the control \$7 tory grains; which should, however, probably have been \$\text{control of the control of the control of the control of the \$\text{control of the control of the control of the control of the control of the \$\text{control of the control of

ig ounces to the mishkal, and the rati of lavernier is entirely lissimilar to any known rati of ancient or modern India. The 319 ratis is readily explained on this hypothesis; and it is eally too large a demand on our credulity to believe that is of he largest diamonds, in the world should be severally of 3196. atis and 320 ratis, though of different units of value, when a impler explanation is able to dispose of the anomaly.

I have said that the marvellous coincidences of weight in nave said that the marvellous coincidences of weight imported nto the Koh i-Nur history do not come to an end with Babar's i mishkals, with Anselm de Boot's 1874 carats, with Tavermer's s mishkals, with America de Boot's 1874 c-rats, with navermers 1194 rats, nor even with Dr Ball's untraculous chipping process, resulting in a reduction of the Great Mogul diamond to the identical weight of the Koh-Nu'r in 1830. The original lamond of Babar had to be accounted for, and its phost had to be also also also another coincidence had to be imported into the ball. So another coincidence had to be imported into se laid. So another conscience had to be imported into the sarature, or rather into the formace Another diamonal had to se found, also will the present weight of the Koh is Nar, and this peak in the laid of the same and the sa

is a large tist distanted with bevelled edges, and in the form of a long rectangle. When Malcolui knew it, it was set in a glorous galaxy of mighty rables. He could therefore have only known is weight from hearsay evidence, and the recorded carais were most likely the echo of those associated with the fame of the most likely the echo of those associated with the fame of the Koh i Nur Now, I have no hesitation in assering this Darya-i Nur to be an old acquaintance of those familiar with Taveriner's pages. Unless two diamonds, flat, bevelled, and of identical dimensions, can be shown in comments. immensions, can be shown to co exist, of above 200 carats weight, the stone known as the Golconda diamond or the Table diamond

the stone known as the Colcount alamond of the labe alamond is no other than the Darya i Nar It happens fortunately to be one of the few stones described by Tavernier to the form and weight of which, as given by him, we can attach complete confidence. He had a lead model made we can attach complete confluence the man a reasonable from it in order to negotiate its sale and he gives its weight as 176) magelias, or 34,5, "de non exam", retream a region at 176 at

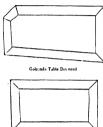

the Golconda: the Darva-i Nur = 10:85.

that is to say, the portion trimmed away was about 15 per cent. The remaining some would thus have a weight of about 26. The remaining some would thus have a weight of about 26. The remaining some would thus have a weight of about 26. The should be about 26. English carsis.

I would be about 26. English carsis.

PHYSICAL CHEMISTRY.

Outlines of General Chemistry. By Wilhelm Ostwald Translated with the Author's sanction by James Walker, D.Sc., Ph.D. Pp. 396. (London: Macmillan and Co, 1800.)

TiAT much may be gained by a judicious use of the methods of the physicist in elucidating chemical phenomena most chemists will admit; and, considering the rapids strictles made of late years in physical chemistry, it seems surprising that so little has been done to give a connected account, suited to the wants of the student, of the main researches in this important field of investigation. Original communications on physical chemistry are on the increase. The chemist has now, in the Zeitsinry to this branch of his science, and during the four years or so of the existence of his journal, its success has testified amply to the ward which it supplies.

Ready access to original memoirs is not, however, the boon of the ordinary student; and, even if it were otherwise, the want of some scheme whereby to systematize his reading and classify his information, much of which is still open to wide difference of opinion, would almost

invariably lead to confusion

The majority of the test-books make little or no attempt at supplying this want. Occasionally a few of the larger chemical treatises spare a few pages to "physical methods," and such test-books as Meyr's "Modernen Theorien" or Murr's "Principles of Chemistry" contain much of the matter classed under physical chemistry.

Yet a comprehensive idea of what has been done in tracing relationships between physical properties and chemical composition and in utilizing physical measurements in investigating chemical change, cannot be obtained from most text-books Indeed, so far as we know, only one is designed to serve this purpose, and that is the "Lehrbuch der Allgemeinen Chemie" of Prof Catwald "Allgemeinen" rather than "Physicalische" "Chemie" has been used as a title for the work; but in the main it-deals with physical chemistry. The book the main it-deals with physical chemistry. The book can be also should be sufficiently and a server at for no other reason than that it furnishes a well-conceived vallabus of the subject-matter of general and physical chemistry, it would be worthy of careful consideration.

The book is divided into two parts-Part I. chemical laws of mass; Part II, chemical laws of energy

The first part opens with stoochometry. The laws of chemical combination, the determination of atomic weights, and a useful summary of the atomic weights, and a useful summary of the atomic weight restinations of the different elements are here given. Then follow sections treating of such of the physical properties of gases, of liquids, of solutions, and of solutions are the chemister must be familiar with, and of the more important relations which have been established between such physical properties and chemical composition.

The section dealing with solutions is noteworthy as containing the first fairly complete statement, in an Eng-

lish text-book, of the facts grouped around the physical theory of solution which has arisen out of a knowledge of osmotic pressure. Part I. closes with chapters on chemical systematics—the choice of atomic weights, the periodic law, the development of the present conception of molecular structure.

In the earlier portions of the second part, thermochemistry, photo-chemistry, and electro-chemistry are discussed. The last takes up the constitution of electrolytes, electric conductivity, and the Arrhenius

dissociation hypothesis

Chemical dynamics and chemical affinity are treated in the last two sections, and afford many illustrations of other use of physical methods in the study of chemical change. In the case of acids competing for the same hase are found instances where physical methods alone hase are found instances where physical methods alone chemical action. In these sections, the exposition of the chemical action. In these sections, the exposition of the chemical action, and of the velocity of chemical law of mass action, and of the velocity of chemical issuipect, the discussion of affinity is here more complete than in the "Lehrbuch," and however unsatisfactory the notion of fixing specific affinity constants be considered, the account set out is the most systematic and plausible yet published.

There is no doubt that the general conception of the book is admirable; it contains much that is new, to the advanced reader it will be refreshing after the time-honoured methods of the ordinary text-books. Yet the general impression which we think will be formed on looking through it, is that the attempt made to compress information into too small a compass has detracted much from its value.

A certain amount of detail is always necessary to incitilgent competension, and in many parts of the book there is too much bald statement to satisfy the reader who approaches the subject for the first time. Manly for this reason it is a question whether the work will answer the expectation of the author that; will "meet end have the requirements of the student who, while not intending not to devote himself to the detailed study of general chemistry, still wishes to follow untelligently the progressor the property of the progression of the progression

The time which has been spent in preparing the chapters on several important topics seems to have been madequate For instance, the molecular volumes of liquids are disposed of in little more than three pages. Kopp's laws are quoted, although not one of them can now be taken as valid, Schiff's inaccurate rule as to the volumes of isomers also finds a place. Instead of apparently settling the question by stating " molecular volumes to be additive magnitudes subject to constitutive influence," little more space would have been occupied in showing how, in different groups of isomers, the volume varies with the constitution. If recent progress on the subject was to be made use of the facts that the effects of molecular weight and constitution cannot be disentangled, that even from the comparison of compounds of similar constitution, definite atomic volumes, determined for the boiling-point, cannot be obtained-that, in short, atomic volumes cannot be regarded as physical constants -ought surely to have been emphasized.

The desire to economize space is probably the cause

of several examples of rather mixed information The following paragraph occurs on p. 104:-

"Ordinary destrolarance acid, for instance, has precisely the sum's properties a Bevoatratine acid; but the compound of both which crystallies from their mixed solutions on exporation—receime acid—has quite a different character. The first-named crystallies analydrous, the last hydrated. The simple acids do not precipitate a solution of calcium sulphate. The compleased that is such difference only occur with solid compounds, race nic acid behaves in solution like a mirrare of the two components.

Seeing that this book is one of the very few in which Vander Waalis's work obtains the prominence which it deserves, and which has been long delayed, it seems a pity that pains have not been taken to make the account securate.

On p 67 the reader is led to infer that θ in Van der Wash's equation is the volume of the molecules; the true value of θ is four times the volume of the molecules, Again, on p 90, it is stated that the equation "is deduced only for the case where the volume of the substance is eight times as large as the magnitude θ ", correctly given, this should be, 'is deduced for cases where the volume is greater than 2θ " is

Admirable as may be the exposition of the theory of solution from the advanced standpoint here taken up, it may rightly be questioned whether the student is fairly treated The physical theory of solution, the dissociation hypothesis, no one knows better than the author, are still strongly contested should the student therefore not have heard a little more of the other side of the question? Particularly objectionable is the application of such terms as Boyle's law, Gay Lussac's law, &c., to solutions In the opening chapters of the book the reader is familiarized with the kinetic theory of gases, he is enabled to form a mental picture of the mechanism which results in the pressure of a gas How he, or, indeed, anyone, can form a similar picture for a solution, when the molecules of the solvent have also to be taken into consideration, it is difficult to imagine. By using for solutions a term such as Boyle's law, which for gases is capable of a perfectly definite interpretation, the real difficulty of the question is ignored, and misconception is almost sure to arise, especially in the case of the beginner

We noticed in passing that, on p 364, polybasic is used for dibbasic, on p 376, $A_0 = k_p^2 k^2$ should be $k_p = k_p^2 k$. Frequently there is no distinction between the type of letters occurring in formulae, and that in which the book is printed Reference in the body of the book to portions of formulae is therefore apt to lead to confusion, and in any case lacks clearness, as may be seen on pp. 879 and 369

The work, from its very title, apart even from the reputation of the author, will no doubt appeal to a large class of readers, as an English text-book of chemissry it is unique. We venture to think, however, that if such points as those indicated were attended to, particularly the question of space, its sphere of usefulness would be materially enlarged

' Physical Society Memours, i. 3, 452 NO. 1146, VOL. 44

UNITED STATES FISH COMMISSION REPORTS

Bulletin of the United States Fish Commission. Vol. VIII for 1888. (Washington, 1890.)

IN 1881 the benate and House of Representatives of the United States of America authorized the public territor to print from time to time any matter furnished to him by the United States. Commissioner of Fish and Fisheries relative to new observations, discoveries, and applications connected with his culture and the fisheries. The printed matter was to be capable of being distributed in parts, the whole was to form an annual volume or Bulletin not exceeding 500 pages, and the edition was to be limited to 5000 copies.

Seven volumes of this important series have since been published, and have been noticed in our pages. They were composed chiefly of translations or republications of articles on fish of fisheries which had appeared in European periodicals or as State documents; extracts from and official correspondence, with statistics of work done; and often of short articles of direct scientific interest on American fish, the whole forming a most valuable, practical encyclopadia of everything relating to the economic study of fish

An eighth volume, dated 1800, but being the Bulletin for 1888, has just been issued from the Washington Press The increased operations of the United States Fish Commission during 1888 have made it possible to devote almost the whole of this volume to the results of the work of the Commission, and it will be found to contain matter of considerable interest. The size of the volume has been slightly enlarged, so as to afford room for larger illustrations.

Of the twelve memoirs or papers contained in this volume, five relate to local collections of fishes Mr Parleton II Bean gives notes on a collection made at Cozumel. Yucatan, sixty species are enumerated; two new species are described and figured. Mr. C. H. Bollman reports on the fishes of Kalamazoo, Calhoun, and Antrim counties in Michigan Mr S A. Forbes contributes a preliminary account of the invertebrate animals inhabiting Lakes Geneva and Mendota, in Wisconsin, and gives some particulars of the fish epidemic in the latter lake in 1884 Mr. C H. Gilbert describes some fish from the lowlands of Georgia Mr D S. Jordan gives a report of explorations made during 1888 in the Alleghany region of Virginia, North Carolina, and Tennessee, and in Western Indiana, with an account of the fishes found in each of the river-basins of those regions.

In a review of the genera and species of Serrandie, by S. Jordan and C. H. Eigenmann, we have an enumeration of all the genera and species belonging to this family found in the waters of America and Europe, together with the synonymy of each, and analytical keys by which the different groups may be distinguished. One hundred and nunteen species are admitted, and thirty-four genera. This memori is illustrated with the plates. Mr. J. W. Collins contributes a paper on improved types of vessels for use in the market fisheries, with some notes on British fishing-steamers, and Mr. W. F. Page gives an account of the most recent methods of hatching fishings.

bility of introducing the mountain mullets of Jamaica (Agonostoma) into some of the Alpine streams of the Southern States; and Mr. R. Rathbun gives a detailed report on the introduction of lobsters to the Pacific shores of the United States.

The two most important contributions to this volume are, however, those by Lieutenant Tanner, "On the Result of the Explorations of the Fishing-grounds of Alaska, Washington Territory, and Oregon during 1888," and by Mr. John A. Ryder, "On the Sturgeons and Sturgeon Industries of the Eastern Coast of the United States,"

Although it had been known for many years that the Pacific coasts of North America were abundantly provided with edible fishes, it was not until 1880 that the exact species of these were correctly determined, the Alaskan cod proving to be the same species as that of the North Atlantic. The absence of large and convenient markets hindered the development of the Pacific coast fisheries; but, with the completion of the railroad system. this state of things has changed, and a strong interest is now being shown in all that relates to the development of the fish industry. This Report affords us the first accurate information that has been obtained respecting most of the fishing-grounds in Alaska. The five banks whose positions were indicated by older surveys-namely. Davidson, Sannakh, Shumagin, Albatross, and Portlock banks-were more thoroughly examined than were the entervening areas, some of which, however, may, upon further examination, prove to contain fishing-banks of equal value, and not inferior in size, to at least the smaller of the banks mentioned

Good fishing was obtained at nearly all localities where rada were made with hand-lines, whether upon defined banks or upon the more level grounds between them, and not set seems natural to infer that the entire submerged plateau erform off Unalashka Island to Fairweather Ground is one mimense fishing-bank, limited upon the outer side only by the abrupt slope, which may be said to begin about the 100-fathom curve

Although the great bulk of this Report relates to the fishing-banks and fishes, yet we get various glimpses of many interesting facts relating to other of the vertebrate and to many of the invertebrate forms met with Off Popolf Island, large masses of sea-urchins, star-fishes, and large Medusæ were found in the scine nets, and the hooks became entangled with fine specimens of sea pens (Pennatula) At the Lighthouse Rocks a landing was in ide, to examine a large rookery of Steller's sea-lion (Eumetopias stellers). Several hundreds of these animals were found crowded together upon a very limited area. As the party landed, the old sca-lions came tumbling down over the rocks in great eagerness to reach the sea; a few. whose retreat was intercepted, were seen to jump from their high positions directly into the water, apparently sustaining no injury from the plunge, although the distance was considerable, especially for such large animals A couple of killer whales (Orca), attracted by the disturbance and the sight of so many seals in the water, came quite close to the rocks, causing the seals to gather nearer the shore, and to cast frightened looks of alarm towards the whales, whose dorsal fins showed not less than four feet above the surface of the water. These rocks

were entirely destitute of vegetation Off Trinity Islands, large quantities of crustaceans, worms, mollusks, echinoderms, and sponges were taken—an especial feature of the hale consisting of over a hundred specimens of a fine large free crinoid. As all these specimens will find their way to the United States National Museum, we may expect soon to have recorded many additions to the manne fauna of the North Pacific.

Mr. John A. Ryder's paper will also be perused with great interest. Having undertaken to report on the sturgeons and sturgeon fisheries of the eastern rivers of the United States, he repaired in May 1888 to Delaware City. which is described as a very important centre of the sturgeon fishery Two species of the genus Acipenser are to be found in the waters along the Atlantic coast of the United States, these are A sturio, 1., and A brevirestris. Le Sueur The former (the common sturgeon) is the only one of any commercial importance at Delaware, as Le Sueur's species is so rare that only five specimens of it were taken by Mr. Ryder, and since the date of its first being described, in 1817, it does not appear to have been until now again recognized Of the other American species, one is the very distinct fresh-water sturgeon of the Lake region, and two others are to be found on the Pacific coast

The embryological data of this memoir have been in a good measure drawn from the author's original investigations, but he has fortunately also given us in addition details from the writings of Balfour, Knoch, Parker, Lograff, and Salensky He found it perfectly practicable to fertilize artificially the sturgeon's roe, and thinks it possible that millions of young sturgeon might be developed in this way He treats in detail of the dermal armature of the sturgeon's body, illustrating this part of his subject by numerous photogravures, describes the organs of locomotion, the lateral line system, the viscera, and lymphatics The sources of the food of this fish and its peculiar habits are next considered, and special information is given about the preparing of the flesh for market. and the manufacture of the caviace. A very useful bibliography of the literature relating to the sturgeon is appended. This memoir is illustrated by twenty-two plates.

THE CATALOGUE OF THE WASHINGTON MEDICAL LIBRARY

Index Catalogue of the Library of the Surgeon-General's Office, US Army Vol XI Phiedronus--Régent Pp 1102 (Washington, 1890)

THE appearance of these very fine folios year by year for the last eleven year: is a very good proof to all lovers of books and collecturus of books in Europe that they have some sympathetic frends in America who have the will and the power to make one at least of their finest libraries well known throughout the world. Its title as the Library of the Surgeon-General's Office may once have sounded little the name of a collection of musty Blue books title together with Mr. J. S. Blulings, which we feet constantly in the monthly publication of the Index Heditury, everyone knows now that it is nothing of the kind, but

one of the first medical libraries, if not the first, in the world, containing much more medical literature than is to be found in the libraries of the richer English corporations, the Royal Colleges of Physicians and Surgeons, or of the more learned and active Societies, such as the Royal Medical and Chururgical Society, or, Indeed, in the British Museum or Bibliothèque Nationale. And though the Washington Library is of comparatively recent date, going back only some thirty years, yet it contains a very fine collection of books both of the fifteenth and sixteenth centuries; and at the same time the great difficulty of the maker of a catalogue to a modern library, viz. the immense mass of the newspaper and periodical literature of to-day, has been fairly faced and overcome. During the past year, 287 periodicals have been added to the list of those that are taken in raising the total number to about 7500, of which at least 3000 are current. The vast aggregate of articles in these are duly catalogued, each under the head of its subject-matter. It is not surprising, therefore, that we should find 80 of these large square folio pages filled in the present volume with entries under the heading Phthisis, 78 under Puerperal Diseases, 67 under Pregnancy, and 56 under Pneumonia. Even as devoted entirely to a lesser matter like the pulse, there are catalogued 150 volumes and 350 articles in periodicals. The care with which the records of the smallest steps in the past history of medicine have been preserved is shown by the accumulation of twenty-five editions of the "Pharmacopæia" of the Royal College of Physicians of London from the years 1657 to 1851. Under such headings as Psychology, we may see the wide range also of the larger subjects embraced in the Library, for the collection under this heading begins with many expositions of Aristotle, and does not neglect Plato, but takes in also the recent books of modern authors, such as the last edition of Herbert Spencer's " Principles of Psychology" and Taine's "De l'Intelligence" The eleventh volume of this magnificent catalogue brings us to within measurable distance of the end; from the analogy of lesser works, in fact, it seems probable it may be completed in three or at most four volumes, and it will then be a great monument among modern catalogues, and in its articles under subject titles form a most valuable dictionary to all who are seeking a clue to the complete historical study of medicine and surgery A T. MYERS.

OUR BOOK SHELF

Dictionary of Political Economy. Edited by R. Inglis Palgrave, F.R S. Part I. Abatement—B (London . Macmillan and Co., 1891.) Abatement-Bede.

THIS is a first instalment of what promises to be a very THIS is a first instalment of what promises to be a very valuable addition to the Linglish library of political economy. The plan of the work is laid down on broad lines, and includes not only articles dealing with strictly economic subjects, and explanations of legal and business terms, but good (though necessarily brief) accounts of historical events bearing on economic history, such as the exhabilament and downful of the additors antionaux? In Paris in 1848, and biographical notices of deceased writers whose life and work has had any connection with the development of economic theory or practice. That the biographical section of the dictionary is conceived in a liberal spirit is sufficiently proved by the fact that the first part, now under review, includes notices of Addison and

Thomas Aquinas; the claim of the former to a place in a dictionary of political economy is based in the main on the fact that he held an official position in the Government of his time as one of the Lords Commissioners of Trade. This rather remote connection with economics may be open to criticism, and it remains to be seen whether Mr. Palgrave will include in his dictionary the honoured names of William Wordsworth and Robert Burns. It is not, however, desirable to say anything in the way of criticism which should tend to narrow the scope of the work. Its interest and vitality depend, to a large degree, on its broad inclusiveness.

The biographical articles are particularly well done, and we would single out that on the late Mr. Bagehot for special commendation It gives not only the dry facts of his career, but presents a living picture of a peculiarly fascinating personality, and also a very just estimate of his place in, and services to, economic literature. Among the prace in, and services to, economic iterature. Among the most important articles in the present installment of the dictionary may be mentioned that on agricultural communities, by Prof. J. S. Nicholson, and that on banks. The former gives an admirable summary of the conditions. of life in existing village communities in Russia and India, and also a digest of the results arrived at by the researches of Sir Henry Maine, Mr Seebohm, and M. de Laveleye, as to the existence of various forms of village communities in the remote past in our own and other countries. The article on banks gives an historical sketch of the development of banking in various countries, contributed by different writers, each with special knowledge of his own portion of the subject. Thus we have brought together within the compass of a few pages an account of the land banks and the Schulze Delitsch credit banks of Germany, the savings banks (trustee and Post-office) of England, and the popular banks of Italy

The names of the contributors to the present volume.

and also those who have promised their assistance in the preparation of the rest of the work, are a guarantee of its high value to all students of social and economical subjects.

South Africa, from Arab Domination to British Rule Edited by R. W. Murray, F R.G S. With Maps, &c. (London: Edward Stanford, 1891.)

ONE of the objects of this book is to bring out the con-ONE of the objects of this book is to bring out the contrast between Portuguese rule in South Africa and the influence exerted by England. The contrast is certainly striking enough; and it is shown most clearly, as in the present work, by a simple statement of historic facts. In the first chapter. Prof. Keane sketches the career of the Portuguese in the various South African regions they have dominated. This is followed by translations they have dominated. This is followed by translations from the "Africa of Dapper, a Dutch writer of the seventeenth century, showing that at that time the Portuguese stationed on the African coasts made no effort to acquire extensive the African coasts made no effort to acquire extensive knowledge of the interior. The editor then records the main facts relating to the Dutch and English settlements in the south, and the recent movements northward to Bechuanaland, Matabeleland, and Mashonaland. Mr. J. W. Ellerton Fry, late of the Royal Observatory, Cape Town, Lieutenant of the British South African Company's expeditionary force, gives an account of what he himself observed during the march into Mashonaland in 1800; and much information with regard to the east coast of Africa at Beira, Pungwe, and the Zambesi is presented in notes from the diary and correspondence of Mr. Neville H. Davia late surveyer and budgerages. dr. Neville H. Davis, late surveyor and hydrographer to the Queensland Government, who, in 1890, accompanied an expedition sent to East Africa to discover whether an expection sent to Last Airica to discover waterner there was any mineral or other wealth in concessions granted by the Morambique Company. The book has not been very systematically planned; but it brings together so many facts which are not readily accessible elsewhere, that it cannot fail to interest readers whose

attention is for any reason especially directed to South Africa. It includes several excellent maps, and two engravings of Cape Town, showing Cape Town as it was in 1668, and as it is in 1891.

LETTERS TO THE EDITOR.

[The Editor does not hold himself responsible for opinsons ex-pressed by his correspondents, Nather can he undertake manuscripts intended for this or any other part of NATURE.

THE MOLECULAR PROCESS IN MAGNETIC

M AGNETIC induction is the name given by Faraday to the act of becoming magnetized, which certain substances perform when they are placed in a magnetic field. A magnetic field is the region near a magnet, or conveying an electric current. Throughto the act of becoming magnetized, which certain near a conductor conveying an electric current out such a region there is what is called magnetic force, and when certain substances are placed in the magnetic field the magnetic force causes them to become magnetized by magnetic induction. An effective way of producing a magnagieste induction. An energive way or producing a mag-netic field is to wind a conducting wire into a coil, and pass a current through the wire. Within the coil we have a region of comparatively strong magnetic force, and when a piece of iron is placed there it may be strongly mag-netized. Not all substances possess this property. Put a piece of wood or stone or copper or silver into the field, and nothing noteworthy happens, but put a piece of iron or nickel or cobalt and at once you find that the piece has become a magnet These three metals, with some of their alloys and compounds, stand out from all other substances and the respect Not only are they capable of magnetic induction—of becoming magnets while exposed to the action of the magnetic field—but when withdrawn from the field they are found to retain a part of the magnetism they acquired Thev all show this property of retentiveness, more or less In some of them this residual magnetism removed without difficulty In others, notably in some removed without uniterity in others, notably in sorted, it is every persistent, and the fact is taken advantage of in the manufacture of permanent magnets, which are simply bars of steel, of proper quality, which have been subjected to the action of a strong magnetic field. Of all substances, soft iron is the most susceptible to the action of the field lt can also, under favourable conditions, retain, when taken out of the field, a very large fraction of the magnetism that has been induced-more than ninetenths—more, indeed, than is retained by steel, but its hold of this residual magnetism is not firm, and for that hold of this resinual magnetism is not firm, and for that reason it will not serve as a material for permanent magnets. My purpose to-night is to give some account of the molecular process through which we may conceive magnetic induction to take place, and of the structure which makes residual magnetism possible.

When a piece of iron or nickel or cobalt is magnetized

by induction, the magnetic state permeates the whole piece. It is not a superficial change of state. Break the piece. It is not a supernous change of state. Dreak the piece into as many fragments as you please, and you will find that every one of these is a magnet. In seeking an explanation of magnetic quality we must penetrate the innermost framework of the substance—we must go to the molecules

the molecules

Now, in a molecular theory of magnetism there are
two possible beginnings. We might suppose, with

Poisson, that each molecule becomes magnetized when
the field begins to act. Or we may adopt the theory of

Weber, which says that the molecules of iron are always
magnets, and that what the field does is to turn them so

Abstract of a Friday Evening Discourse delivered at the Royal Institution on May 22, 1821, by J. A. Ewing, M.A., F.R.S., Professor of Apple Mechanics and Mechanism in the University of Cambridge

NO. 1146. VOL. 447

that they face more or less one way. According to this view, a virgin piece of iron shows no magnetic polarity, not because its molecules are not magnets, but because they lie so thoroughly higgledy-piggledy as regards direc-tion that no greater number point one way than another. But when the magnetic force of the field begins to act, the molecules turn in response to it, and so a prepon-derating number come to face in the direction in which the magnetic force is applied, the result of which is that I may mention at once—it is almost conclusive in itself. When the molecular magnets are all turned to face one when the molecular imagnets are all turner, to save out way, the piece has clearly received as much magnetization as it is capable of Accordingly, if Weber's theory be true, we must expect to find that in a very strong magnetic field a piece of iron or other magnetizable metal becomes saturated, as that it cannot take up any more magnetism, however much the field be strengthened This is just what happens experiments were published a few years ago which put the fact of saturation beyond a doubt, and gave values of the limit to which the intensity of magnetization may be forced.

of magnetization may be forced.
When a piece of iron is put in a magnetic field, we do not find that it becomes saturated unless the field is exceedingly storing. A weak field induces but little magnetism; and if the field be strengthened, more and more magnetism is acquired. This shows that it molecules do not turn with perfect readiness in response. turning is in some way resisted, and this resistance is overcome as the field is strengthened, so that the magnetism of the piece increases step by step. What is the directing force which prevents the molecules from at once yielding to the deflecting influence of the field, and to what is that force due? And again, how comes it that after they have been deflected they return partially, but by no means wholly, to their original places when the field ceases to act?

I think these questions receive a complete and saiisfactory answer when we take account of the forces which the molecules nece sarily exert on one another in consequence of the fact that they are magnets. We shall study the matter by examining the behaviour of groups of little magnets, pivoted like compass needles, so that

of little magnets, pivoted like compass needles, so that each is free to turn except for the constraint which each one suffers on account of the presence of its neighbours, when a piece of iron or steel or nickel or cobalt is mag-netized by means of a field the strength of which is gradually augmented from nothing. We may make the experiment by placing a piece of iron in a coil, and making a current flow in the coil will gradually increased strength, noting at each stage the relation of the induced magnetism to the strength of the field. This relation is observed to be by no means a simple one: it may be observed to de of on means a simple one: it may be represented by a curve (Fig. 1), and an inspection of the curve will show that the process is divisible, broadly, into three tolerably distinct stages in the first stage (a) the magnetism is being acquired but slowly: the molecules, if we accept Weber's theory, are not responding readily—they are rather hard to turn. In the second stage (b) their resistance to turning has to a great extent broken down, and the piece is gaining magnetism fast. In the third stage (c) the rate of increment of magnetism falls off: we are there approaching the condition of satura-tion, though the process is still a good way from being completed.

Further, if we stop at any point of the process, such as Further, it we stop at any point of the process, same as p, and gradually reduce the current in the coil until there is no current, and therefore no magnetic field, we shall get a curve like the dotted line PQ, the height of Q showing the amount of the residual magnetism.

If we make this experiment at a point in the first stage

(a), we shall find, as Lord Rayleigh has shown, little or no residual magnetism : if we make it at any point in the second stage (b), we shall find very much residual magnetism; and if we make it at any point in the third stage (c), we shall find only a little more residual magnetism than we should have found by making the experiment at the end of stage b. That part of the turning of the at the end of stage a. That part of the tanning of the molecules which goes on in stage a contributes nothing to the residual magnetism. That part which goes on in stage c contributes little. But that part of the turning which goes on in stage \(\delta \) contributes very much in some specimens of magnetic metal we find a much

sharper separation of the three stages than in others By applying strain in certain ways it is possible to get the stages very clearly separated. Fig 2, a beautiful instance of that, is taken from a paper by Mr Nagaoka -one of an able band of Japanese workers who are bidding fair to repay the debt that Japan owes for its learning to the West. It shows how a piece of nickel which is under the joint action of pull and twist becomes magnetized in a growing magnetic field. There the first stage is exceptionally prolonged, and the second stage is extraordinarily abrupt.

The bearing of all this on the molecular theory will be evident when we turn to these models, consisting of an assemblage of little prvoted magnets, which may be assemblage of little protect magnets, which may be taken to represent, no doubt in a very crude way, the molecular structure of a magnetizable metal 1 have beer some large model; where the protect magnetia are pieces of sheet steel, some cut mos bent if it bays, others into diamond shapes with pointed mids, other shapes shapes resembling musthrooms or means of a coll of in-ternative to the steel of the shapes when the shapes the magnetic flower or a large wooden frame below the solated wire wound on a large wooden frame below the magnets. Some of these are arranged with the pivots on

a gridiron or lazy-tongs of jointed wooden bais, so that we may readily distort them, and vary the distances of the pivots from one another, to imitate some of the effects of strain in the actual solid. But to display the experior strain in the actual solly in the display the experi-ments to a large audience a lantern model will serve best. In this one the magnets are got by taking to pieces numbers of little pocket compasses The pivots are cemented to a glass plate, through which the light passes in such a way as to project the shadows of the magnets on the screen. The magnetic force is applied by means of two coils, one on either side of the assemblage of magnets and out of the way of the light, which together produce a nearly uniform magnetic field throughout the whole group. You see this when I make manifest the

Fig 1

field in a well-known fashion, by dropping iron filings on

the plate. We shall first put a single pivoted magnet on the plate. We shall first put a single pivoted magnet on the plate is no direction it prefers to any other. As soon as I apply even a very weak field it responds, turning at once into the exact direction of the applied force, for there was nothing (beyond a trifling friction at the pivot) to prevent it from turning

Now try two magnets 1 have cut off the current, so that there is at present no field, but you see at once that the pair has, so to speak, a will of its own I may shake or disturb them as I please, but they insist on taking up a position (Fig. 3) with the north end of one as close as

possible to the south ead of the other If disturbed they return to it; this configuration is highly stable. Watch what happens when the magnetic field acts with gradually growing strength. At first, so long as the field is weak (Fig 4), there is but sittle deflection; but as the deflection (Fig. 4), there is but little deflection; but as the deflection increases at is evident that the stability is being lost, the state is getting more and more critical, until (Fig. 5) the tie that bolds them together seems is to break, and they suddenly turn, with violent swinging, into almost perfect alignment with the magnetic force it. Now I gradually remove the force, and you see that they are Jlones testing, but a stage comes when they awing back, and a

complete removal of the force brings them into the condition with which we began (Fig. 3).
If we were to picture a piece of iron as formed of a vast number of such pairs of molecular magnets, each pair far enough from its neighbours to be practically out of reach of their magnetic influence, we might deduce many of the observed magnetic properties, but not all

Frg. s

In particular, we should not be able to account for so much residual magnetism as is actually found. To get that, the molecules must make new connections when the old ones are broken; their relations are of a kind more complex than the quasi-matrimonial one which the experiment exhibits. Each molecule is a member of a larger

Fig 6

community, and has probably many neighbours close enough to affect its conduct.
We get a better idea of what happens by considering four magnets (Fig. 6). At first, in the absence of deflecting magnetic force, they group themselves in stable pairs—in one of a number of possible combinations. Then—

Fig 7

as in the former case-when magnetic force is applied, As in the former case—wenn magnetic toric is approximately and inferior in the yar at first slightly deflected, in amaner that exactly tallies with what I have called the stage a of the magnetism grocess. Next comes instability. The original ties break up, and the magnets swing violently round; but finding a new possibility of combining (Fig. 7), they take

to that. Finally, as the field is further strengthened, they are drawn into perfect alignment with the applied magnetic force (Fig. 8).

nette force (Fig. 8).
We see the same three stages in a multiform group (Figs. 9, 10, 11). At first, the group, if it is shuffled by any casual disturbance, arranges itself at random in lines that give no resultant polarity (Fig. 9). A weak force produces no more than slight quasi-slastic deflections; a stronger force breaks up the old lines, and forms new ones

Fra &

more favourably inclined to the direction of the force (Fig 10) A very strong force brings about saturation

more favourably inclined to the distribution of the first plant saturation (Fig. 11). They strong force brings about saturation (Fig. 11) an actual piece of from there are multitudes of groups fulfierently directed to begin with—perhaps also favourable the saturation of the first, and so on. Hence, the curve of magnetization does not

consist of perfectly sharp steps, but has the rounded out-lines of Fig. 1.

Notice, again, how the behaviour of these assemblages of elementary magnets agrees with what I have said about residual magnetism. If we stop strengthening the field before the first stage is passed—before any of the magnets have become unstable and have tumbled round into new places—the small deflection simply disappears, and there is no residual effect on the configuration of the group. But if we carry the process far enough to have unstable deflections, the effects of these persist when the force is removed, for the magnets then retain the new

Fig. 10.

grouping into which they have fallen (Fig. 10). And again, the quasi-elastic deflections which go on during the third stage do not add to the residual magnetism.

Fig. 11.

Notice, further, what happens to the group if after applying a magnetic force in one direction and removing it, I begin to apply force in the opposite direction. At first there is little reduction of the residual polarity, till a

stage is reached when instability begins, and then reversal occurs with a rush. We thus find a close imitation of all the features that are actually observed when iron or any of the other magnetic metals is carried through a cyclic magnetizing process (Fig. 12). The effect of any such process is to form a loop in the curve which expresses the relation of the magnetism to the magnetizing force The changes of magnetism always lag behind the changes of magnetizing force This tendency to lag behind is called magnetic hysteresis

We have a manifestation of hysteresis whenever a mag netic metal has its magnetism changed in any manner there meast any magnetism changes in any mainer through changes in the magnetizing force, unless indeed the changes are so minute as to be confined to what I have called the first stage $(a, \operatorname{Fig} 1)$ Residual magnetism is only a particular case of hysteresis

Hysteresis comes in whatever be the character or cause of the magnetic change, provided it involves such deflections on the part of the molecules as make them become unstable. The unstable movements are not reversible with respect to the agent which produces them,

Fig. 12—Cyclic reversal of magnetization in soft iron (AA), and in the same iron when hardened by stretching (as)

that is to say, they are not simply undone step by step as the agent is removed.

We know, on quite independent grounds, that when the magnetism of a piece of iron or steel is reversed, or indeed cyclically altered in any way, some work is spent indeed cyclically attered in any way, some work is spent in performing the operation—energy is being given to the iron at one stage, and is being recovered from it at another; but when the cycle is taken as a whole, there is a net loss, or rather a waste of energy. It may be shown a net loss, or rather a waite of energy. It may be shown that this waite is proportional to the area of the loop in our diagrams. This energy is dissipated; that is to say, it is to say the same of the control of the alternating current, tend to become hot for this very reason; indeed, the loss of energy which happens in it, in consequence of magnetic hysteresis, is a serious draw-back to the efficiency of alternating current systems which the control of alternating current systems of distributing electricity. It is the chief reason why they require much more coal to be burnt, for every unit of electricity sold, than direct-current systems require

The molecular theory shows how this waste of energy When the molecule becomes unstable and tumbles violently over, it oscillates and sets its neigh-bours oscillating, until the oscillations are damped out by the eddy currents of electricity which they generate in the surrounding conducting mass The useful work that can be got from the molecule as it falls over is less than the work that is done in replacing it during the return portion of the cycle. This is a simple mechanical deduction from the fact that the movement has unstable phases

I cannot attempt, in a single lecture, to do more than glance at several places where the molecular theory seems to throw a flood of light on obscure and complicated facts, as soon as we recognize that the constraint of the molecules is due to their inutual action as magnets

It has been known since the time of Gilbert that vibration greatly facilitates the process of magnetic induction. ton greatly actitates the process of magnetic induction. Let a piece of iron be briskly tapped while it lies in the magnetic field, and it is found to take up a large addition of its induced magnetism. Indeed, if we examine the successive stages of the process while the iron is kept vibrating by being tapped, we find that the first stage (a) has orating by 06 ing uppen, we into that the interaction appears that provided in the state of and rapid growth of magnetism almost from the very first. This is intelligible enough. Vibration sets the molecular magnets oscillating, and allows them to break their printive mutual ties and to respond to weak deflecting forms. For a similar reason, vibration should tend to reduce the residue of magnetism which is left when the magnetizing force is removed, and this, too, agrees with the results of observation.

Perhaps the most effective way to show the influence of vibration is to apply a weak magnetizing force first, before tapping If the force is adjusted so that it nearly but not quite reaches the limit of stage (a), a great number of the molecular magnets are, so to speak, hovering on the verge of instability, and when the piece is tapped they go over like a house of cards, and magnetism is acquired with a rush Tapping always has some effect of the same kind, even though there has been no special adjustment of the field.

And other things besides vibration will act in a similar way, precipitating the break-up of molecular groups when the ties are already strained. Change of temperature will sometimes do it, or the application or change of will sometimes do it, or the application or change of mechanical strain Suppose, for instance, that we apply pull to an iron wire while it hangs in a weak magnetic field, by making it carry a weight. The first time that we put on the weight, the magnetism of the wire at once increases, often very greatly, in consequence of the action I have just described (Fig 13) The molecules have been on the verge of turning, and the slight strain caused by the weight is enough to make them go Remove the weight, and there is only a comparatively small change in the magnetism. for the greater part of the molecular turning that was done when the weight was put on is not undone when it is taken off Reapply the weight, and you find again but little change, though there are still traces of the kind of action which the first application brought about to say, there are some groups of molecules which, though they were not broken up in the first application of the weight, yield now, because they have lost the support they then obtained from neighbours that have now entered into new combinations. Indeed, this kind of action may often be traced, always diminishing in amount, during several successive applications and removals of the load (see Fig. 13), and it is only when the process of loading has been many times repeated that the magnetic change brought about by loading is just opposite to the magnetic change brought about by unloading
Whenever, indeed, we are observing the effects of an

NO. 1146, VOL. 44]

alteration of physical condition on the magnetism of iron, we have to distinguish between the primitive effect. which is often very great and is not reversible, and the ultimate effect, which is seen only after the molecular structure has become somewhat settled through many repetitions of the process Experiments on the effects of temperature, of strain, and so forth, have long ago shown this distinction to be exceedingly important: the mole-

cular theory makes it perfectly intelligible.

Further, the theory makes plain another curious result of experiment. When we have loaded and unloaded the from wire many times over, so that the effect is no longer complicated by the primitive action I have just described, we still find that the magnetic changes which occur while we still find that the magnetic changes which occar with the load is being put on are not simply undone, step by step, while the load is being taken off. Let the whole load be divided into several parts, and you will see that the magnetism has two different values, in going up and in coming down, for one and the same intermediate value of the load. The changes of magnetism lag behind the changes of load. in other words, there is hysteresis in the

FIG. 13 -Effects of loading a soft iron wire in a constant field

relation of the magnetism to the load (Fig. 14). This is because some of the molecular groups are every time being broken up during the loading, and re-established during the unloading, and that, as we saw already, involves hysteresis. Consequently, too, each loading and unloading requires the expenditure of a small quantity of energy, which goes to heat the metal.

Moreover, a remarkably interesting conclusion follows This hysteresis, and consequent dissipation of energy, will also happen though there be no magnetization of the cules are magnets. Accordingly, we should expect to find, and experiment confirms this (see Phil. Trans, 1885, p 614), that if the wire is loaded and unloaded, even when no magnetic field acts and there is no magnetism, its physical qualities which are changed by the load will change in a manner involving hysteresis. In particular, the length will be less for the same load during loading than during unloading, so that work may be wasted in every cycle of loads There can be no such thing as perfect elasticity in a magnetizable metal, unless, indeed, range of the strain is so very narrow that none of the molecules tumble through unstable states This may have something to do with the fact, well known to engineers, that numerous repetitions of a straining action, so slight as to be safe enough in itself, have a dangerous effect on the structure of tron or steel

Another thing on which the theory throws light is the phenomenon of time-lag in magnetization. When a piece of iron is put into a steady magnetic field, it does not ack instantly all the magnetism that it will take if time take instantly all the magnetism that it will take it time neitim, which is most noticeable when the field is weak and when the ron is thick. If you will watch the manner in which a group of little magnets breaks up when a magnetic force is applied to it, you will see that the process mention of the processing the process

Fig. 14 -Cycle of loading and unloading

to be It falls over, and then its neighbours, weakened by the loss of its support, follows usut, and gradually the disturbance propagates itself from molecule to molecule throughout the group. In a very thin piece of iron—a fine wire, for instance—there are so many surface molecules, in comparison with the whole number, and consequently so many points which may become origins of disturbance, that the breaking up of the molecular communities is too soon over to allow much of this kind of lagging to be noticed.

Effects of temperature, again, may be interpreted by help of the molecular theory. When ron or nickel or cobalt is heated in a weak magnetic field, its susceptibility to magnetic induction is observed to increase, until a stage is reached, at a rather high temperature, when the magnetic quality vanishes almost suddenly and almost completely.

Fig. 14, from one of Hopkinson's papers, shows what is observed as the temperature of a piece of steel is gradually raised The sudden loss of magnetic quality occurs when the metal has become red-hot, the magnetic quality is recovered when it cools again sufficiently to cease to glow Now, as regards the first effect - the increase of susceptibility with increase of temperature-1 think that is a consequence of two independent effects of heating structure is expanded, so that the molecular centres lie further apart But the freedom with which the molecules obey the direction of any applied magnetic force is in-creased not by that only, but perhaps even more by their being thrown into vibration. When the field is weak, heating consequently assists magnetization, sometimes very greatly, by hastening the passage from stage a to stage b of the magnetizing process. And it is at least a conjecture worth consideration whether the sudden loss of magnetic quality at a higher temperature is not due to the vibrations becoming so violent as to set the molecules spinning, when, of course, their polarity would be of no avail to produce magnetization We know, at all events. that when the change from the magnetic to the nonmagnetic state occurs, there is a profound molecular change, and heat is absorbed which is given out again when the reverse change takes place. In cooling from a red heat, the iron actually extends at the moment when this change takes place (as was shown by Gore), and so much heat is given out that (as Baijett observed) it re-

Fig. 15.—Relation of magnetic inductive capacity to temperature in hard steel (Hopkinson)

glows, becoming bighly red, though, just before the change, it had cooled so far as to be quite dull. [Experiment, exhibiting retraction and re-glow in cooling, shown by means of a long iron wire, heated to redness by the electric current.] In changes which occur in iron assets steel about the imperature of redness are very complex, steel about the imperature of redness are very complex, as the property of the red of the red of the red of the about the red of the red of the red of the red of the about the red of the red of the red of the red of the steel of the red of the red of the red of the red of the steel of the red of the red of the red of the red of the steel of the red of the steel of the red of the steel of the red of the steel of the red of the steel of the red of the steel of the red of the

uon belongs as much to cliemtury as to physics
An interesting illustration of the use of these models
has reached me, only to-day, from New York In a
paper just published in the Electrical World (reprinted
in the Electrican for May 29, 1891) Mr. Arthur Hoopes
supports the theory I have land before you by giving
curves which show the connection, experimentally found
by him, between the resultant polarity of a group of little
by him, between the resultant polarity of a group of little
when the field is applied, removed, reserved, and so on
Ishall draw these curves on the screen, and rough as
they are, in consequence of the limited number of
magnets, you see that they succeed remarkably well in
reproducing the features which we know the curves for
sold-irron to possess

It may, perhaps, be fairly claimed that the models whose behaviour we have been considering have a wider application in physics than merely to elucidate magnetic processes. The molecules of bodies may have polarity which is not magnetic at all—polarity, for instance, due to static electrification—under which they growth themselves in

stable forms, so that energy is dissipated whenever thate are broken up and restranged. When we straw a solid body beyond the restranged and the strawn a solid body beyond the restraining, as it were, internal friction. What is this internal friction due to but the breaking and making of molecular ties? And if internal friction, why not also the surface friction which causes work to be spent when one body rubs upon another? In a highly suggestive passage of one of his writings, 'Clerk Maxwell threw out the hint that many of the irreversible processes of physics are due to the breaking up and reconstruction, and, in studying them to engit, I think we may claim to have been going a step or two forward where that great leader pointed the way.

THE SUN'S MOTION IN SPACE

SCIENCE needed two thousand years to disentangle the earth's orbital movement from the revolutions of the other planets, and the incomparably more arduous problem of disninguishing the solar share in the confused multitude of stellar displacements first presented itself as possibly tractable little more than a century ago. In the lack for it as yet of a definite solution there is, then, no ground for surprise, but much for satisfaction in the large measure of success attending the strenuous attacks of which it has so often been made the object

Approximately correct knowledge as to the direction and velocity of the sun's translation is indispensible to a profitable study of steeral construction, but apart from some acquaintence with the nature of sidereal construction, it is difficult, if not impossible, of attainment One, in fact, presuppose the other. To separate a common fact, presuppose the other. To separate a common the sphere of three or four thousand stars is a task practicable only under certain conditions. To begin with, the proper motions investigated must be established with general exactivide. The errors inevitably affecting them must be such as pretty nearly, in the total upslay, to neutralize one another. For should they run mainly constituted to the control of the contro

Besides this obstacle to be overcome, there is another which it will soon be possible to evade. Hitherto, inquiries into the solar movement have been hampered by the necessity for preliminary assumptions of some lists, are highly insecure; and any fahre reared upon them must be considered to stand upon trescherous ground, and the second of the second

"Eacyc. Brit.," Art. "Constitution of Bodies" NO. I146, VOL. 44 tangential component, with the solar movement; and since complete knowledge of it, in a sufficient number cases, in rapid becoming accessible, while knowledge of cases, in rapid becoming accessible, while knowledge of cases, in rapid becoming accessible, while knowledge of report motions to the case of the proper motions by that of motions in line of sight is obvious and immediate. And the admirable work carried on at Pottdam during the last three years will soon afford the means of doing so in the first, if only a preliminary investigation of the solar translation based upon measure-

ments of photographed stellar spectra. The difficulties, then, caused either by inaccuracies in star-catalogues or by ignorance of star-distances, may be overcome; but there is a third, impossible at present to be surmounted, and not without magaving to be passed system through space start with an hypothesis most unlikely to be true. The method uniformly adopted in them—and no other is available—is to treat the indirect motions of the stars (their so-called motion peculiarum) as pursued indifferently in all directions. The steady science of probabilities in presumed to be tolar motion vausally transferred to them in proportions varying with their remoteness in space, and their situations on the sphere if this presumption be in any degree baseless, the result of the inquiry is gre lands falsified. Unleast the sphere is the mother on the whole, their discussion may easily be as frutiless as that of observations tainted with systematic errors. It is scarcely, however, doubtful that law, and not chance, governs the sidereal revolutions. The point open to question is whether the workings of grand sum-total of results which, from the geometrical side, may justifiably be regarded as casual.

The search for evidence of a general plan in the wanderings of the stars over the face of the sky has so far proved fruitless. Local concert can be traced, but no widely-diffused preference for one direction over any other makes itself definitely felt. Some regard, neverheless, ware be paid by them to the plane of the Milky Way, since it is altogether incredible that the actual conmethod of their revolutions.

The apparent anomaly vanishes upon the consideration of the profundates of space and time in which the fundamental design of the sidereal universe lies buried. Its composition out of an indefinite number of partial systems is more than probable; but the inconceivable lessurelines is more than probable; but the inconceivable lessurelines is more than probable; but the inconceivable lessurelines with which their mutual relations develop renders the harmony of those relations mappreciable by short-lived of a subordinate kind; they are indexes simply to the mechanism of particular aggregations, and have no definable connection with the mechanism of the hole. No considerable error may then be involved in treating them, for purposes of calculation, as indifferently directed; and the chief of our system relative to its more mimediate displacement of our system relative to its more mimediate displacement of our system relative to its more mimediate shoped for until sidereal astronomy has reached another saduum of progress.

Unless, mdeed, effect should be given to Clerk Maxwell's suggestion for derwing the absolute longitude of the solar apex from observations of the eclipses of the solar apex from observations of the eclipses of pupter's satellites (Proc. Roy. Soc., vol. xxx. p. 129). But this is far from likely. In the first place, the revent anything like the required accuracy. In the second place, there is no certainty that the postulated phanomena have any real existence. If, however, it be safe to assume that the solar system, cutting its way through space, virtually rauses an etheral counter-current, and if

it be further granted that light travels faster world than acquiests such a current, then indeed it becomes speculatively possible, through slight alternate accelerations and retardations of eclipses taking place respectively ahead of and in the wake of the sun, to determine his absolute path in space as projected upon the ecliptic. That is to say, the longitude of the apex could be deduced together with the resolved part of the solar velocity, the latitude of the apex, as well as the component of velocity perpendicular to the plane of the ecliptic, remanning, however,

The beaten track, meanwhile, has conducted two recent inquirers to results of some interest. The chief aim of each was the detection of systematic peculiarities in the motions of stellar assemblages after the subtraction from them of their common perspective element By varying the materials and method of analysis, Prof Lewis Boss, Director of the Albany Observatory, hopes that correspond-ing variations in the upshot may betray a significant character. Thus, if stars selected on different principles give notably and consistently different results, the cause of the difference may with some show of reason be supof the dimetricle may write some now to reason to sup-posed to reside in specialities of movement appertanting to the several groups. Prof. Boss broke ground in this direction by investigating 284, proper motions, few of which had been similarly employed before (Astr. Jour., No. 213). They were all taken from an equatorial sone 4° 20′ in breadth, with a mean declination of +3°, observed at Albany for the catalogue of the Astronomische Gesellschaft, and furnished data accordingly for a virtually independent research of a somewhat distinctive kind. was carried out to three separate conclusions. Setting aside five stars with secular movements ranging above 100, Prof. 100s divided the 279 left available into two sets—one of 135 stars brighter, the other of 144 stars fainter, than the eighth magnitude. The first collection gave for the goal of solar translation a point about 4° north of a Lyra, in R.A. 280°, Decl. + 43°, the second, north of a Lyrze, in R A. 280°, Decl. + 43°, the second, one some thirty-seven minutes of time to the west of 8 Cygni, in R A 286°, Decl + 45°. For a third and final solution, twenty-six stars moving 40"-100" were rejected, and the remaining 253 classed in a single series upshot of their discussion was to shift the apex of move-ment to R.A 289°, Decl. + 51° So far as the difference from the previous pair of results is capable of interpretafrom the previous pair or results is capacite or interpreta-tion, it would seem to imply a predominant set towards the north-east of the twenty-six swifter motions subse-quently dismissed as prejudical, but in truth the data employed were not accurate enough to warrant so definite employed were not accurate enough to warrant as definite an inference. The Albany proper motions, as Prof. Boss was careful to explain, depend for the most part upon the right ascensions of Bessel's and Lalande's zones, and are hence subject to large errors. Their study must be

regarded as suggestive rather than declaive.

A better quality and a larger quantity of material was disposed of by the latest and perhaps the most laborous investigator of this intricate problem. M. Oscar Stumpe, of Bonn (Matr. Nack, Nos. 2995, 3200) took has start, to the number of 1054, from various quarters, if testing, however, the movement attributed to each of not testing, however, the movement attributed to each of not less than 10° a century. This he fixed as the limit of secure determination, unless for stars observed with exceptional constancy and care. His discussion of them is instructive in more ways than one. Adopting the additional control of the secure of the secure of the security of the sec

M. Stumpe's intrepid industry was further shown in his disregard of customary "scamping" subterfuges. Expedients for abbreviation vainly spread their allurements;

every one of his 2108 equations was separately and resolutely solved. A more important innovation was his substitution of proper motion for magnitude as a criterion of remoteness. Dividing his stars on this principle into four groups, he obtained an apex for the sun's translation corresponding to each as follows—

Group	Number of	Proper motion	Apex				
1	included stars	0 16 to 0 32	RA.	287 4	Decl.	+ 42°	
11	340	0 32 to 0 64	,,	279'7	**	40'5	
III	. 105 .	0 64 to 1'28	,,	287 9	.,	32 1	
IV.	. 58	I 28 and unward	g	285.5		30.4	

Here, again, we find a marked and progressive descent of the apex towards the equator with the increasing swiftness of the objects serving for its determination, swiftness of the objects serving for its determination, the most genume position, because the one least affected by stellar individualities of movement. By nearly all recent investigations, moreover, the solar print de mire has been placed considerably further to the east and their predecessors; so that the constellation Lyra may now be said to have a stronger claim than Hercules to middle it; and the necessity has almost disappeared for include it; and the necessity has almost disappeared for needing galectic plane.

From both the Albany and the Bonn discussions, there

From both the Albany and the Bonn discussions, there emerged with singular clearness a highly significant reliation. The mean magnitudes of the two groups into which Prof. Boss divided his 279 stars, were respectively 65 and 85°. In lost environment of 1979 stars, were respectively 66 and 86°, the corresponding mean proper motions 21° of and 80°. In lother words, as see of stars on the whole larger sum-toral of apparent displacement. And that this larger sum-toral of apparent displacement. And that this approximate equality of mean distance was made manifest by the further circumstance that the secular journey of the sun proved to subtend nearly the same angle whichever of the groups was made the standpoint for its survey, lodeed, the fainter collection actually gave the larger magnetic stars of the groups was made the standpoint for its survey, lodeed, the fainter collection actually gave the larger magnetic stars of the superior support of the groups and made fair and applied the support of the groups and so fair and applied to the earth than the much brighter ones considered apart.

"Å result similar in character was reached by M Stumpe. Between the mobility of his star groups, and the values derived from them for the angular movement of the sun, the conforming proved so close as materially to strengthen the inference that apparent movement to strengthen the inference that apparent movement classified stars scened, on the contrary, quite independent of their mobility. Indeed, its changes tended in an opposite direction. The mean magnitude of the slowest group was 60, of the swiftest 65, of the intermediate pair 67 and 671. And these are not isolated apparent of the contrary of

What meaning can we attribute to them? Uncrutically considered, the yearn to assert two things, one reasonable, the other palpably absurd. The first—that the average angular velocity of the stars varies inversely to double; the account—that their average apparent lustre to double; the account—that their average apparent lustre than anothing to do with greater or less remoteness—few will be disposed to admit. But, in order to interpret ruly, well-ascentamed if unexpected relationships, we must remember that the sensibly moving stars used a multitude sensibly fixed; and that the proportion of stanonary to travelling stars rises rapidly with descent down the scale of magnitude. Hence a mean

struck in disregard of the zeros, is totally misleading; while the account is no sooner made enhanstive than its anomalous character becomes largely modified. Yet in does not wholly disappear. There is some warrant in a preponderance, among suns endowed with high systiad speed, of small, or slightly luminous, over powerfully radiative bodies. Why this should be so, it would be fulls, even by conjecture, to attempt to the PLEEKE.

A M. CLERKS

NOTES

THE respect in which science is held in Germany was strikingly displayed on Tuesday, when Prof Virchow celebrated his seventieth birthday The occasion was regarded as one of national importance, and much honour was done to the silves. tigator who, in the course of his great career, has given a fresh impetus to so many departments of research. In the morning, congratulations were offered to him in the large hall of the Kaiserhof Hotel, Berlin. The room was crowded with professors, academicians, and men of science from all parts of Europe, and on a long table were innumerable presents, medals, diplomas, and addresses. Short speeches were delivered on behalf of a series of deputations, the first of which was headed by Dr. Bartsch, one of the chief officials of the Ministry deputation, consisting of the professors of the Medical Faculty of the University of Berlin, and headed by Prof Hirsch, the Dean, was followed by another from the Berlin Academy of Science, for which Prof von Helmholtz spoke Forckenbeck, the Burgomaster of Berlin, heading a deputation from the Municipality of the capital, presented Prof Virchow with the freedom of the city, referring gratefully to all that he had done to improve the health of the community. An address and medal, sent by English scientific bodies, were presented by Dr Simon and Mr Horsley, and then came congratulatory addresses from the Medical Faculties of many foreign cities, including Amsterdam, Brussels, Stockholm, St l'etersburg, Moscow, Psvia, and Tokio | the Virchow gold medal, for which contributions had been sent from all sections of the medical world, was presented by Prof Waldeyer Frau Virchow received a silver replica, and bronze copies were given to the other members of the family and to the scientific bodies which had subscribed for the medal. In the afternoon, a second meeting was held in the large hall of the Pathological Institute, where, as the Berlin correspondent of the /tmes says, "an almost endless procession of learned bodies and other corporations, presenting gifts and addresses, defiled before Prof. Virchow" The day's proceedings lasted from 10 a m. to 4 p.m., but it was noted, we are glad to say, that Prof Virchow "seemed in no way fatigued by his exertions." More speeches were delivered in the evening, when a "Commers," or reunion. of his friends and admirers was held in Kroll's Theatre

This ordinary general meeting of the Institution of Mechanical Engineers will be held on Wedinesday sering, Cotober 26, and Thurnday evening, October 29, at 25 Great George Street, Westimmater. The chair will be taken at half past seven p.m. on each evening by the President, Mr. Joseph Tominnoo. The ballot lists for the election of new members, associates, and graduates having been preriously opened by the Council, the masse of those elected will be announced to the meeting. The nomination of officers for election at the next annual general meeting will the place. The following papers will be read and discussed, as far as time permats:—On some details in the construction of modern Lancashire boller, by Mr. Sanuel Boswell (Wedensday); First Report to the Alloys Research Coumittees, by Prof. W. C. Robert-Austen, C. B., F. R. S. (Thursday).

THE anniversary meeting of the Mineralogical Society will be held in the apartments of the Geological Society, Burlington House, on Tuesday, November 10, at 8 p m.

THE International Congress of Analytical Chemists and Microscopists met at Vienna on October 12 and 13. The subject discussed was the adulteration of food-stuffs.

GREAT preparations are being made for the meeting of the Australasua Association for the Advancement of Seence whole is to be held at Hobart, Tasmana, in January next. It is expected that the meeting will be most successful. The members of the Royal Society of Tasmana are congentuating economist, proposes to attend the meeting and to read a paper. His Excellency Sir R. G. C. Hamilton, who will preside, tried some time ago to secure the presence of Prof. Huxley also, Drof. Huxley replied that he had pleasant recollections of Tasmana as it was forty three years ago, and it would have uncreased the presence of the pre

ONE of the last surviving pupils of Dalton died at Bolton on October 6. Mr William B, Watson was born at Bolton in January 1812, and educated at the local grammar-school. He afterwards studied for some years under Dalton at Manchester, and became so devoted to his teacher that he was chosen to help in the nursing of Dr. Dalton during the illness following his first paralytic seizure Mr. Watson also assisted in many of Dalton's researches, and is mentioned by name in his papers in the Philosophical Transactions on the composition of the atmosphere as "an ingenious pupil of mine, Mr William Barnett Watson " Mr Watson had a wonderful store of anecdotes about his old master, and used to speak with pride of the great care he took in all his work. As an instance may be mentioned the pains he took to compensate for his colourblindness. Dalton used to say that the bloom on a maiden's cheek and the colour of a faded green table-cloth seemed to him one and the same, and that he could only distinguish between the fruit and leaves on an apple-tree by their difference in shape Dalton had a book containing different colours of floss silk. and below these he carefully noted the names given to them by non-colour blind people, adding what the colour appeared to him to be Careful methods such as these enabled him generally to give an accurate description of the colour of a precipitate. Mr Watson carried on, together with his elder brother, Mr II H. Watson, a very extensive practice as an analytical chemist, and was much consulted in legal and commercial cases

Tits death of Mr. Charles Smith Wilkinson, the Government Geologuts of New South Wales, will be fit as a great loss, especially in his own colony. He esthusiasm in the cause of geological science, he acteasure knowledge of the geological features of Eastern Australia, and his admirable personal eastern Australia, and his eastern Australia eastern and remedient of his Society of New South Wales. And presented that Society he years 1853 and 1854. His east presented the Society events, on the 26th of August, was unconnect to the Society on the evening of the same day.

La Nature amounces the death of Prof. Edonard Lucas, who presided over the Sections of Mathematics and Astronomy at the recent meeting, at Marseilles, of the French Association for the Advancement of Science A pile of plates fell one day after disner while he was at Marseilles, and he happened to be struck in the cheek by a fragment of the broken earthenware. The hunt became more and more troublesome, and after his return

to Paris he died of erysipelas. M. Lucas was forty-nine years of age. He was a brilliant lecturer, and the author of several valuable books, the most important of which is his "Réeréations Mathématiques."

APPLICATION has been made for 20,000 square feet of space for the electrical duplay from Great Britan at the "World's Fair" at Chicago. Electricity, the new weekly journal publanded at Chicago, remarks that this application should "state rest all doubts in regard to the extent of the exhibit to be made by British manufacturers of electrical apparatius"

MR. C. E KELWAY IS now showing at the Royal Naval Exhibition an invention which promises to be of great practical value. It consists of an apparatus for manne and general electrical signalling A number of electric incandescent lamps are placed in a suitable frame, from which insulated wires are led to a key-board, similar to those used in typewriters, or compound-switch A key is appropriated for each letter of the alphabet and for numerals. On this key being de pressed the electric current is switched on to the lamps representing the corresponding letter, which is at once shown to the observer. On the pressure being removed the lights disappear, and the next letter, or numeral, is in like manner shown, the words being spelt out at a rate more quickly than by the Morse system Mr Kelway claims that the applications to which this invention can be put are numerous. It might, he thinks, be of great service in naval tactics, and prove invaluable for military pur poses He also points out that it would enable mercantile vessels to communicate readily with each other and with the shore

A CORRESPONDENT asks whether there are any firms which supply magic lantern slides dealing with geological subjects

THE marine laboratory of biology and zoology, which is to be instituted at Bergen next year, will be open to any foreign in vestigators who may desire to study the marine fauna of that part of Scandinavia.

THE complete list of subscribers to the memorals to Bashog Berkeley, which has just been susued, contains the names of Profs Husley and Tyndall, in company with the Archbashog of Dublin and a number of biblogs and deans. Mr. Gladstone and Mr. Balfour meet together in the same list. The memoral is a beautiful resumbent figure by Mr Bruce Joy, R A, which has been placed in Cloyne Cathedral. The inscription to be placed on the mounteent has our by these announced.

THE Sociedad Cientifica "Antonio Alrate," of Mexico, who have lately moved atto new quarters, have just resolved to throw open their scientific library to the general public They are appealing on this ground to all foreign professors and scientific authors to send copies of their works to the library

THE Engineers' and Architects' Institute of Vienna have resolved to petition the Austrian Government that engineer attaches should in future be appointed to the embassies and legations in London, Berlin, Paris, St. Petersburg, Rome Washington, and to one Oriental city to be hereafter selected.

THE Royal Hortrealtural Society has issued a list of fruits which might be profitably cultivated by cottagers and small farmers in this country. The last (to which are added notes on planting, prusing, and manuring) ought to be widely distributed it contains all the information that is really necessary for the development of a most important industry.

ACCORDING to a telegram sent from San Francisco, a severe share of earthquake was felt there on October II, but no damage was done. At Napa, Californas, where a heavy shapk was seperienced, the chunneys were thrown to the ground, and several buildings were shattered. The State Instane Asylmin is reported to have been damaged, fistures being made in the walls. The Inmutes were seized with naine.

NO. 1146, VOL. 44

Wit take from La Nature of the 3rd inst, the following particulars respecting the destructive cyclone which visited Martinique on the 28th of August last The curve of a Richard barograph shows that the barometer commenced to fall about 2 pm , when it stood at 20 02 inches, while between 7 and 8 p.m u fell from 20 72 inches to 28 70 inches. wind at this time, too, reached its greatest violence, and continued with hurricane force for several hours, passing alternately from N.E. to South The recovery of the barometric pressure was equally rapid, the reading being about 20 70 inches before 10 p.m. M Sully, of Saint Pierre, writes that the lightning was constant, with varying intensity before and after the passage of the centre. The sound of the thunder was scarcely perceptible. owing to the howling of the wind and the noise caused by the falling roofs and houses. Globular lightning was seen on all sides during the hurricane, the country folks speak of globes of fire which traversed the air for several minutes, and burst about two feet above the ground. All the towns and villages were greatly damaged, the crops destroyed, and that usually verdant country presented the appearance of the depth of the most severe winter. The deaths are said to be 420 in number.

In the review of September in the U.S. Tilot Chart, it is pointed out that the month was unusually vorinny on the North Atlantic, as indicated by the storm tracks plotted on the thart. Two of these tracks, however, represent August storms, one of them being the track of the Martinique hurricane, and another the track of the hurricane that passed east of Hermuda on August 27. The Martinique hurricane, it appears, moved west-north-west along a somewhat irregular track, crossing over Puerto Rico, Turk's Island, Crooked Island, and lower Florids, finally dying out in the north-eastern Gulf. This univual course makes it of special interest, and its failure to recurve seems to have been due, possibly, to the opposition of the Bernuda hurricane, and amaner similar to the deflection towards Vera Cruot of the Cuban hurricane of September 1888. The Bernuda hurricane appears to have originated about 300 miles S. W. of the Cape Verde Islands on August 19

This correspondent of the Time, at Alexandra telegraphed on Ceoher 11 than three colorsal statuse, not feet high, of rose gannin, had just been found at Aboukir, a few fest below the unifice. The discovery was made from indications firmshed to the Government by a local investigator, Diannos Pasha. The first two represent in one group Rameses II and Queen Hestimars seated on the same throne. This is unique among Legytian satistic. The third status represents Rameses standing wingstin military attire, a sceptre in this hand and a crown upon his head. Both here hereophyphic inscriptions, and both have been thrown from their pedestals face downwards. Their site is on the monent Cape Tephynum, near: the remains of the Temple of Venus at Asinoe. Relies of the early Christians have been found in the same locality of the contraction.

We learn from the Breykon Hersids that a discovery full of merest to archaeologist has been made in Sausse. During some excavations near the depot of the Artillery Volunteers at South-ore, Lewes, the workmen uncovered as many at tensylvelght skeletons. They were all burned close to the vurface, and within an area of about 13 feet by 50 feet. As three were skeletons of women as well as of men, it is concluded that the save was not that of a battle-field, but 10' a place of burnal. A similar find was made in 1850 at Mailing Hill, which is not first was not that of which were accompanied by a large number of weapons and ornaments, the product of the product of

MR CLEMENT L. WALKER, while carrying on geological work in South-Western New Mexico, has also been pursuing archicological researches in that most interesting region during the last two years He proposes to publish a detailed account of his investigations, and in the meantime he briefly records some of them in the August number of the American Naturalist, On the east, west, and middle branches of the Gila River, in the Mogolion Mountains, there is an extremely rough, wild, and broken tract, and here, in the rugged eliffs, are found great numbers of ancient cliff-dwellings. Mr. Webster devoted considerable time to the study of these dwellings, making plans and sketches, and conving the drawings of many of the more interesting and extensive hieroglyphics painted on the rocks One of these ancient pueblos of the ehff-dwellers is situated in a lofty cliff which forms the side of a deep, narrow canon extending out from the west branch of the Gila. This eliffdwellers' village is in a fine state of preservation, and consists of upwards of twenty-eight rooms. Among the relics obtained in the rooms were specimens of several kinds of cloth, all made from the fibre of the Spanish dagger, matting of bear-grass willow work, sandals, cords of various sizes, feather-work, a ball and large skein of twine of the same material as the cloth, human and animal bones, stone utensils, great quantities of corn-cobs, corn, squash or pumpkin rinds, seeds and stems, corn-husks, beans, gourds, pottery, braided human hair of a brown colour, &c , and last, but by no means least, a perfectly preserved cliff dweller mummy. This was a mummy of a small child, with soft brown hair, similar to that found braided, only finer. It was closely wrapped in a considerable amount of two varieties of coarse cloth, woven from the fibre of the Spanish dagger, then wrapped in a large nicely-woven mat of bear grass, and tied on by cords of the same material as the cloth to a small curiously-shaped board of cotton-wood

576

SOME fine caves have lately been discovered near Southport. Tasmania At the meeting of the Royal Society of Tasmania in June, an account of them was given by Mr. Morton, who had visited them They are situated about four miles from Ida Bay, and a fairly good road leads to them The entrance is through a limestone formation. A strong stream flows along the floor of the chambers. The first chamber reached by Mr Morton and those who accompanied him showed some fine stalactites, and along the floor some tine stalagmites were seen. On the lights carried by the party being extinguished, the ceiling and sides of the caves seemed studded with diamonds, an effect due to millions of glow-worms hanging to the sides of the walls and from the ceilings Further on, several chambers were explored, each revealing grander sights The time at disposal being limited, the party had to return after traversing a distance of about threequarters of a mile, but from what was observed the caves evidently extended a distance of three or four miles. The only living creatures seen were the glow-worms. These caves, under proper supervision, should become, Mr. Morton thinks, one of the great attractions of the south of Tasmania.

In the Quarterly Statement of the Palestine Exploration Fund. it is announced that the first volume of the "Survey of Eastern Palestine," by Major Conder, has been issued to subscribers It is accompanied by a map of the portion of country surveyed, special plans, and upwards of 350 drawings of ruins, tombs, dolmens, stone circles, inscriptions, &c. It is also announced that the new map of Palestine, so long in hand, is now ready This map represents both sides of the Jordan, and extends from Baalbek in the north, to Kadesh Barnea in the south.

MR. E. R. MORSE contributes to the October number of the Engineering Magasine, a periodical issued at New York, an interesting paper on marble quarrying in the United States.

cemeteries and in buildings has become very extensive. Various foreign marbles, such as the African Red, Belgium Black, and Mexican Onyx, are employed in the interior decoration of buildings . but only Italian marble can be said to come really into competition with the American product, and the importation of this stone into the United States amounts only to about one-sixth of the value of the marble produced and sold at home. The quarrying of marble is practically limited at present to Tennessee, Georgia, Maryland, New York, Massachusetts, and Vermont Large and valuable deposits may exist elsewhere, but the expense of testing deposits is so great, and the chances that the product of new quarries may prove unsaleable are so numerous, that Mr Morse thinks that new marble fields are not likely to be developed soon

THE "basking shark" (Selache maxima, L) is apparently no very uncommon visitor in New Zealand waters. In the new volume of the Transactions and Proceedings of the New Zealand Institute, Mr T. F Cheeseman, Curator of the Auckland Museum, describes a specimen, over 34 feet long, which was stranded near the mouth of the Wade River. Mr. R. H. Shakspere, of Whangaparaoa, who saw the specimen very shortly after it was stranded, has informed Mr. Cheeseman that every spring several individuals of the same species can be seen near the entrance of the Wade River, and along the shores of Whangaparaoa Peninsula He believes that they visit these localities in search of their food, which he thinks is composed of small Meduse and other pelagic organisms. They can be easily recognized from their habit of swimming on the surface of the water, a portion of the back and the huge dorsal fin being usually exposed It is from this circumstance, taken with the fact that their motions are very often slow and sluggish, that they have received the name of the "basking shark" They are easily approached and harpooned, and on the west coast of Ireland as many as five hundred have been taken in a single season The liver often weighs as much as two tons, yielding six to eight barrels of oil. A few years ago, when sharks' oil was of greater value than it is at present, the oil from a single full-sized specimen would often realize from £40 to £50.

AT the meeting of the Linnean Society of New South Wales, on June 29, Mr. Froggatt exhibited some living beetles (fam. Curcultonida), which afford a good example of protective coloration They were found at Wellington, N S.W., on the trunks of Kurrajong trees (Sterculia), the bark of which they resemble so closely in tint and general appearance that it was quite by accident Mr Froggatt first recognized their true

MESSRS GAUTHIER-VILLARS have sent us the "Annuaire" for 1891 of the Municipal Observatory of Montsouris. It contains, as usual, a great mass of carefully selected and well arranged information We may especially note a collection of old meteorological observations made at Paris, and the following papers Parisian climatology, by M Léon Deseroix; chemical analysis of the air and of waters, by M Albert Lévy; thirteenth memoir on organic dust in the air and in waters, by Dr. Miquel.

MESSES G. L ENGLISH AND CO, New York, have found it necessary to use a supplement to the catalogue of minerals which they published in June 1890 So great has been the demand for minerals that they had three collectors at work during the summer-one in Europe, another in the southwestern part of the United States and in Mexico, and a third in Colorado.

THE new number of the Journal of Anatomy and Physiology opens with some valuable notes by Dr. R. Havelock Charles, Within recent years the use of American marble both in on the craniometry of some of the outcaste tribes of the THE Department of Public Instruction in New South Wales as issued a accord edition of "Wattles and Wattle-Barks," by J. H Maiden. It appears as No 6 of the Technical Education Series. The pamphle is intended to supply Australana farmers, actually a supply and the supply Australana farmers, regard to the value of wattles. According to the author, the demand for good waitle-bark becomes greater every years, and the supply does not cope with it "The word" wattle," we move the supply does not cope with it "The word" wattle," we may note, has become in Australia particulally synonymous with

AN interesting experiment has been lately made by M Chabry, of the Societé de Biologie, with regard to the pressure which an experiment of the pressure which as the produced by electrolyting perform on gas in a closed space. Which the highest principal performance and in this way of the state of the third performance of the state of the performance of the state of the performance of the per

THE first series of lectures given by the Sunday Lecture Society begins on Sunday afternoon, October 18, in St. George's Hall, Langham Pikee, at 4 p m,, when Sir James Crichton Browne, F R S, will lecture on "Brain Rust." Lectures will subsequently be given by Mr. Frank Kerniake, Mr. Wilter L. Bicknell, Mr. W. E. Church, Prof. H. Marshall Ward, F R S, Mr. A W. Clayden, and Sir Robott Ball, F R S.

An important paper upon persulphates is contributed by Dr. Marshall, of Edinburgh, to the October number of the Journal of the Chemical Society. The aphydride of persulphunc acid. SaO2, was obtained by Berthelot in the year 1878, by subjecting a well-cooled mixture of sulphur dioxide and oxygen to the silent electrical discharge. He afterwards found that a substance possessing oxidizing properties, and which appeared to be persulphuric acid, was formed in solution during the electrolysis of fairly strong solutions of sulphurie and; it appeared, in fact, to be identical with the substance obtained by dissolving his crystals of S2O, in water. The anhydride does not dissolve in water without partial decomposition, a considerable proportion decomposing into sulphuric seid and oxygen, and hitherto no salts of persulphuric acid have been obtained in the solid state. Dr. Marshall has now succeeded in obtaining the potassium, ammonium, and barrum salts in fine large crystals. During the course of an experiment in which an acid solution of potassium and cobalt sulphates was being electrolysed in a divided cell, it was found that a quantity of small colourless crystals separated. A solution of these crystals in water gave only a faint precipitate with barium chloride, but on warming barium sulphate slowly separated and chlorine was evolved. The solution also liberated iodine from potassium lodide. The crystals were, in fact, potasslum persulphate, KSO4. It was next sought to prepare them

from hydrogen potassium sulphate. A saturated solution of this salt was submitted to electrolysis in a similar apparatus, and at the end of two days a white crystalline deposit of potassium persulphate commenced to form. The crystals were from time to time removed until a considerable quantity of them had been accumulated. These, when recrystallized from hot water, yielded large tabular crystals, and sometimes long prisms when formed at the surface of the liquid. Analyses of pure samples yielded numbers agreeing perfectly with the formula KSO. From determinations of the conductivity of dilute solutions it would appear that the correct molecular formula is KSO, and not K.S.O.s On ignition of the salt, oxygen and sulphuric anhydride are evolved and potassium sulphate is left. The crystals are not very soluble in water, 100 parts of water at 0° dissolving 1 77 part of K5O. The aqueous solution gradually decomposes, hydrogen potassium sulphate being formed and oxygen liberated The pure freshly prepared solution is neutral to test paper The solution yields no precipitate with any other selt by double decomposition, the persulphates of most other metals appearing to be more soluble than notassium persulphate. A solution of lead hydrate in potash yields a precipitate of lead peroxide on boiling With silver nitrate no immediate precipitate is formed, but the liquid gradually acquires an inky appearance and after some time a black precipitate of silver peroxide, AgO, is deposited It would appear that silver persulphate is dissolved by water Fehling's solution gives a red precipitate of copper peroxide Ferrous sulphate is rapidly oxidized to ferric with considerable rise of temperature. Organic colouring matters, such as litmus, are bleached. Alcohol is oxidized to aldehyde in presence of water, but absolute alcohol has no action on solid potassium persulphate The pure crystals have a cooling saliae taste, which leaves a peculiar after-taste. The impure salt cyclyes ozone slowly Freshly prepared crystals have no odour, but after a time they emit a peculiar pungent odour quite different from that of ozone, and which appears to be due to persulphune anhydride When warmed with concentrated nitric or sulphuric acids the oxygen is liberated largely in the form of ozone. With hydrochloric acid chlorine is evolved. The ammonium salt NH4SO4 has been prepared in a similar manner, it crystallizes in long prisms and much resembles the potassium sait The barium sait crystallizes in beautiful large interlocking prisms containing four molecules of water of crystalli-

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (Macacus cynomolgus 5) from India, presented by Mr J Barratt Lennard; a Rhesus. Monkey (Macacus rhesus 9) from India, presented by Miss Corrie Chisholm : two Common Marmosets (Hapale jacchus) from South east Brazil, presented by Mrs Frederick Betts, two Bernicle Geese (Bernicla leucopsis), two Brent Geese (Bernsela brenta), European, pretented by Mr Cecil Smith, a Gamet (Sula bassana), British, presented by Dr. Davis eleven Gold Pheasants (Thaumalea pula 81), two Amherst Pheasants (Thaumales amherstie & &), two Silver Pheasants (Euplocamus nycthemerus & 9) from China, a Common Pheasant (Phasianus colchius &), British, four Ruddy Sheldrakes (Tadorna casarca), European, presented by Mr. Edwin J. Poyser; a Common Chameleon (Chamaleon vulgaris) from North Africa, presented by Mr. F. Manners; a Macaque Monkey (Macacus cynomolous) from India, deposited.

OUR ASTRONOMICAL COLUMN.

MEASUREMENTS OF LUNAR RADIANT HEAT.—Numerous measurements of linear radiant heat have been made at Bur Castle Observatory by Lord Roses and Dr. Copeland, and the results obtained have been published from time to time. During the total lunar eclipse of Cutober 4, 1884, Dr. Otto Bondaicker,

Lord Ro se's present assistant, carried out a senes of observations for the purpose of testing the artiking result previously arrived at by Dr. Copeland, viz., that "the maximum of heat exceed to occur some that before fail moon." If we then nearly proportionally to the light, becoming inappreciable on reaching the limits of totality. The minimum of heat apparently fell later than that of illumination. But the most remarkable fill later than that of illumination. But the most remarkable contact with the penumbra, and the commencement of total phase, all appreciable radiation vanished, between the end of total phase and the last contact with the penumbra, and even forty municia later, the heat had not returned to the vanished facts are remarked upon by Lord Rose in an introduction to a paper by Dr. Boeddicker, guing the results obtained during the maximum contact with the penumbra, and a decrease of heat seems even then to have set in. But excluding this distinct of the contact with the penumbra, and a decrease of heat seems even then to have set in. But excluding this disministration of heat exhibited by the curve connecting the discretization of the set and the contact with the penumbra, and a decrease of heat seems even then to have set in. But excluding this disministration of heat exhibited by the curve connecting the discretization of the set and the set of t

Two New Variable Stars—The Rev T E Espin has found two new variable stars in Cygnus, viz D N + 36 3852 and 1 M + 49 3339. They are both of a strong red colour The first has a Type III. (Group II) spectrum, and the second belongs to Type IV (Group VI)

A NEW ASTRACIO,—The asteroid observed by Dr Palus on August 22 turns out to be Mediusa (12), as was suggested by Dr Berberich. On this account, the asteroids from (11) to (12) must be numbered from (11) to (11), and the one discovered on September 24 by Charlois will be (11)

A NFW COMET —A high comet was discovered on October 2, by Mr. E E Barnard, at Lick Observatory, in R.A 7h 31m 24s, and Deel -27° 54′ It was moving to the south east

THE IRON AND STEEL INSTITUTI

THE autumn meeting of the Iron and Steel Institute was held on Toesday the 6th inst and Weinberday He 7th insti, under the presidency of Sur Frederick Abel. After the excellent of last year's meeting in the Unsted States, the gathering meeting in the Unsted States, the pathering the continuous of this Sciercy to had done not need to see the the custom of this Sciercy to had done, and the second, in the autumn, either in the provinces or abroad. This year at was proposed that Birung's being int London, and the second, in the autumn, either in the provinces or abroad. This year at was the great town of the Mildands does not appear to have re-forthcoming, the Council was thrown back on the meeting, but the great town of the Mildands does not appear to have re-forthcoming, the Council was thrown back on the meeting-bit in one point, at any rate, the meeting was a success, as on Tuest-day a larger number of member travelled down to Woolwich, where a waith had been arranged to the Royal Areasal, than the council was the scale of the Council was thrown as the Council was thrown the scale of the Council was thrown as the council was the scale of Council was thrown as the scale of Council was thrown as we consider the scale of Council was thrown as we considered the scale of Council was thrown as we considered the scale of Council was thrown as a scale of the Council was thrown as the scale of Council was thrown as the scale of Council was thrown as a scale of the Council was thrown as the scale of Council was thrown as the scale of Council was thrown as the council was the scale of Council was thrown as the scale of Council was thrown as the council was the scale of Council was thrown as the scale of Council was thrown as the council was the scale of Council was thrown as the council was the scale of Council was thrown as the council was thrown as the council was the council wa

where a visit had been arranged to the Koyal Arsenas, tans perhaps have even being pot together before on an eccurson, The executions are generally the leading feature of the meeting just past—namely, that to Woolwuch Arsenal. The following is a list of the papers read—On the constitution of ordance factors, by Dr William Anderson, F. K.S. Director-General of Ordanner Fastorses; on the measuring untrusential Woolwich, by Captain Holden, R.A., Proof Officer at Woolwich, tog the manifacture of continuous sheets of malleable aroa and steel direct from fluid metal, by Sr Henry Bessmer, F.R.S., on illustrations of progress in material for shiphulding and engineering in the Royal Navil Exhibition, by W. II White, C.B., Chief Consurator, on the forging press, by W. White, C.B., Chief Consurator, on the forging press, by W. Lausen of and a field, by F. J. R. Carulla, Debris, on the climits of the control of shiphur from page-no by J. Massacer, of Hearth, of the Control of Section of Sectio

Sortool, by B 11 Inwaite, Laverpool.

Woolwich, D 74 Anderson's contribution was taken first. It is a currous fact that the Director-General of Ordnance Factores, whose admires nead to claim, before he occupied his present whose admires nead to claim, before he occupied his present man, should have contributed what is perhaps the least scentific paper to be found within the Transactions of the Institute. The paper was what its tule indicated, strictly a description of the paper to be found within the Transactions of the Institute. The paper was what its tule indicated, strictly a description of the comprise the Laboratory, Gun Factory, and Carrage Department at Woolwich, the Gunpowder Factory at Waltham Abbey, and the Small Arms Factores at Panied Lock and Birmighton worked on commercial principles. Dr Audieron is an accurate work in the field of mechanical engineering which he has done, factoring establishment were worked with a view to profit after the manner of Woolwich Arienal, the profits probably would be very small. The paper tells us that \$4,00,000 is invested in 17,000, of which 17,000 are at Woolwich in the finding the following paper in the interest of \$1,130,043, and metansis for \$1,130,043, and metansi

Capian Holden's paper was on an interesting subject, but was far too bref to treat it an aptiving approaching an adequate was far too bref to treat it in aptiving approaching an adequate on the control of the control

all sources of error in the instrument, and the precasions taken are briefly outlined in the page, and the precasions taken. After the reading of these two papers the members were conducted round the Arsenal, but such official wrath was threatened against any person who wrote for printing about anything he part of the proceedings.

saw that we are too ingineers on make uning exercises to map of the proceedings, the metting the members assembled at the institution of Civil Engineers, für Frederick Abet, the Presentent, sayan occupying the chile. The first paper taken was a contribution by Sur Henry Bessenser, in which he described an invertion of his, devised easily Jall'a contury ago. This consistency is the contribution of the co

plicated and costly methods should have stood so long, consider-ing that Sir Henry Bessemer's patents have long since expired, ing that Sir Henry Desember's patents have long since expired, and his direct proces is no pen to anyone to adopt. The metal, and the direct proces is not pen to anyone to adopt. The metal, to be afterwards rolled into alabs or billets, its just poured on to the top of a pair of water-cooled rolls placed with their axis, in the same horizontal pinne. The rolls are caused to revolve, and the molite metal finds it, way down between the space left. and the molten metal finds its way down between the space left between them, and is thus rolled out into a continuous plate or between them, and is thus rolled out into a continuous plate or sufficient to solidly the metal. That the process is provide Sir Henry proved over droty years ago, that it may be made commercially successful appeared to be the unanimous opinion of the many competent critics who spoke in the discussion of the many competent critics who spoke in the discussion Under these circumstances it would seem that the only reason why there should not be a radical change in the way of why there should not be a radical change in the way of manufacturing steel plates is that the process is open to every one, and, as there are no patent rights to be acquired, it may be worth no one's while to go to the initial expenses of starting a new process just to show competitors how to do the same

Mr. W II White's paper on the shipbuilding material at the Naval Exhibition was a useful and interesting contribution, although not so exhaustive as might have been desired. It would, however, he too much to expect so important a public would, however, let too much to expect so important a public servant as the Director of Naval (onstruction to devote his time to writing testisties for technical Societies. What Mr of shipbuilding has been simplified and cheepened by the steel manufacturer, who now rolls many special sections, such as 2 bars, thannot bas, If Lawr, T bulbs, and angle bills, thuy saving a vast amount of building up and riveting in the actual saving a vact smount of buttoning up and reveiling in the actual construction of the ship. The increase in the size of plates, both for ship and boiler work, was also pointed out by the author. Two specimens of buter plate are shown in the Exhibition, which are both 11 in thick and respectively 42 ft. Examination, which are not it is in the non-tespectively 42 it tools by 65 ft wide. An other way in which the steelmaker and founder has helped the shiplistiller is in producing complete parts of ships, such as stern frames and stems, especially the spir sems of war vessels, which necessarily have to be of measure construction. In old days, when such parts were under of wrough iron, the forging had to he machined to form the recesses or "rabbets" necessary far and in the case of such heavy articles was most difficult to excessively contained to the machined to form the recesses or "rabbets" necessary far and in the case of such heavy articles was most difficult to excessively contained to the case of such heavy articles was most difficult to and in the case of such neary articles was most cimeus, co-accomplish at all. With steel casting a little or no machining is required. Mr White exhibited a large hull diagram of a ram bow for a recent battle-ship. The part issimade hollow, or rather recessed, and shelves are cast on to receive the plating of the decks: and the sitachment of hreats thook, & The shanglor raiher recessed, and shelves are cast on to receive the plating of the decks, and the attachment of breast hooks, &c The author also referred to the exhibits of armour plate made at the Exhibition, but the subject is to lengthy for us to go into here, excepting to say that nickel steel has been proved by test to show such good results for amour that some of the "econdary armour plating for five first class battle-ships is now being made of that material.

of that material.

Mr. W D Allen, in his paper, described a forging press, which, although it has been at work for some years at the Bessemer Works in Sheffield, is so ingenious, and so new to which, although it has been at work for some years at the lessement Works in Schleids, so in egenous, and so new to be element to the some some some some some some some has the appearance of a steam liammer, and, indeed, there is a steam cylinder at the top, just as an a hammer. The use of the steam, however, is only to raise the tup when the hydraulic programs are released. The press consist of an anvil block below pressure as released. The press consist of an anvil block below ram works in a hydraulic cylinder, and is scarred through the top end of the latter in the shape of a stout staff or shank, which may be described as a tail rod to the ram. Attached to this is the pittor not off the steam prior, the latter of comes working in its own cylinder. The steam cylinder and hydraulic cylinder, the hydraulic cylinder, the pulped with water at pressure by a sattable pump, the barrel of the pump being in direct communa cadm with the bydraulic cylinder, there being no valve of any kind between the two. If we have made our explanation clear, stroke with the pump plunger (the same water flowing back-wards and forwards continuously), at being remembered that the There are actually two plungers, the pump being of the displex type.

* There are actually two plungers, the pump being of the duplex type but this is a detail which does not affect the principle

NO. 1146, VOL. 44]

steam cylinder has always a tendency to lift the ram. Thus, upon the pump making a forward stoke, the water in its barrel is forced into the hydraulic cylinder; the ram is thus forced is forced into the nyiriatuic cylinder; the ram is this forced down, and gives the necessary queeze to the work on the anvil. The pump plunger then starts on its return stroke, and so, by enlarging the space in the pump harrel, enables the hydraulic man to rise and press the water out of the cylinder and back into the pump. The rising of the ram is caused by the lifting auton of the team micro and the pump and the pushon. The latter, it will be remembered, heing sitached to the ram. Of course the water remembered, neing attached to the state of this pressure on the downward stroke. The chief use of this press is to produce downward stroke The chief use of this press is to produce work of any given thich-nescs within the range of the machine. This rend is attained by regulating the volume of water used The action may be explained as follows: We will suppose, merely for simplicity sake, the content of the pump barrel to be one cubic foot, and that of the hydraulic cylinder, when the ram is at the full extent of its stroke, to be two cubic feet. We will neglect the connecting sipe between the two, as that is not a variable and does not affect the principle. If there be admitted to the pump but one cubic foot of water as the plunger into the hydraulic cylinder, and the ram would therefore only descend one half its stroke If the stroke were two feet the travel would be 12 inches, whilst there would be 12 inches travel would be 12 inches, whilst there would be 12 inches, of space between the anvil and the lower side of the squeezing tool on the end of the ram. Objects of 12 inches, or above 12 inches in thickness, could therefore be forged. If, however, an article 6 inches thick had to he worked, another half cubic foot of water would have to be admitted the pump barrel would only accommodate one cubic foot of water, the extra half cubic foot would remain permanently in the hydraulic cylinder, and the ram would therefore not go, by six inches, to the top of its stroke, in other words, the traverse of the ram would be carried six inches nearer the anvil. It will be remembered that the upward movement of the ram is effected by the seems cylinder, which is powerful enough to lift the dead workpit of the inn, but is overcome by the hydraulic pressure It will be seen that by regulating the wolams of water in the lift of lift by the steam cylinder, which is powerful enough to lift the dead warn me chance or getting a little too much work on at the last minutle, cannot equal the alsolutely ourrect results of this automatic system. There is a very ingenious valve for regulating the admission of water to fine gradations, so as to get work accantacly to gauge, but we have, perhaps, given enough description of mechanism for one article.

Mr. Carulla's paper was interesting and suggestive. He was reasoned in multium baseomers.

engaged in melting Bessemer scrap in pots when a crucible gave way in the furnace just as fusion was nearly complete, the greater part of the contents flowing out into the fire. The greater part of the coolents flowing out into the fire The meller was up withinging the crucible out, and, instead of finding an empty broken crucible in the tongs, he discovered a number of shell corresponding us hape with the please originally charged, obtained to the property of the control of the please originally charged, phenomenon, upon which he invited an explanation. That discovered in the please of the control of the please of the control of the control of the peakers, but of the way in which the business of these meetings in carried on The remain applies not only to the foundation of the control of the total control of the control of the control of control of the control of the control of the control of control of the Iron and Steel Institute, but to most of the technical Societies of the same class. When a meeting in held, a mad of papers are grought forward and read more or less hurrheidy, and the paper of the moment. It is seedless to point out that no austastory discussion of matters involving scientific principles can be carried on in this way. Mr. Carulla's paper is, as we have aid, suggestive, and a complete explanation of the facts be tattes would doubless lead to most important discoveries in

The prevs ram makes a stroke of si inches, and its diameter is 30 inches. The total pressure at 3 tons per square inch would be 1700 tons.

metallurgical science. In such cases as this we think it would metalizingual science. In such cases as this we think it would be wise to read the paper and then postpone discussion small the next meeting, or, by preference, to have the paper printed in appearance call for discussion. If would appear evident that the interior of the precess of scrap had a lower meltung point than the externer part which formed the shells obtained, and the explanation of the variation is melting-point was the point requiring consideration. Liquitors of the elements is raturally explanation of the variation in melting-point was the point requiring consideration. Liquid con of the elements is raturally required to the control of the control is raturally included to the control of the control of the control of the liquition as itself an obscure matter. Mr. Sheisu would explan tender the increase pasts more easily feasible. It is had, in raking tender the increase pasts more easily feasible. It is had, in raking the control of the control of the control of the control of the same metal, the case this formed being filled with graphitic carbon. Mr Galbrath attributed the phienomenon to the surface of the metal poses having absorbed an inclusible outderwess at a high temperature There was, however, more in the circumstanges

temperature There was, however, more in the circumstances described than the meeting was prepared to explain of hand, and it would be well if the discussion could be reopened at the pring meeting on brought in again by another pages, proposed the most valuable of the meeting. It is a pleasing thing to see a foreign steelmaker patting his experience so unereverdly at the disposal of his English fellow-workers, and the thanks of the lastitute are doubly due to the author for his valuable and practical paper. There is also an economic lesson in this metter, for the apparatus described owed his surfacetion to the matter, for the apparatus described owed its introduction to the German collier; great strike of two years ago. Since then these has not only been a dimension in the amount of coal wrought, but the quality has also fallen only. So that the proportion of deat-planitation process, the method of which forms the subject of the paper. Manganiferous molten pig. poor in sulphur, is added to sulphuretted pig roon, poor in manganese; the result being that the method is described by the properties of the paper. Manganiferous molten pig. poor in sulphur, is added to sulphuretted pig roon, poor in manganese; the result being that the main is described pinch pinch forms and allow a sulphure and the pinch p of about twice the size would be advisable. Details of the working are given by the author, and will be of great use to steelankers working with phosphore pig. In the discussion the inventor, so I've the leaf the limitating that a waring of 22.47, per ton could be made by this method over the process of re-miding pig in the cupols; is step which has to be ladeen of re-miding pig in the cupols; is step which has to be ladeen farmace. In the large mixer, metal from two or more firmaces on the brought tengenter, we was contribution by Mr. B. The cupy remaining replaces as a contribution by Mr. B. The cupy is the state of the state of the metallungued department of the Sheffeld Technol School, which was read in burf abstract by one of the clerical staff, after which the meeting was tomposity to a condition by the usual vote of thanks.

CARL WILHELM VON NAGELI.

THE death of Carl Whileim von Nageh, on May 10, 1891, removes the last surrivor of that distinguished group of betanitz who, side by side with toologists such as Schwann and history of the career of Nigeh; as of popular there more than the career of Nigeh; as of popular there is no standard to the career of Nigeh; as of popular the held a sleding position in the advance of the scene; rad, while has leading position in the advance of the scene; and, while has most recent work it is touch with those letter developments of bology which are connected with the name of Weismann. His work reached every side of the science. Systemate bology, the contract of the science of the scie THE death of Carl Wilhelm von Nageli, on May 10, 1891,

was devoted to coors, but he soon showed a taste for naturas history, which appears to have been in some degree inspired by his sister. His education as a boy was begun at a private school, of which his father was one of the founders, and was completed at the Zurich Gymnasium, where he did well. He

then matriculated at the recently-established University of then matriculated at the recently-established University of Zurich, with the view of studying medicine. As a student, he is said to have been strongly influenced by the "Naturphilosophie," as taught by Oken. He soon lost his taste for medical studies, and, owing to his mother's influence, was

medical studies, and, owing to his mother's influence, was allowed to migrate to Genera, where he devoted himself to the study of hotany under De Candolle. Nageli took his doctor's degree at Zuinch in 1840: his dis-sertation on the Swiss species of Circitism was decidiated to Oswald Heer, and was his first contribution to that minute investigation of species which formed so characteristic a part of his life work.

his life's work. Subsequently Nageli spent a short time at Berlin, studying, among other things, the philosophy of Higgel. A metaphysical spent of the property of the studying among other things, the philosophy of Higgel. A metaphysical few studying the studying th influence of Schleiden however, is manifest throughout, someintuence of Schleiden however, is manifest throughout, some-tmest in an injurious degree, though the independence of Nageli times and the state of the state of the state of the state of the policy of the state and on his wedding tour he spent a long time on the south-coast of England, and there collected much material for his important work on "Die neuern Algen-systeme," published in

coast of England, and there collected much maternal for his imponents work on "Die neueren Algen systems," published in Stock and the state of the continent he became a Privateleust at Carona had lecture at the veternary school, and ason afterwards he was appointed Professor Estraordinstrus. such as few awants can have enjoyed. Without attempting to give an adequate account of Nigeli's scientific work, a task which would far exceed both the limits of this article and the powers of the witter, some idea may be given of the salient points in his career as an investigator. Nageli's far histological paper, so far as we are aware, is on the development of pollen (1841). This already marks a de-

The details of Nigeli's life are taken from the funeral address delivered by the colleague, Prof. Cramer, and published in the News Zarcher Zeitung for May 16, 1801.

ided advance on Schleiden's theory of free-cell formation, for odded advance on Schleiden's theory of free-cell formation, for Nageli maintains that the spoon innother-cells are not formal dreetly around a cytoblast (nucleus) but around the whole granular contents, in the modile of which a fee cytoblast lies from the influence of Schleiden's histological liteories. It is interesting that in this paper he desembed and 1 clearly figured the two nucles in the pollen-grain of an CEnothers, though he did not know that this was a contact phenomenon. The jimportance of this observation was not appreciated until Elfving, Strasburger, and Guignard, investigated the subject in our

Nageli's "Botanische Beitrage" contributed to the volume of Lisance for 1842, include some important papers. In those on the development of stomata and on cell-formation in the root-apex, he endeavoured to reconcile his own accurate observations apex, he endeavoured to reconcile his own accurate observations with Schiedenian theories, and was thus led to oppose Unger, who had already recognized that vegetative cell-formation is a process of division. A paper on Fungs in the interior of cells is interesting, because the existence of such endophytic forms was at that time regarded as establishing a presumption in about of a school and the processing the superior of the processing that the control of the processing the proces

apontaneous generation
The Zestschrift fur Wissenschaftliche Botanik, 1844-46, is a very remarkable publication. It never got beyond its first volume, but it may be doubted whether any book of its size has been more important for the progress of the science. Nageli's introductory paper, "Ueber die gegenwartige Aufgabe der Naturgeschichte, insbesondere der Botanik," is very metaphysical in tone, and is not free from a certain youthfal pedantry Great stress is laid on the absolute difference of species—a con-ception which, as Nageli tells us in one of his later works, did ception which, as Nagelt tells us in one of his later works, did not prevent his believing eren then in the origin of species by descent. The study of development is treated as a philosophic of the second of the

crystalization Some of the most doubtful of his own later generalization, however, were affected by the same source of error-manely, too great eagerness to find a simple physical explanation for biological phenomena. Nageli, in this paper, devotes much space to the distinctions between annuals and plants. He decirvely repers the idea of between the same and plants are the decirvely repers the idea of world for the property of the same property of

would contrainct in a "Disoutnest der Begrine"—an argument which now seems strangely out of place in natural science the whole paper is of great interest as showing the print of view from which biological questions were regarded at that time by a brilhant and philosophical naturalist just entering on his life; work

the more correct, still Nagel established the main facts of the

division of the nucleus and of the cell on a broad basis of division of the nucleus and of the cell on a broad basis of observation. These papers, as well as one on the intricular structures in the contents of cells (nucles, nucleoil, chlorophyll granules, &c) were translated by Henfrey for the Ray Society, to the great benefit of English students, as the writer

Society, to the great onemat or anguins students, as the written of this article can testify.

In the same journal there are several algological papers, the most important of which is the complete and admirable account of Casterga proisitors, the extraordinary histological stricture of which as the relationship to the other Siphones Nagel already thoroughly understood. It is interesting that in this paper he describes both the cell-wales need as growing by apposition, a view to which we have now returned, owing to the

observations of Strasburger and Noll, in opposition to Nageli', own later theory of intussusception propounded in 1858

The paper on Delesseria hypoglossium contains an elaborate account of the cell-divisions by which the thallas is built up Nageli here characteristically attributes great importance to the introduction of ideas of absolute mathematical form into

introduction of ideas of absolute mathematical form into physiology and systematic botany. The discovery of spermatozoids in the Ferni is one of the most important recorded in this volume. The essential points in the structure and development of the antheridia are described. in the structure and development of the antheridia are described rightly, and the movements of the spermatozards very accurately traced. Nageli calls attention to the nuclear reactions of the substance of the spermatozoids. He demonstrates the homology of these bydies with those of the masses and Chara and of Nazeli was at that time necessarily completely in the dark as to the relation of the spermatozoids to spore formation.

dark as to the relation of the spermatozonis to spore formation, for the archegionia and the process of fertilation were first dis-covered by 8 immski four years later Among other papers of final immstal importance may be mentioned that on the growth of missee, in which the apical cell-divisions and the development of the protonems are clearly a work which laid the foundation of our knowledge of the distribution of vascular bundles, and that on the reproduction of the Rhizzerps. This last is especially interesting. It is the Rhizocarps. This last is especially interesting. It is directed though very cautiously, a rainst the Schleidenian theory of fertilization as applied to these plants It is singular hov this theory, according to which the end of the pollen tube, after penetrating the embryo sac, itself became the embryo, took possession of the minds of botanists at that time, and led some possession of the mains of locianist at that time, and test some times to the strangest confusions, sometimes to a chance recognition of homologies, which could only belegitim telly proved at a later period of research. In the case of the Rhinocarps, the shell tenan theory assumed that these plants were really Phanerogams. Hence we find that he and Nazel agree in Prancogams there we not that he and Nagel agree to aching their microspores pilengrann, their microsporangit anthers, their microspores embryo-sact, and their macrosporangia ovules, a terminology which very nearly expresses our present view of their hom logics as established by Hofmeitter Nagel discovered the spermatozoids of these plants as well as

sugeri ossovered the spermanucolos of traces pairs as well as the probabilism and archegorian, but he shows the greatest reserve in correcting Schilden's extraordinary mittakes. It is worth remarking that at this early period the homology of pollen-grains with spores was generally admitted, and in first we wonder how this true result could have been arrived at hist we wooder how this true result could have been arrived at so prematurely. Here again the Schledenian theory affords the explanation. The pollen grain was regarded at a spore, which on germination produced the embryo-plant, not as do the spore of Cryptogams in the open sir, but within the embryo sac of the route. This conclusion was of course strengthene! by a mor-legium the argument drawn from a comparison of the mode of

legitimate argument drawn from a comparison of the more or origin of polling grains and spores.

A less fortunate result of the theory asperas in a poper.

A less fortunate result of the theory asperas in a poper.

Blatter "Nagel here erroneously attribute to the stem and its branches an endogenous origin. That this holds good for the primary aris, he proves by stating that it is derived from the polling praise, which itself arises endogenously within the ambier? also results in the state of bottomical operations during the sorbite salts results into the state of bottomical operations during the carlier

on account of their superficial resemblance to the spore-tetrads of the higher Cryptogams The carpospores, which are the real sexual products, he regarded as gemme like those of Marchantsa, with the cups of which he compared the cystocarps Sich views were excusable at that time, but Nageli, as we shall see, adhered to them later on with excessive pertinacity.

Nageli was perfectly acquainted with the conjugation of

Desmids and Zygnemaceæ and imperfectly with the fertilization of Vaucheria, but he imagined that these processes were too in

or vaucnerss, out ne imagined that these processes were too in-constant to be regarded as sexual.

Nageli was at that time much more successful in dealing with the regetative organs of the Algze, and he rightly protested against the generalization current down to out own day, that

all Algae are destitute of leaves

His conviction that the Alge are without exception sexless led him in 1849 to reject Decuisne and Thuret's discovery of the spermatozoids of Fucus, which he regarded as spores. Of his spermatozoda of Iwoin, which he regarded as spores Of his inter algological papers, the most important is that on the Ceraniacese, published in 1601. In this the procupas and crinckgrages, the rest femals organ, are described and accurately still maintained his old view of the sexuality of the tetraports. The whole credit of the discovery of the real variet of the tear that the contract of the contract of the contract of the The "Pflanerapproplogogethe Unterschungen" of Nagel and

Cramer (1855-8) contain among other papers of importance Nageli's luge work on starch grains (about 600 quarto pages '), which is of great general value as embodying his views on the growth of starch and cell-wall by intussusception and on the molecular structure of organized bodies. For many years this molecular structure of organized bodies. For many years this micellar theory, as it was afferwards called, was regarded as Nageli's greatest achievement. Sachy, in 1875, said in his "Ilistory of Botany". "Nageli's molecular theory is the first successful attempt to apply mechanico physical considerations to the explanation of the phenomena of organic life." More recent i-esearch has shown that this attempt, life its predecessors, was premature, and though. Nageli's ingenous and carefully elaborated hypotheses must still arouse our admiration, we can scarcely now regard them as having added must lo our knowledge either of the growth or structure of organized bodies. The book on "Starch Grain," however, quite apart from theoretical considerations, will always remain a mixvellous and discriptive matter in addition to the specializations which have made it famous. The micellar theory was further devoted in sub-equient papers "on the behaviour of polarized light towards vegetable organisms" (1862), all "on crystalloid proton bothes" (1862), and "on the internal varieties of professed form in the important work on the intero-cope, published by Nagel and Schwenderer in 1877. elaborated hypotheses must still arouse our admiration, we can

perfected form in the important work on the micro-cope, pub-ished by Nageli and Schwendener in 1877. The papers in the "Physiologische Untersuchungen" bear the name of Nigeli or of Cramer respectively, but it appears that they mutually assisted each other throughout, hence it is not out of place to mention here Cramer's fine researches on the apical growth of Equiscium, which to this day serve as a model (rarely approached) for all such investigations

No sooner were these investigations with Cramer completed than another great undertaking was commenced in the publica tion of the "Beitrage zur Wissenschaftlichen Botanik" (1858-68) This began with the great paper "On the Growth of Stem and Root in Vascular Plants and on the Arrangement of the Vascular Bundles." This is the most important of Namel. This is the most important of Nigeli's purely ananot too much to say that the bulk of our knowledge of the disnot too much to say that the bulk of our knowledge of the dis-tribution of vascular tissues in plants still depends on this work. Other valuable papers in the "Bettrage" are those on the use of the polarizing meroscope, on the growth in thickness of the Sapindacee (another ideal pattern of anatomical research), and on the origin and growth of roots, in which stil i tgtgelo-coperated. Until the quite recent work of Van Tieghem and Doultot, this was undoubtedly the most important investigations. on the subject.

Among Nageli's later works there are two which have had a

lasting influence on our views as to the biology and physiology of the simplest plants. In "Die niederen Pilze" (1877) he treats of moulds, yeasts, and bacteria in relation to infectious diseases and hygiene. In this work an excessive scepticism is displayed as to the existence of definite species among the lowest organisms, such as bacteria. There is no longer any

doubt that species are neither more nor less distinct a these simple beings than among the higher plants, but Nageli did a real service in showing that each of these species may appear in a number of morphologically and physiologically

appear in a number of morpuosage...,

"" in flancate."

It remains to consider briefly an aspect of Nageh's work, which is from some points of view the most interesting of allnamely, his relation to the theory of descent. The elaborate observations on variable species, especially in the genus Hiera-crum, which Nageli carried on throughout his whole life, side by

coun, which Nageli carmed on throughout his whole life, side by side with his thirotogical and physiological work, specially qualified him to take up an independent position with reference to the problems of evolution. In his paper, "The Rastate for the frequency of the contrastion of the light of Darwin's work. It has belief, however, in the origin of species work. It is also the forest of the contrastion of the contrastion of the contrasting of to accept it as antorsing a sufficient explanation of evolution. He believed that variation has a definite direction, always tending towards the greater complexity and perfection of the organism (Vervollkommungstheoric). On this view the development of the race, like that of the individual, has a definite course as signed to it beforehand. He protests that there is nothing supernatural involved in this doctrine, and that it does not He protests that there is nothing

supernatural involved in the decrine, and that it does not moce-waitly require soldien transformations. On this latter question, however, he species very uncertainty, and states that question, however, he species very uncertainty, and states that question, however, he species very uncertainty, and states that the state of the species of the species

But, whatever view may be taken of this speculation, it must be admitted that Nageli saw clearly the great fact—since brought be admitted that Nageli saw clearly the great fact—since brought home to us by the works of Westmann and his school—that the causes of variability are internal to the organism. This important doctrine, based on original experiments and observations, is maintained in a paper entitled "Ueber den Emflussusverer Verhaltnisse and die Varietatenbildung im Pflanzeir-reiche" (1863). He shows that "the formation of the more or less constant varieties or races is not the consequence and the iess constant varieties or races is not the consequence and the expression of external agencies, but is determined by internal causes?, while the modifications directly produced by external influences are inconstant, and do not give rise to varieties. We think it must be allowed that, on this essential point, Nageli was at that time somewhat in advance of Darwin himself. Other works of that period deal with the laws affecting the

distribution of species, and with the phenomena of hybridiza-tion. In the "Theore der Bastardbildung" (1866) the peculiarities of hybrids are explained as due to the favourable or unfavourable changes produced by crossing, in the internal coadaptation of the organs of the offspring.

A paper on the social origin of new species (1872) results in the conclusion that groups of new forms are likely to asise simultaneously, rather than isolated new species.

Finally, something must be said of the great work published in 1884, "Die mechanisch-physiologische Theorie der Abstam-mungslehre," which states at great length Nageh's final con-

c'usions as to evolution and heredity The fundamental idea of this weighty work is the conception of the Idioplasm, namely, of a definite portion of the general protoplasm, to which alone is This idea, committed the transmission of hereditary characters committed the transmission of hereditary characters. This idea, as Weimman points out, is a fruitful one, and will hive, and is indeed incorporated in all recent theories of heredity. Nagelis peculations, however, as to the details of the distribution and molecular structure of this thoplasm are of much more doubtful value, and rest on no firm basis of actual observation.

Nageli rightly argues that the character of the fertilized egg must be determined by a minute amount of idioplasm and must ue determined by a minute amount of idiophasm and not by the cytophasm generally, because the characters of the male and female parent are on the average equally represented in the offspring in spin of the enormous difference in the bulk of the cytophasm of operantozoid and ovum

It was only, however, after the idioplasm had been identified by Weismann and Strasburger with a detinite constituent of the

by Weismann and Strasburger with a definite constituent of the nucleus that the theory acquired a positive basis, Nagel in the "Abatammunglehre" points out that fertil ration can only consist in the direct union of solid displaymic bodies, and this on theoretical grounds arrives at a conclusion which has been fully confirmed by the observations of Van Benc-den. Strasburger, and Guignard He also shows that while in the higher organisms idioplasin alone is necessarily transmitted from parents to off-pring, in the increase of the lower plants and animals by division, the descendants acquire a share of the nutritive protoplasm also. Hence in the latter the conditions of tive protoplasm also Ilence in the latter the conditions of cultiue may directly iffect the descendants, as Nogeli found in the observations on bacteria. The conditions of the continuity of the continuity of the condition of the continuity of the germ plasm, as brought forward a year later, though on other points there is a wide divergence of opinion Nageli massis in his preface to this book, that the subject

of heredity can only be authoritatively treated by a physiologist, and he no doubt regarded his micellar theories as an important contribution to the question. In this his view is some what one sided, and as a matter of fact all recent advance in our knowledge of the essential points in reproduction has

come from the morphological side.

come from the morphological side.

Nageh's attitude towards the question of spontaneous general Nageh's attitude towards the question had no donice as control of the spontaneous origin of many bungs, and thought that the could be experimentally demonstrated. In 1865, he gave up the experimental evidence, but believed in the origin de news at all poochs of simple vegetable cells. In the "Datamaning when" he still maintains that spontaneous generation is constantly in progress, but no longer holds that even the lowest known organisms can arise in this way. His supposed primitive living things (Problem) are as much more simple than bacteria, as these are more simple than the highest animals or plants

As regards he causes of evolution, Nageli in his great work opens to limit the field of natural selection even more narrowly than in his earlier e-says. Its function, according to his later views, consists in the separation and definition of races by later views, consists in the expansion and elemition of races by the elimination of ill adapted forms, rather than in determining the origin of the races themselves. In a brilliant illustration be preture natural selection as pruning the phylogenetic tree, though powerless to cause the putting forth of new branches. He still regards evolution as a necessary progress towards perfection determined by the constitution of the organism itself, and more

especially of its idioplasm.

This view is only needed if we assume with Nageli the existence of purely morphological characters—of characters, that is, which are not, and never have been, of the nature of adaptalions It appears to us to have been sufficiently shown by Prof Welsmann and others that the existence of such characters is an unnecessary assumption As biology advances, we learn every day the function of characters which had before appeared to us to be useless, and the whole tendency of investigation is to prove that all characters what so ever are either of direct use to their present possessors or have been inherited from ancestors, to whom, at the time when they were acquired, they were equally advantageous. It would be difficult to cite a stronger instance of a "morphological character" than the alternation of generaon a "morposogical character" (has the alternation of genera-tions which to clearly characterize the higher cryptogans. Yet it has been lately shown by Prof. Bower that this may well have been an adaptive character at its first origin, the sporophyre being adapted for taking possession of the dry land, while the oophyte, owing to the mode of fertilization, was compelled to retain a lovely and semi-aquatic habit

We have given a very incomplete and imperfect sketch of the life-work of one of the most illustrious of that illustrious band of botanists to whom the chief advances of our science are due of botansist to whom the chief advances of our science are due Much of his work has of necessity been left quite unnoticed But on even a cur-ory glance through the wittings of Nagch the conviction is foreed upon us that he was a man not only of exceptionally wide scientific and philosophical training and of exceptionary wide scientific and philosophical training and of great literary power, but also one of real genus, and as far removed as possible from that narrow specialism which is the breetting vin of so much modern scientific effort. The judgment of Nageli's colleague, I'rof Cramer, that he was "a truly cannot be dismissed as the exaggerated language of great man. great man, cannot be distinsed as the congression important personal affection, but expresses a truth. Though some of his theories may be abandoned, a vast sum of permanent achievement will always remain, and the influence of Nageli on the ment will always remain, and the tombelse age future of our science will be powerful and lasting

UNIVERSITY AND EDUCATIONAL

INTELLIGENCE

Oxf ORD - Full term commences on Saturday, October 17, The following lectures in science generally have been advertised -

The Savilian Professor of Geometry (J J Sylvester) will lecture on surfaces of the second order, illustrated by the models with which that department has been supplied at the request of the Professor

The Professor of Astronomy (Rev C Pritchard) proposes to lecture on the methods of determining astronomical constants, and offers practical instruction with the transit circle and solar spectroscope Rev Bartholomew Price (Sedleian Professor of Natural

Philosophy) lectures on hydromechanics
The Professor of Experimental Philosophy (R. B. Clifton) will lecture on electricity, and instruction in practical physics is offered by Mr. Walker and Mr. Hatton at the Clarendon offered by Mr

offered by Mr. Walker and Mr. Hatton at one Custension Lalioratory. Tectures in mechanics and experimental physics are offered by Rev. F. J. Smith, at the Millard Laboratory. The Waynfere Professor of Physology (J. S. Burdon-Sanderson) will lecture on the subjects required for the final examination in the School of Physiology, and Mr. Dixey will lecture on the school of Physiology, and Mr. Dixey will lecture on the School of Physiology, and Mr. Dixey will lecture on the school of Physiology, and Mr. Dixey will lecture on the school of Physiology, and Mr. Dixey will lecture on the school of Physiology.

tion in the School of Physiology, and Mr Dixey will fecture on histology Practical instruction on this latter subject will be given by Mr Kent In the subject of Chemistry, the Waynflete Professor (W. Odling) will fecture on animal products, while the Aldrichan Demonstrator (W. W. Fisher) will give a series of fectures on

Dimonstator (W. W. Fisher) will give a series of lectures on the non-incidial celements. Mr. J. Wattis lectures on organic chimistry, and the instruction in pizaclical work is under the supervision of Mr. Watts, Mr. Vicey, and Mr. J. E. Marsh. The Depaty Linacer Piofessor of Human and Comparative Anatomy (E. Ray I ankestey) offers a course of lectures on comparative anatomy and embryology. This course is intended for seniors. There will viso be, a junior course for beginners and candidates for the preliminary examination in animal morphology conducted by the Deputy Linaure Professor and Di W B Benham This last-named gentleman will also lecture on the Chatopoda

The Professor of Geology (A. H. Green) offers two courses of lectures, one on physical, the other on stratigraphical

The Reader in Anthropology (E. B. Tylor) will lecture on the origin and development of language and writing The Sherardian Professor of Botany (S. 11 Vines) lectures,

this term, on elementary botany
The Hope Professor of Joology (J. O Westwood) lectures and gives informal information upon some of the orders of

Arthropoda
In the department of medicine, Sir H W. Acland, Bart gives informal instruction on modes of medical study. instruction is given at the Museum, where arrangements will be instruction is given at the Museum, where arrangements will be made for one or more demonstrations in illustration of subjects bearing on public health Dr. Collier and Mr Morgan give demonstrations for the Professor on Medical and Surgical Pathology. The Lichfield Lecturer in Clinical Medicine (W defining and the control of the cont

course of lectures on human osteology, and a series of dem

course of lectures on human osteology, and a series of demon-strations will be arranged to meet the requirements of those working in the department. The dissecting room will be open duity for precisits work and instruction ford College, has been nominated Vice-Chancellor for the enasing year. A mathematical fellowhap has been awarded at Merton College to Mr. Arthur Lee Dixon, B.A., formerly scholar at Worcester College. Mr. Dixon was placed in the first class both at Moderations and in the final Mathematical Schools. It obtained the Journ Mathematical Schools in 1897 and the Senior Mathematical Scholarship in 1891. Also at Corpus Christi College a mathematical fellowship has been awarded to Mr. Arthur Ernest Jolliffe, scholar of Balliol College. Mr. MY Arthur Ernest Jolline, scaoiar of Balioi College. MY. Jolliffe was placed in the first class by the Mathematical Mode-rators in 1889, and in the first class by the Examiners in Scientias mathematicis et physicis in 1891. He also obtained the Junior Mathematical Scholarship in 1889.

CAMBRIDGE,-The erection of the Newall telescope is nearly completed Prof Adams was able to use it for the first time last week, and took an observation of Neptune.

Prof Ewing announces that the new Engineering Laboratory is ready for use, and will be occupied this term
Mr. F. Blackman, of St. John's College, has been appointed

Mr. F. Blackman, of St. John's College, has been appointed Demonstrator of Bolany.

By the return of Prof Jebb, the University enjoys the distinction of being represented in Parliament by a Senior Classic (Dr. Jebb) and a Senior Wrangler (Sir G. G. Stokes).

Sixty-four candidates entered for the examination in sanitary science held last week. Of these forty three have passed both parts of the examination, and receive the diploma in Public

Health The Lecturer in Geography (Mr Buchanan, F R S) will this term lecture on physical and chemical geography, with especial reference to land surfaces and their development under

especial reference to land surfaces and their development under climatic and other agencies

The vote in the Senate on the question whether a syndicate shall be appointed to consider alternatives for Greek and Latin in the Previous Examination will be taken on Thursday, October 29, at 2 p.m.

University Extension —It is announced that Mr T. D. Galpin, of the firm of Cassell and Co., Limited, has offered to the Dorset County Council the sum of £1000 to be invested for the surfect county council the sum of £1000 to be invested for the purpose of providing scholarships to send natures of Borset to the Summer Meetings of Oxford and Cambridge The scholarships will be awarded to the writers of the best essays, and it is proposed that the examination should be conducted by the University Extension Committee of the Oxford Delegates of Local Examinations. The scholarships are to be awarded without distinction of sex, or any political, sectarian, or social distinction whatever

SCIENTIFIC SERIALS

THE American Journal of Science, October 1891 Some of the possibilities of economic botany, by George Lincoln Goodale. This is the Presidential address delivered before the American Association for the Advancement of Science, at Washington in August last.—On the ritality of some annual plants, by T Holm.
The author cumerates several species of plants which show a tendency to vary from annual to biennial or perennial.—A tendency to Vary troot annual to incensial or perennial,—method for the separation of antimony from anceine by the simultaneous action of hydrochloric and hydrochloric acids, by F. A. Gooch and E. W. Damner —Notes on allotropic silver, by M. Carey Lea The blue form of allotropic silver is mainly considered. The action of light on this form is remarkable, for its effect is first to increase the sensitiveness to reagents and then to completely destroy it. This reversing action is analogous to that which light exerts upon silver bromide. Mr Lea has also examined the point as to whether in the reduction of silver, the examined the point as to whether in the reduction of salver, the allotropic or the normal form is produced, and he finds that when the silver passes from the condition of the normal salt or oxide to that of the metal, the reduced silver plays appears in the ordinary form. But when the change is first to sub oxide or to orunnary norm. But when the change is next to sub oxide of to a corresponding sub-sait, the silver presents itself in one of its allotropic states.—Structural geology of Steep Rock Lake, Ontaro, by Honry Lloyd Snyth.—On the so called amber of Cedar Lake, North Saskatchewan, Canada, by B. J. Harrington. The ream or "retimite" examined by the sattlor had a hardness

of about 2'5, and a specific gravity 1'055 at 20° C. An analysis gave for 11s composition, carbon 80'03, hydrogen 10'47, and oxygen 9 50—Geological horisons as determined by vertebrate fossils, by O. C. Marsh. The method of defining geological fossils, by O, C. Marsh. The method of defining geological horzona hy vertichnet (ossils was first used by the author in 1877), and appears to afford the most reliable evidence of climatic A section accompanies the paper representing, in their geologi-cal order, the successive strata at present known with certainty from characteristic vertichrate fossils.

THURSDAY, OCTOBER 22, 1891

RUDOLF VIRCHOW AND HIS COUNTRYMEN

THE German people are to be congratulated on the brilliant way in which the seventieth birthday of Prof Virchow was celebrated last week in Berlin 'We say the German people, because the entire nation associated itself with the scientific societies in doing honour to the illustrious investigator of whose achievements it has for many a day been so justly proud Everyone who devotes the slightest attention to science is aware that Prof Virchow occupies a prominent place among the foremost intellectual leaders of the present age. As the Times has said, "So much has he done, and so thoroughly has he done it, that it is difficult for this generation to apprehend the full magnitude of his work Open a book on medicine, and especially any volume on pathology, composed, it matters not much where, before Virchow began his observations, and compare it with one composed with the light of his endless investigations to guide the author a veritable revolution in conceptions and terminology has taken place, at every turn you read, 'All this is understood since Virchow wrote,' or words to that effect, and you are referred to his inultifarious 'epoch-making' articles scattered through many professional and technical periodicals" By his great principle, "Omnis cellula ex cellula," he made a contribution of the highest importance to biological science, and his conception of cellular processes introduced wholly new and most fertile ideas as to all the phenomena of disease The science of pathology as it is now understood and taught we owe, indeed, mainly to his insight and labour, and the recent advances which have been made in it by other explorers have been made on the lines he has traced If Prof Virchow had done nothing else for science, this alone would have secured for him imperishable fame. but his energies are so varied that it has been impossible for him to content himself with one department of re-As a student of archæology, ethnology, and anthropology, he is hardly less eminent than as a nathologist. In all these sciences he has marked an era by his writings, and by the personal influence he has exerted on the Berlin Gesellschaft fur Anthropologie, Ethnologie, und Urgeschichte, which he founded in 1869 In practical life, too, as a member of Parliament and of the Municipal Council of Berlin, Prof Virchow long ago made himself a great power in Germany. He has missed no opportunity of expounding the laws of public health, and of insisting upon their importance, and a striking testimony to the value of his work in this direction may be seen in the improved sanitary condition of the German capital

To the Germans it seemed perfectly natural that, when so illustrious a man of science completed his sevenieth year, the nation should offer its congratulations on the splendid results he had accomplished Would an English man of science of corresponding intellectual rank have received similar tokens of popular gaitatide/jahl respect? Unfortunately, the question answers itself, and it would be well worth the while of Englishmen to consider carefully the causes which have led to the contrast in this respect between them and their German kingfolk. It

may be said that Germans are more demonstrative than Englishmen, but this by no means accounts for the very different ways in which scientific discoverers are treated in the two countries. The real root of the difference hes in the fact that the importance of science is much more highly estimated in Germany than in England, and especially by the Governments for several generations, the various German Governments have done everything in their power to foster scientific investigation. With this object in view, they have spent money freely and wisely, allowing themelyes to be guided, not by impulse or caprice, but by the advice of men of wide experience and knowledge were quick to note the influence which might be exerted on industrial development by technical education, and the result is that Germany has for some time had as in inv technical schools and colleges, adequately equipped, as are necessary for her wants. We need scarcely say how very different is the spirit that has hitherto animated our own Government. The idea of most English statesmen about science seems to be that it is a bore and a nuisance, and that the less they have to do with it the better for themselves and the public. Liven for technical instruction they declined to in the provision, until, by an accident, the present Government found itself in possession of a fund which it did not know how to get rul of except by giving the County Councils authority to use it for the establishment of technical schools and classes Is it surprising that when their rulers act in this way the mass of the British people should be utterly indifferent to scientific progress? The Germans have been accustomed all their lives to see science encouraged, and all classes learn therefore to regard it as an essential factor in the evolution of their national life this week they have had a fresh example of the respect in which science is held, the Emperor having appointed Prof Helmholtz a member of the Privy Council, with the title of Excellency In the telegram announcing to Prof Helmholtz the honour conferred on him, the Emperor took occasion to refer with pride to the lustre shed on Germany by his scientific achievements. Nothing of the kind is ever done here

The influence of education must also, of course, be taken into account. There is still some dispute in Germany, as in other countries, about the exact place which properly belongs to science in general education, but there is no dispute at all as to the importance of training children to recognize the benefits which science in all its branches has conferred on mankind, over in the "Realschulen" an excellent scientific training is provided for those who either have little power of appreciating classical literature, or who are likely to be best fitted for their future work by the study of science And in elementary schools an effort is everywhere made to interest children in the facts and laws of nature, and to give them some conception of the objects and methods of scientific inquiry. How far we lag behind the Germans in these respects all true "educationists know We have made only a beginning in the use of science as an instrument of popular culture, and many years, we fear, may pass before we shall have applied it sufficiently to render scientific conceptions a really vital element in the intellectual life of the community.

It is not for the sake of men of science that we desire to see more widely diffused an intelligent appreciation of their work A celebration like that of last week necessarily brings with it sad as well as happy reflections, "After all," said Bluntschli, the famous jurist, on a like occasion, "it is an end, not a beginning" Prof. Vnchow is fresh and vigorous, and the world may still reasonably expect from him much sound work, but we may be sure that, in responding to congratulations, he had a little of Bluntschli's feeling, and it is possible that, if he had consulted his own wishes only, he would have preferred to celebrate his seventieth birthday more quietly. But it is good for a nation to express on such occasions the admiration and reverence excited by a long and great career. The mere fact that men desire to honour one whose title to distinction is that he has advanced human knowledge proves that they have interests higher than those of a material character, and it inevitably tends to deepen and strengthen the best and most enduring of their unpulses We should be glad, therefore, if Englishmen had as strong a wish as Germans to display a hearty appreciation of the triumphs achieved by their great scientific thinkers That would be the most effectual of all proofs that they had begun, as a people, to understand how momentous is the part which science has played, and must continue to play, in the modern world

586

I-LECTRIC LIGHT FITTING -GOOD AND BAD

Llectric Light Fitting a Hand book for Working Electrual Engineers. By John W Urguhart (London Crosby Lockwood and Son, 1890)

THIS book is exactly what it professes to be-a practical book for practical men--and is vastly superior to "Electric Light," by the same author The detailed instructions given in the first 42 pages, on the erecting, managing, and repairing dynamos, are admirable, and are not to be found in any other book in the English language The young electrical engineer will find just the information he needs how to fit up a large dynamo when received in parts from the makers, how to prevent the commutator becoming rough in use, exactly what to do if it be rough, how to prevent sparking at the brushes. how to attach a new commutator and make joints in the armature wires; what to do if the dynamo heats; and how to get over the various other difficulties met with in the dynamo-room

The author, in these early chapters, and indeed throughout the book, uses the expression "constant current" for direct current, and although the action of the regulators of the Brush and of the Thomson-Houston constant current dynamos is correctly described, and clear illustrations given of their construction, the reader is left in the dark as to the exact use of these regulators. Or, rather, the only definite statement as to the function of the Thomson-Houston -regulator, that it is "for causing the machine to evolve more or less current as required. is certainly much more likely to lead the reader wrong than right Further, to say that "in Siemens's alternator, or the Ferranti dynamo, 'lead' must be given to the brushes"

alternate machines have no commutators, but only collecting rings), will probably destroy the correct impression about lead which the practical man may have derived from reading the previous page

OCTOBER 22, 1891

In spite of these defects, however, chapter i, is excellent, but we cannot speak quite as highly of chapter ii., "On Localizing Dynamo Faults, and Observations respecting Accumulators." In describing the test for the existence of leakage between the iron framework and the earth, the author makes an error that we have met with before, in stating that a deflection of a galvanometer whose ends are connected respectively with the iron framework and the earth indicates leakage between these two. This is equivalent to saving that a conductor not having the potential of the earth proves that it is in connection with the earth In the "Hints to Accumulator Attendants" there are some very useful suggestions, but the instructions for deciding when an accumulator is charged confirm the impression we gave when reviewing the author's "Electiic Light," that the author had not derived his knowledge of storage cells from a practical acquaintance with them. For he says that they must not be so much discharged that they cease to give any current; and in the chapter on "Switch Board and Testing Work," that the E M F of accumulators, in discharging, should never be allowed to fall below o s volt per cell. Such instructions are about as useful as saying that a horse should not be worked until he dropped, for if accumulators were to be regularly discharged until their E M F fell to a value even three times as great as the limit prescribed by Mr. Urguhart, they would be speedily ruined

Why these two statements about the discharge limit of storage cells should be given in different parts of the book, with information about "Running Dynamos in Parallel." the "Periodicity of Alternators," &c , inserted between, we do not know. In a somewhat similar way, the author returns again and again in different parts of the book to the subject of insulation resistance Lach time, no doubt, valuable information is given; but why not have put it all together, so that the working electrical engineer could have at once read up the subject, without having to turn up a number of references. This sort of scattering of information runs through the whole book, and rather suggests the idea that no very serious attempt was made to sort out information written down by the author as it occurred to him at different times.

We do not think that the explanation on p. 54-"alternators work according to a 'phase,'" is very lucid, Further on, the author says the number of phases per second is the periodicity, and later that periodicity and phase are the same thing. On p. 51 we are told "a fall of five volts in a hundred affects the brightness of the lamps,' from which a person might easily obtain the wrong impression that a fall of two or three per cent. was not observable, and be astonished when he read, on n. 72, "that a fall of five volts in a hundred in the working pressure will cause lamps which burn brightly at a hundred volts to become very dull." He would also not be able to reconcile the statement, "upon well conducted systems the pressure upon the mains is never allowed to vary more than one-half per cent.," with the variation of 2 per cent. up and 2 per cent. down, which is allowed (an instruction, of course, quite impossible to carry out, as | by the Board of Trade Nor is it possible to understand the rule with reference to the wiring of a house, "It should show an insulation resistance of at least 1 meg-ohm per lamp," since this would make the insulation of an installation the higher the greater the number of lampholders, whereas of course, as a matter of fact, the very reverse is the case.

Chapter iv. on "Arc Light Wiring and Fitting," is full of practical suggestions: the instructions on the trimming of arc lamps, and the precautions that ought to be adopted in order to keep arc lamps in good working order, will greatly help the young engineer when he is first put in charge of arc lamps It is a pity, however, that when the author is speaking of supplying constant current to a variable number of arc lamps running in series, he should say, "but the shunt or compound-wound machines are supposed to regulate themselves, which they very often fail to do " For we never heard of a compoundwound machine, still less of a well-made shunt machine, which professed to produce a constant current when the external resistance was varied. And this mistake is emphasized in the next section, on running arc lamps in parallel, since, although it is quite rightly said of the attendant, that "his chief care is to keep the potential difference between the leads the same," Mr Urquhart states, "This is usually effected in part by the dynamo itself when a shunt-wound machine is used, or by regulating the speed", and he makes no reference here to the use of a compound-wound machine, as if it were not the special function of this type of machine to keep the potential difference between the mains constant.

There is a good illustration on p 107 of the Thomson-Houston lightning arrester, with an explanation of its construction, but no hint is given that the electric arc produced by the lightning flash is magnetically blown our and thus extinguished And in the large perspective illustration of a Thomson-Houston transformer, given in this chapter, the thickly insulated leads are shown with a thick copper conductor inside them, while the lightlyinsulated leads have a thin conductor, and since, in the description of a transformer, it is not stated that, besides transforming from a high to a low potential difference, this apparatus also transforms from a small to a large current, it would be quite possible for a beginner to read this book, and wonder why people went out of their way to construct dynamos to produce one or two thousand volts, and then had to employ special apparatus at the consumers' premises to lower this high potential difference. "It is usual to put the secondary circuit to earth," probably expresses the author's view (as it also does the reviewer's) of the proper way to guard against accidents being produced by a contact between the primary and secondary circuits of a transformer, but it certainly does not represent the ordinary practice.

The name "impedance coils" is suggested for inductive coils used to diminish a varying or an alternating current; but the necessity for this name arises from the expression "choking coils," which is commonly used in this sense, having been wrongly employed by the author for any kind of resistance coils, such as, for example, a non-inductive restance used with a steady current.

Chapter v., on "Wiring for Incandescent Lamps," abounds in useful hints, and is illustrated with several NO. I 147, VOL. 44

well-executed woodcuts. Admirable, however, as may be the switches, fuses, &C., constructed by Messrs Woodhouse and Rawson, the succession of illustrations with the names of that firm underneath tends to give the impression that there are no other manufacturers of such apparatus. Surely the weighted fuses made by the Acme Works, the switches of Messrs Stemens—which provide a metallic circuit for the current but expend the flash, produced by opening the circuit, on carbon contacts—and the switches of Messrs Crompton, were worthy of a reference

If the well thought out precautions detailed in " Methods for Running Wires" had been followed in all the wiring of houses that has been carried out during the past few years. we should not have heard of those very justifiable complaints of occupiers who, after taking the lease of a house, temptingly described in the agent's list as fitted throughout with the electric light, find that they have to entirely re-wire the house before the insurance office will allow the current to be turned on. We thoroughly agree with the author that " There is one leading maxim for a contractor putting in electric light, and it is to avoid contracts that do not allow of the best class of material and labour being used throughout" We should also like to impress on the general public that the plummer, or the carpenter's handy man, is not, as they seem to think he is, any more capable of fitting up an electric installation than he is of setting a broken leg

We do not understand why, as a definition of "cleat wiring," Mr Urquhart says, "This means uncovered wires run &c " . surely cleats are ficulently employed to hold down covered as well as uncovered wires. On p. 185 the temperature is not stated at which "the ohm is the resistance offered by a column of mercury 1 square millimetre in cross section and 106 centimetres long." Power and work are said to be synonymous, and footpounds said to be analogous with volt-amperes output of 1000 watts "is called under the Board of Trade regulation a kelowatt," whereas the late Sir William Siemens, and not the Board of Trade, originated this name "As lamps are now made, each would probably give a light of 20 candle-power, the watts per candlepower being 2 5" Would that we could buy glow lamps which had a decent life, while needing only 25 watts per

Sir William Thomson's rule about the right sectional area to give to a conductor "is only a suggestion made for the protection of buildings from fie." We thought everyone knew that it was a rule for settling the thickness of the conductor with which maximum economy could be obtained

The rules about jointing leads are exact and valuable, we do not, however, like the general rule of using the body of a chandeher itself to serve as the return, and we think this rule ought to be followed only when the return were is throughout the installation an uninsulated one

Chapter vi. gives a good risumi of the prov and contregarding the use of the body of an iron ship as the return for ship lighting, while chapter vii. gives the substance of the rules issued by the Institution of Electrical Langineers, in connection with fire risks and danger to life.

MORE SUGGESTIONS FOR COUNTY COUNCILS,

County Councils and Technical Education By J. C Buckmaster (London Blackie and Sons)

U NDER the above tule Mr Buckmauter, who for turer, and organizer with the Scenec and Art Department, gives some statistics relating to technical education, and his views on the best way of utilizing the funds in the hands of County Councils. We need hardly say that, backed as they are by so long an experience, his opinions deserve the most careful and respectful consideration.

Briefly stated, Mr. Buckmaster believes in class teaching as opposed to lectures, and in utilizing as far as possible existing elementary and science and art teachers. "Unless," he says, "the sympathy of teachers and other educationists can be enlisted, the most carefully considered schemes of County Councils can only end in partial or complete failure." Again.

"Lectures by themselves are never to be highly valued as a means of ductation in all electure on science, to create and sustain an interest, you must be popular, and to do this you awould the complex difficulties of the science, which are often the only intellectual parts of P. Lectures, unless followed up by thought and reading on the part of those who hear them, fall as a means of education, &c., &c."

All this is excellent, and the warning is useful. But when Mr Buckmaster comes to the application of these principles he is not quite so happy. For example, he is unjust to the University Extension system, which he does not clearly understand, and treats as though it were mere popular lecturing, like the work of the old Mechanics Institutes Now, though we have no belief that the University Extension machinery can fill the place of elementary class teaching, we cannot accept the implied suggestion that courses of ten or twelve lectures (often arranged in sequences of two or three sets of twelve lectures), each lecture followed by a class for the more serious students, and by written paper work corrected by the lecturer, and the whole course tested by independent examination, form an engine of instruction scarcely above the level of a clever conjuror's performance

His constitutive suggestions are, first, to use elementary teachers to give object-lessons in simple science -a most useful proposal, about to be carried out in various counties as soon as the teachers themselves can be properly trained for the work, and secondly, to multiply science and art classes "The best technical instruction for some time will be a wider development and extension of the educational work of the Science and Art Department by means of night classes and continuation science and art schools" This depends, of course, on the meaning to be attached to "development." If it merely means multiplication, the statement is open to serious question No one can know better than Mr Buckmaster the special dangers attaching to the system which he advocates? the abuses which grow up round a system which makes the financial success of the class, and usually the salary of the teacher, depend on the result of an examination In our opinion, the machinery of the Science and Art

Department will long continue to be a most useful and important factor (though not to the exclusion of other agencies) in the development of technical instruction. But the present is the great chance to consolidate and improve, rather than merely extend the work. If the County Council funds are so granted as to correct the evils which inevitably arise out of s ch a system of payments on results as is adopted by the Department-if its control is used to render more effective the inspection as opposed to the mere examination of science and art classes-then the portion of the grant given to promote the work aided by the Science and Art Department will be well spent But no claim on the part of this or any other single agency to a monopoly of all technical instruction above the rank of that which can be given by the village teacher can be conceded. Mr Buckmaster does not in so many words make the claim, but he sometimes seems to imply it by minimizing the value of most other experiments which County Councils are attempting It is virtually a plea for educational bureaucracy against local experiment. But we have not yet reached the stage, if, indeed, we ever do so, when variety of experiment can be dispensed with. Some of the experiments will probably fail. But it is only by wide and free experimenting that the "fittest" will be discovered Mr Buckmaster has confined himself, probably on purpose, to the elementary branches of technical instruction, and is silent on its higher developments. Manual work he only just mentions, and not with much sympathy criticisms on the wood-carving taught by ladies in villages is not, perhaps, too severe, but it is strange that he does not give a hint that systematic manual training may be (as it has been for a long time in other countries, and lately in our own) made of real educational value a word is said of the worst defect of all in our educational system the want of good, cheap, secondary schools, which the present grant may do so much to icmedi

Though, however, Mr Buckmaster takes a rather cramped and narrow view of the outlook, his pamphlet is full of valuable, if rather partial, ideas

The pamphlet opens and concludes with some useful statistical and other information taken from various publications of the National Association for the Promotion of Technical and Secondary Education Readers who not know the source from which these pages are derived may be puzifed by a reference to "the Committee" (p. 41), which by some error in editing has been left still standing, without explanation, in Mr Buckmaster's pamphlet.

THE MISSOURI BOTANICAL GARDEN.

Missour: Botanical Garden Second Annual Report. By William Trelease. Pp. 188, Plates 48, reproduced Photographs 5, and Plan of Garden (St. Louis, Missour: Published by the Board of Trustees, 1891.)

THE Board of Trustees of the Missouri Botanical Garden have instructed the Director to edit for publication each year a volume setting forth the objects of the Garden and the School of Botany, and the results accomplished by each. The first volume of this series was issued in December 1890, and contained an account

of the Garden and School The present volume, therefore, really begins the series of annual reports, and together with the reports we have a revision of the North American species of Epilobium. In the earlier part of the book details are given of the appointment of six garden pupils to scholarships in accordance with a resolution adopted by the trustees at a meeting held in November 1889 Each scholarship conferred may be held by the recipient for a period not exceeding six years, subject to certain conditions. The holders of scholarships are renaid for their services to the Garden, and at the expiration of the six years are entitled to examination by the Garden Committee On passing such examination to the satisfaction of the Committee and Director, they receive a certificate of proficiency in the theory and practice of gardening The only scientific paper in the volume is, as we have just mentioned, a revision of the genus Epilohium, the American species occurring north of Mexico being those studied This genus differs from all the other capsule-bearing Onagracca, except the Califorman Zauschnerm, in having its seeds provided with an ample coma at the apex. While it reaches great development in New Zealand, Epilobium is essentially a genus of temperate and cold climates, and the most widely distributed species are those of Arctic and Alpine regions In Alaska a few such species occur, which are otherwise confined to the adjacent part of Asia More widely distributed Arctic-Upine iminigrants from the Old World to the New are E spicatum, E latifolium, E palustri, F alpinum, &c E hir sutum, E parvissorum, and E adnatum, also occur as accidental waifs. The genus passes into South America along the backbone of the continent, few members of this family extend very far across the Mexican boundary in either direction. The most interesting biological features of the genus are those connected with the means of vegetative propagation, pollination, and dissemination The contrivances by which species survive the winter. and are vegetatively propagated, in this respect attain an extreme degree of differentiation, one in particular having acquired aerial bulblets. The large flowered species appear to be regularly proterandrous, the duration of the dichogamy being brief in most of them, and the smallerflowered seem to be always synactic and self-fertile, although with the probability of frequent intercrossing by aid of insects attracted by the nectar which is secreted The genus is of no striking within the cally tube economic value The North American Epilobia have been mostly described by De Candolle, Torrev and Gray, Haussknecht and Barbey, the more notable works of more limited range being Hooker's "Flora Boreali-Americana," and Brewer, Watson, and Gray's "Botany of California," Prof Trelease in his revision enumerates 38 species, which number includes the following novelties . E holosericeum, E delicatulum, and E clavatum The well-known sections Chamanerion and Lysimachion are still adhered to, the latter, of course, being by far the larger In the analytical key the main divisions depend on whether the stigma is deeply 4-lobed or 4 cleft, or entire or only notched. Subdivisions are founded on whether the seeds are smooth, or papillately roughened The name E spicatum, Lam, is used instead of angustifolium, the typical angustifolium of Linnæus being,

according to Prof Haussknecht, what is commonly known as L. Dodones, Vill We are glad to see that Prof Trelease differs from Prof. Haussknecht in not adopting a new name for what is left of the original E alpinum The E albinum of Linnaus included with this E Hornemanns and E anagalishfolium, but we think that the name may well stand for one of the segregates genus Epilobium has always proved a difficult subject . and Prof Trelease is to be congratulated on his careful treatment, and successful arrangement, of the North American members The 48 plates will be found of great help to students of these plants, they are not quite of uniform merit, but, taken as a whole, they give the essential details, stress being laid on the varied form of the stigma and seed Additional illustrations are some well-reproduced photographs taken in the Garden, and a plan of the grounds (scale - ! a) in five sections

OUR BOOK SHELF

The Story of the Heavens By Sir Robert Stawell Ball. Eighteenth Thousand (London Cassell and Company, 1891)

In the preface to this edition, Sir Robert Ball remarks that he has taken the opportunity to "revise the work in accordance with the progress of astronomy during the last four years," and, generally speaking, new facts and theories are briefly referred to A few points, however, are hardly brought up to date For example, the spectium of the Andromeda nebula is said to be "a faint continuous band of light" (p 462), although it is now definitely known that this continuity does not exist We also find no reference to the many stars now known to have bright lines in their spectra. The author thus misses a chance of exercising his well-known descriptive ability in an account of the connection between such stars and nebule, the similarity of the two being so considerable that Pickering has followed Lockyer in arranging them in a single group. Dr Huggins's old view as to the coincidence of the nebula line with nitrogen is mentioned merely to be dismissed as erro-Why, therefore, is no notice taken of the suggested magnesium origin of the line—for, on any published evidence, the edge of the magnesium fluting is nearer the proper position than the nitiogen double? We would also point out that, according to recent observations, the apex of the sun's way is much nearer Lyra than Hercules Telescopic changes in comets are fully described, but the accompanying changes in their spectra are not touched upon. Motions of stars in the line of sight are considered; but not those of nebula, although Mr. Keeler's observations have been published for some In fact, it may be said that there is a tendency ume to eschew spectroscopic questions, and hence much of the most beautiful part of the story of the heavens is left untold.

Notes on Elementary Physiography By Horace C Martin. (London and Manchester John Heywood, 1891)

THE author has collected a lot of scraps of information from standard writers on physiographical matters, and has strung his gleanings together to form this book. And if he were an adept at compilation, and knew how to best arrange and connect facts, his plan of printing extracts verbatim might be commended. But when Mr Martin selects noise which by themselves are incorrect, and inter-

polates in others crude statements which render them redeculous, he does an injustice to the authors to whom he acknowledges his indebtedness, and he shirks responsiacknowledges his indededeness, and he sarris responsi-bility by saying that "these notes do not lay claim to originality" Could anything be more misleading than the following description of sun spots on p. 148? "They seem to rise suddenly to a great height, cool, and then sink back into the photosphere They are due to up-rushes of incandescent hydrogen, and are identical with the red flames seen during an eclipse." And the figure that accompanies this text cannot be a sun-spot at all, but must be something else inserted by mistake. Another blunder occurs on p 50, where a section of an intermittent spring is shown upside down. The figures are mostly very coarse and poor, especially the moraines on p 62, the section through a cinder cone on p 89, and one of a volcano on p 90, whilst the two figures of ocean bottoms on pp. 102 and 103 give a very wrong idea of their nature. There is, of course, a deal of information in the book, but no attempt is made to give it interest. In fact, although the author is a teacher of physiography, it is very evident from his work that he has not paid attention to the practical side of his science, or verified any of the phenomena he essays to describe As a book of reference the work before us is untrustworthy; and as a work for students of elementary physiography it is useless and much to be condemned

Thomas Sopwith, M.A., C.F., F.R.S., with Excepts from his Diary of Lifty wen Years. By B. Ward Richardson, F.R.S. (London Longmans, Green, and Co. 1891)

MR SOPWILL died in 1870 at the age of seventy-six. He was not eminent as an original scientific investigator, but was not emment as an original scientific investigator, but he was a man of great tugor and freehness of mind, and had won the affection of a wide circle of friends by his genal and happy temper. For many years he reasted at Newcastle as an eigeneer and tailway surveyor Afterwards he removed to Alienheads, where he served as the chief agent of M. T. W. Beaumont's lead-mines in Northumberland and Durham Dr. Kudandson's book will recall Mr. Sopwith vividly to the minds of his book win retail at rought any things which will be of interest even to readers who were not personally acquainted with him Duning the long period of fifty-seven years he kept a diary regularly, and of this, of course, Dr Richardson has made liberal use. The extracts show that Mr Sopwith studied closely the currents of scientific opinion, and formed his own judgment about them in a shrewd and independent spirit.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions ex-pressed by his correspondents. Nisther can he undertake to return, or to correspond with the winters of, regated manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

Electric Transmission of Power

Your article of the 1st inst. on the International Flectrical Ex-bition (p. 522), says. "In those days (before 1879) two wrong hibition (p. 522), says. "In those days (before 1879) two wrong notions misled people—the one, that the maximum efficiency of a perfect electromotor could be only 50 per cent; the other, quoting the remarks of Sir W. Siemens, 'in order to get the best effect out of a dynamo electric machine, there should be an external resistance not exceeding the resistance of the wire in the machine

These two notions are really one the first follows by immediate inference from the second.

Your article says a little further on . "At the British Associa-

tion in 1879, Prof. Ayrton exposed the fallacy of assuming that 50 per cent. was the maximum efficiency theoretically obtainable from an electromotor. This was perhaps the first time

NO. 1147, VOL. 447

that it had ever been suggested that the efficiency in electric transmission of power could be more than 50 per cent."
This is a markle as to instroid afet. Many years ago, I am a markle as to instroid afet. Many years ago, I am a mirror of the property to which he replied, "The maximum effect, in Ohm's theorem, does not mean the maximum work done by the oxidation of a given quantity of zinc, but the maximum effect obtainable from a given surface of zinc plates?" "I see," said I, "just as in the case of the steam engine, the problem of getting the maximum effects of the steam engine, the problem of getting the maximum engine. mum of useful effect from a given weight of coals is a different one from that of getting the maximum of power from a given area of useful.

This appears to be an instance of a truth being grasped by one of the great masters of science long before it passed into general teaching. And it is also an instance of a truth being so mistaken as to mislead. Ohni's law was evidently understood.

to bear a significance that it did not really bear
Belfast, October 13 JOSEPH JOHN MURPHY

[I hat Joule had clear and correct views regarding the efficiency [Lihat Joule had clear and correct views regarding in enuncincy of an electromotor driven by a voltaic battery was pointed out some years ego, being mentioned, for example, by Prof. S. P. Thompson in his book on "Dynamo Electric Makinney" But in the paragraph quoted by Mr. Nurphy from NAIVER of Cytober 1, the expression "electric transmission of power" had October 1, the expression "electric transmission of power" had reference to the combination of apparatus exhibited at the lecture in question—had, in fact, the meaning usually attached to this expression, wir the employment of a dynamic to convert mechanical energy into electric energy at one end of a pair of wires of some length, and the employment of a second dynamo at the other end of the wires to convert the electric energy back again into mechanical energy

Now, not only would it have been somewhat difficult to foretell what would be the combined efficiency attainable by the employ-ment of two dynamos as generator and motor, at a period " long before the dynamo was invented," but even down to 1879 no one had succeeded in practically transmitting power by means of this combination with an efficiency of as much as 50 per cent over a distance of even one mile

The only direct current dynamo in common use at that date was the series dynamo, and that machine, as is well known, differs radically in its behaviour from a voltaic battery. For while it is when a voltaic battery is developing a very small white it is when a voltate battery is developing a very small current that it gives power most economically to the outside Circuit, the senes dynamo, when only a very small current is passing through it, develops practically no electromotive force, no power, and therefore has a very low efficiency. Hence, although electricians were undoubtedly mistaken in facejung that there was a theoretical limit of 50 per cent. In the efficiency when two dynamous were employed in the transmission. of power, neither the error, nor us correction, were of that obvious character in 1879 that one might imagine from reading Mr Murphy's letter,—W. E. A.]

Rain-making

In 1883 I published in Narvara (rol. xavisi., p. 83) an account of some experiments which I made to explain the account of some experiments which I made to explain the curious phenomenous commonly seen at the Bocco of the Solitatra and the action of the flams, even when it direction has been and the action of the flams, even when it direction has been very brief, is observed for some time after in the relatively great increase of cloudy support that appears to roll out of the Bocco and to rate from the surrounding insort unarroles. According you want to the contract of the contract of the second through the second to the contract of the second to the sec cloud or mist) the increase of solid corpuscies made to float in

the vapour-laden air inside or near the fumarole, might be the cause of a rapid and continuous condensing of the invisible vapour. I noticed that the "powdering" of the air with any kind of dust increased the cloudy column issuing from the Bocca of the Solfatara. I am therefore led to believe that the Bocca of the Somman, I am therefore led to beneve that the action of a paper- or faggot-flame in causing the increase of visible vapour from the Bocca of the Solfatara is due both to the production of carbon dioxide and to the increase of solid particles of soot and of light unburnt figurents made to rise and float in the our

These experiments may help in explaining the action of ex-plosives in causing a downfall of rain. Not only does the explosion produce a certain amount of carbon dioxide, but dust is widely scattered in the air, and carried upwards by the hot is widely scattered in the air, and carried upwards by the hot gases produced in the explosion I fit he issuits of the experi-ments in Texas and Kanasa by General Dyrenfurth and Prof Curtus be confirmed, it would be interesting to see if the con-densation of vapour in the atmosphere could be better insured. census on trapour in the almosphere could be better hunch by purposely linerasing the quantity of dust produced in cache explosion. The effect would perhaps be enhanced if the dust were of a markedly hygoresopical nature the cattering in high air of very immune particles of calcium chloride should belig in the making of cloud and rana LAD GIGLIOL. Weather Cycles and Severe Winters

THE following view of the relations of severe winters is one

THE following view of the relations of evere winters is on-which I do not received to the seen stated. When I do not receive the three seen stated with the condition of the con

coldest of those preceding, 1870, then come (similarly) 1864

and 1860 Thus we have a succession of severe winters of decreasing severity, and another, after it, of glowing severity.

We may tab	ulate the data		
Severe wenters with lessening severity	Mean temperature	Severe wirters with growing severity	Me in temper tiure
1813	319	186o	37 4

with lessening severity	Mean temperature	with growing	Me in temper nure
1813	319	1860	37 4
1829 1840	33 2 33 9	1864	37 I
1844	. 349	1870	36 4
1846 1854	34 9 1 35 6	1878	34 6
1859	37 4	, 1890	34 I

These data, put into the form of a graphic diagram, give Indee data, put into the form of a graphic diagram, give a wave whose crest (mildest of the severe mitters) we seem to have passed in the svites. And it would appear judging by the past, that we have not yet reached the bottom of the hollow, but that after some years' interval we may have a winter even more severe than last, possibly we may have more than one, of growing severity.

growing severity, I is right to state that, as far as 1856, the values of mean temperature used are those of Mr. Belleville, reduced to sea-level, as given in a paper by Mr. Eaton to the Koyal Meteorologocal Society (Quarterly Journal, January 1888), after that date, those of Greenwich Observatory, published annually. The alight difference in kind does not materially affect the result. In the Materializate Eatherful for September, M Woekof

In the Meleoroughton collectiff to September, M. Woekol considers the question whether winters in Russia have been growing warmer, and his examination of the St. Petersburg records, from 1744 to 1890 (noting the number of cold days), leads to an affirmative answer The number of very cold days). has, on the whole, fallen off considerably in the later sixty-three

years compared with the earlier, and in the second half of our entury, as compared with the eighteenth and the earlier half of the pineteenth

of the ameteenth
This, be finds, corresponds with popular opinion for Northern
and Central Russia, according to which intense frosts have become
more rare, but in the south, in the Chimea, the Caucasis, and
Turkestan, there have been compliants of colder winters of late Mr Glaisher some time ago expressed the view that our winters

to the effect that the proximity of Greenwich to such a rapidly growing only as London might have to do with such a rapidly growing only as London might have to do with such a result. If growing city as London might have to do with such a result. If the facts are as I have suggested above, a growing severity has taken the place of growing mildness, and the criticism referred to would fail to apply.

A Lunar Rainbow

On the evening of Saturday, October 17, at about 6 30 p m . the rare and interesting phenomenon of a lunar rambow was observed from Patterdale, Westmoreland. On the south-east, the moon, which had just usen, bughtened the sky behind the mountains, while on the north west there hung a uniformly dark and unbroken screen of haze or rain cloud, which lightened off somewhat and was more scattered on the extreme west With its highest point lying almost exactly north west, a semi-circle of pale whitish light was projected against this vapoury circle of pale whitah light was projected against this vapoury curtain. The bow as quite complice, but much brighter and shapere on its northern are than on that falling south. The force of the part () KEEGAN

Patterdale, Westmoreland, October 17.

The Destruction of Mosquitoes

THE recent mention of this subject in your pages reminds me that I was told a few years ago by in English gentleman who has a most beautiful place on the Riviera that he had freed his property from this pest

The property in question is a peninsula, and for that reason is exceptionally open to separate treatment. On the Riviera, as many of your readers will know, fresh water is a somewhat lare commodity, and all of it that the inhabitants can lay hold of is stored for future use in tanks or small receptacles

The larva of the mosquito lives, as I understand, only in fresh water Consequently, on the Riviera he is found in the tanks I have named

The carp is, I am told, passionately fond of the larva of the misquito, and the Englishman I refer to had extirpated the insect by putting a pair of the fish in every tank

The plan is not one that could be adopted everywhere, but it is worth bringing under the notice of those whose circumstances are like those of the Riviera.

Law of Tensions

Possibly many science teachers find some little difficulty in POSSIBLY many science teachers had some little discully in satisfactorily demonstrating to a class the "law of tensions" for wheating strings in practice, unless the sonometer is fixed vertically, the error introduced by friction at the pulley (especially with heavy weights) is so great that the real tension is very different from that represented by the weight attached. Even if the apparatus be him fixed, the changing of the weights occupies time, and a comparison wire is necessary, which must first be luned to exact unison The following a mirable and very simple method was suggested to me by one of my students, and possibly there are some teachers to whom the idea is new

Instead of applying ten ion by attaching weights, the result may be effected much more readily by means of an ordinary spring suspension-balance, such as is often used for weighing

parcels. By this method the tension may be regulated to within half a pound, and increased or decreased so rapidly that the heightening of pitch is clearly recognized without the use of an auxiliary wire

The Koh I-Nur a Renly

Ir is a far from plea-ant task for me to set about replying to Prof Maskelyne's criticism of my history of the Koh -Nur. I desire to say what must be said with all respect for him, but the tone of some of his remarks renders this a task of exceeding tone of some of his remarks renders this a task of exceeding difficulty. All I care about is to get at the fruth, and in order to do so I have spared neither time nor labour. I cannot suppose that you would grant me space sufficient for answering in detail all the statements in Prof. Maskelyne's article, nor do I seek for such space, because I deem it to be sufficient for those, several of them experts, who have accorded my views their hearty support and approval - Firstly, to state her, in a general way that having very carefully studied Prof Maskelyne's long article it has not, in my opinion, in the very smallest degree shaken the facts I have quoted, and the deductions from them which are to be found in my appendix to "Tavernier's Travels," and in the article pub-lished in the April number of the English Illustrated Magazine lished in the April number of the Linguist Illustrated Alloquestics of the pre-ent year. Indeed, I might go further, and say that this attack very materially confirms the strength of the position upon which I have taken my stand. Secondly, I shall select a few points only which afford clear issues without any mystification, as to which said the balance of evidence hes upon, and mivite readers to draw their own conclusions

Before going further I think I should recall to notice the review of my edition of "Tavernier" which appeared in NATURE last Febinary (vol xim p 313), and the Linglish Illustrated Magazine for April, from which it will be seen that a nggestion made in the review has since been acted upon, with the result that was anticipated

Prof. Maskelyne states that there is an absence of novelty in my facts Just so, it is the old facts that I rely upon, not the miswithings. In my earliest allusions to this subject, many years ago, I made some mistakes, from blindly following authorities whom I now know to have been misted as to their facts. Since then I have learnt how necessary it is to check all statements as of fact in reference to this subject, and not to place too implicit a trust on quotations, no matter how eminent the authority who makes them may be

nixes them may be to the judicial position which Prof. 18 to Compare to occupy, to say hal. I damin Prof. 11 II. Wilson, and what he narraies, "by the somewhat dippont remark that "thas afforded undry imaginary that what has afforded undry imaginary in the lacts being these—I never referred to Prof. 11 II. Wilson; I did not even know before that he was the writer of the anonymous note in the efficial extalogue, and more than that.

I had not that particular contribution to the subject in my mind when writing the above words

Still further, with regard to the judicial position. I do not think it is apparent in any of Prof. Maskelyne's subsequent remarks They are those of an advocate who smites his opponent in season and out of season, and seeks to disparage him by implying that he has as suited the reputation of men (whom all must honour), when he has merely pointed out misquotations in their writings and expressed dissent with their conclusions

writings and expressed dissent with their conclusions.

I yield to no one in my admiration for the late Mr. King's work, but this cannot and should not restrain me from pointing out misquotations and misprints in his books when treating of the subjects with which he has dealt. To justify this I shall quote but a few instances which I have noticed, out of many, On pp 78 and 82 ("Natural History of Precious Stones," Bohn's edition, 1870) the weight of the Mogul's diamond is stated as

contion, 1570) inc weight of the Mogur's diamond is stated as on Tavernier's authority to have been 250 carats and on the plate 268 carats, instead of 379% carats. The Koh-Nur is stated on p 82 to have weighed 184 carats instead of 186 ts, and, strangest of all, when recut, that is to say in its present condition, its weight is given, pp 75 and 347, as 1024 and on the plate as 1021 carats, whereas its true weight is 106, carats

On p 68 he deduces an argument from the note by Clusius, which is referred to by Prof Maskelyne, and given in the original in my paper, the whole force of his argument depending, h

ever, on the change of the word Belgium of the original to Europe in his, Mr. King's, own rendering of it I might add to this list, but sufficient has been stated to show

that such statements require the most careful scrutiny, by whom-

diamond with the Koh-i Nur

that such statements require the most careful scrutiny, by whom-sover they may have been made

On pp 81-82 will be found Mr King's dissent from Prof Maskelyne's theory about the identity of Babar's diamond with the Mogul's, the difference of opinion between them being very wide indeed, though Prof. Maskelyne does not think it

necessary to refer to it in his article With reference to what Prof. Maskelyne writes about De Boot and Garcia de Orta, I shall only say that I am very well ac quainted with both authors' works, and that I assert again that the statement wrongly attributed to Monardes, and quoted as from Mr King by Prof Maskelyne, was an unsound and dangerous link in the chain by which it was proposed to connect Babar's

diamond with the Kohr Nur
It was a statement convenient to use, but what if I had used
it flist, and had also mispinced the authority? Would the terms
and had also mispinced the authority? Would the terms
whatever on my part, and Prof Mak-letyne has himself now
whatever on my part, and Prof Mak-letyne has himself now
whatever on my part, and Prof Mak-letyne has himself now
had the considered the profit of the profit of

exxiv , 18:6, p 247) I still venture to think that my conclusion as to the kind of I still venture to think that my conclusion as to the kind of carat used by Taveriner is a legitimate one. At the end of chapter xviii, book ii, he says, where computing from their weights the values of diamonds to a farri, "le Diamant du Grand Mogol pese 279% carati" (4a), and in the very next paragraph, "le Diamant du Giand Duc de Toccane pese 1394 paragraph,

I rue it is, as pointed out by Prof Maskelyne, that Tavernier in some other passages defines the carats as "nos carats", he does not say, however, "carats de Fiance," and the meaning does not say, however, "carats de Fiance," and the meaning therefore I take to be the carats employed by himself and his confracterinty as contracted with Indian measures of weight. The value of the abbas or peath out; of 2 66 grains, or seveneighths of the Florentine carat, has also been approximately

engines of the reference caret, nas also been approximately arrived at hy other relations given by Tavimer, conveisely, therefore, it proves his carat to have been the Florentine.

I know of several carly writers who have writen about the Grand Duke's diamond, and by them Favernier is referred to as Grand Duke's damond, and by them l'averner v referred to a the authority for its weight, which, as even Prof Maskelyne admits, was given in Florentine caratt. I think all the cir-cumstances justify the belief that it was probably weighted. If Toveniner himself with his own weights and sealer. Now level Frod Maskelyne (p. 557) Mates that l'averneric does not say be weighed any of the siones, and, in another, on the same page, "The damond l'averner saw, weighed, he said lwas he merely he diamond Tavernier saw, weighed, he said (was he merely

aniamona i awerner saw, weighed, he said [was he merely told so or did he really weight it?], 3194 ratis "
The pages of Taverner give the following very explicit answer to this query. He says, "Ce diamant appartient au Grind Mogol, lequel me fit Ihonneur de me le faire moniter avec Mogol, lequel me hi l'honneur de me le laire montrer avec cous ses autres joyaux. On vot la lorome ou il est demeuré ciant taille, d'm'ayant esté permis de le feis jay ironée qu'il fest 3164 stats qui soul 2797é, de nos carat.

This is precise evidence enough that he did weigh the stone himself, and if the caratis were 1 rench instead of the lighter

Florentine carats, which I believe them to have been, the stone was so much the heavier, and therefore still more removed in weight from Babar's stone

Tavernier, I must remind the reader, besides Beruier, is our only authority for what is known about the Mogul's stone, as such, and what I have protested against and still protest against is, the suppression or rejection of such precise statements as the

In various directions I have been enabled to show Tavernier's minute accuracy about matters not connected with his trade as a jeweller, and when he speaks as an expert, in the practice of his own profession, he deserves, and proves that he deserves, a very different treatment from that which he has received. It is for this reason, and not because I am blind to his faults, that I give him my loyal support I have already, in vol. ii. of "Tavernier's Travels," stated that some corrections of values given in vol. are required in consequence of the identification, made too late for their correction, of the value of Tavernier's creat, but the present discussion as to the Koh i Nur is quite independent of that.

With regard to the mutilated condition of the Koh-i-Nur, I

write regista to the matinatea condition of the Roh-t-Ruit, I have nothing to add, the statement as toliv condition, quoted by me, and the figures and models of the stone appear to be sufficient proof that portions had been removed by cleavage, which would account for the difference between its weight and the Mogul, as described by Tavernier, and I still retain that

opinion It is not of the least importance as regards the main question. whether my suggestion should prove correct or not, that if Bahar's stone has survived it may be identical with the Darya i Nur, to which Maleolm attributed a weight of 186 carats Prof Maskelyne, upon a system of calculation which I cannot admit as applicable to the case, as we do not know the thicknesses of the stones which he compares, gives to the Darya: Nur an estimated weight of 210 carats For the present, therefore, I prefer Malcolm's definite statement to Prof Maskelyne's theory about the attributed weight being the "echo associated with the Koh-

I shall have something to say about the Golconda table diamond, and about a great many other diamonds and other precious
stones too, on a future occasion In that work I shall be as careful sones 100, on a twine occasion. In that work I shall be as careful to give, as I have hitherto been, chapter and verse for every statement of fact quoted, and I shall must the histories so apported will find acceptance from those who care to in vestigate the evidence in favour of the conclusions connected therewith

Tam not quite sure that I appreciate the full force of the phrase "versimilitude of a true history"—the last works of Prof. Maski-june'a article—but of thir I am ceriain, that if ever I should see a history of the Koh i Nur following the these of that article, I shall feel bound to make another and special "incursions" into

Dublin, October 12 U BALT.

THE NAULICAL ALMANAC.

T has been known for some little time that Di John Russell Hind, F R S, who for many years past has been responsible for the production of the national ephemeris, would soon seek that retirement to which his long services and his distinguished career entitle him. At the end of the year, he will relinquish the office of Superintendent of the "Nautical Alamanac," and the good wishes and kindly sympathy of the astronomers of many nations will follow him in the retirement he is seeking

His successor has been appointed, and in Mr A M W. Downing we have not the slightest doubt that the Admiralty have made a happy selection, and that under his auspices the high character and reputation of the "Nautical Almanac" will be fully maintained Mr Downing has long been associated with meridian astronomy in its best traditions, and in his position of greater responsibility and greater freedom we entertain the hope that his astronomical reputation will be fully maintained and extended He may be said to enter on his office at a time when the "Nautical Almanac" is on its trial The arrangement of the book, and the information it conveys, were practically settled by a Committee some sixty years since How efficiently that Committee performed years since How emclently that committee performed its task is shown by the fact that so little alteration has been needed for so long a period. But the outcry for change has gone forth—new committees are deliberating and reporting, and it will be among Mr. Downing's first duties to give shape, alike to the suggestions of irresponsible authorities, as well as to incorporate the recommendations of recognized committees in a new and improved "Nautical Almanac."

One great difficulty which has to be encountered, and of which it is not easy to see the proper solution, is due

NO. 1147, VOL. 44

to the fact that the "Nautical Almanac" seeks to supply the wants of two very different classes of persons-namely, astronomers properly so called, and nautical men. The former demand very considerable detail in the exhibition of the several computations, the latter are satisfied with a very few final results. The former class is a small one, and a very moderate edition would satisfy their demands. The latter class is a very large one, and necessitates the printing, it may be, of thirty or forty thousand copies The first question therefore, it seems, which must claim the attention of any Committee, or of any Superintendent, is, whether it be desirable to sepa-rate the "Nautical Almanac' into two, or it may be more, sections-one circulating among astronomers, the other among mariners Private enterprise, anxions to minister to the wants of a rapidly increasing mercantile marine, has and pirated edition, valuable to sailors, but detrimental to the circulation of what may be considered the legitimate ephemeris Wouldit not be better if the Admiralty could see their way to publish an ephemens with other nautical information, entirely for the use of the marine? Such a course is followed by the Governments of other countries. The German Government publish at Berlin a compact
"Nautisches Jahrbuch," admirably adapted for naval
purposes This example is followed in Austria and in America, and we believe that the sale of our "Almanac" to the naval men of those countries has fallen oif in the last years, or at least has not kept pace with the increase of foreign tonnage

Such questions are of importance, as concerning not only the financial position of the work, but its influence There are, however, others touching the scientific and purely astronomical side of the compilation Such, for instance, is the vered question of the introduction of empirical terms in the final positions of the moon. Astronomical purists will maintain that the position of the moon should be that assigned by a purely gravitational theory, to facilitate the comparison of that theory with observation. Others demand that the place of the moon should coincide as accurately as possible, with observation, and looking at the large portion of the "Nautical Almanac" devoted to "lunar distances," it would seem (if this section is ever used) that it is desirable that the distances given should represent observed facts After a naval man has been at the trouble of observing and reducing a lunar distance, to ask him to apply a correction for the error of moon's place seems wanton and irritating And if the amount of the empirical correction is clearly ascertainable, it can be easily removed before instituting a comparison between observation and that theory from which the moon's place has been computed. But to satisfy the demands of both classes of astronomers will try the tact and ability of the new Superintendent to the utmost

The section devoted to the apparent places of the stars has also been submitted to considerable criticism. No doubt here enlargement is needed, and possibly im-proved places of the stars, particularly of circumpolar stars in the southern hemisphere, are much wanted But on this point the new Superintendent is himself a weighty authority. He has worked much and successfully in the determination and removal of systematic differences from star catalogues, and their reduction to known and recognized standards. So that, under his influence, we may hope that this section will take and maintain a foremost position

Mr. Downing has undertaken a very important duty, of great national importance, at a very critical period. We fully believe that he will grapple with this task successfully, and that, in his efforts to improve our ephemeris, he will have the assistance and support of all classes of astronomers

recommendation of the orbitalmic section of the British recommendation or me opininaling sectors of that all candidates for masters' or maters' certificates shall pass a test examination as to their ability to distinguish the a test examination as to their ability to distinguish the following colours, which enter largely into combination of signals by day or night used at sea; viz. black, white, red, green, yellow, and blue"; and they state that "the Board have been led to this decision because of the serious consequences which might arise from an officer of any vessel being unable to distinguish the colour of the lights and flags which are carried by vessels."

So far so good. But there the matter stopped officer failing to pass in colours is not deterred from going to sea : his certificate is simply endorsed " failed to pass in colours," and then it is optional with the owners, if they know of a man's colour imperfectness, to engage him or not In the majority of cases they do not know Wishing to obtain accurate information as to the views of the Liverpool shipowners upon this subject, I submitted to

them the following queries -

(1) Do you consider a colour-blind officer, mate, or captain, competent to have command of a vessel, steam or sailing?

(2) Would you consider a colour-blind man fit to be a look-out man?

In reply, 110 firms answered both questions in the negative, while one answered both in the affirmative Six said "Yes," to the first query, and "No," to the second

Six expressed the opinion that no colour-blind officer should have command of a vessel; but that colouiblindness was not a barrier to a seaman officiating as look-out

The language of the firms that answered both questions in the negative was such as to show that there was not the slightest hesitancy in the minds of the writers as to the utter undesirability, not to say danger, of employing a colour-blind man in any capacity in which he was responsible, in part or whole, for the safe navigation of the vessel

Such expressions as "emphatically no," "absolutely unfit," "not fit to serve on a ship," "very unsuitable," &c , show in unmistakable terms the views held by Liverpool

shipowners on the subject

Liverpool shipowners certainly seem alive to the dangers of colour-blind employer vate examination would seem to be coming into common practice among first class firms But the Board of Trade have still to realize that look out men, as well as officers, should not suffer from colour-blindness If shipowners themselves deem it necessary for their own interests, and the safety of the noyageurs and property intrusted to their care, to debar colour-blind seamen from their service, it is surely incumbent upon the Board of Trade, in the interests of the travelling community over whose welfare they are supposed to preside, to make perfect colour-vision a causa sine qua non that shall apply to all seamen of our mercantile marine It is but fair, however, to that complex and overburdened instrument of government to add that they have introduced a so-called voluntary test, whereby a seaman, on payment of a fee of 1s, may be tested as to the perfectness of his vision for colour Such a test must, from the very necessities of the case, be absolutely worthless What AB would be likely, had he the slightest suspicion of his colour-blindness, to seek that confirmatory evidence which would debar him from following his calling? Sailors may be person from from onewing his calling? Sailors may be pardoned if they prefer to remain in a state of blissful ignorance as to their colour vision, since they have nothing to gain, and possibly everything to lose, by undergoing an examination in colours. It must be admitted, however, that there are not wanting those who aver most positively that colour-blindness is not responsible for maritime disaster of any description whatever

Rear-Admiral P. H. Colomb is of this opinion. In discussing the action of the Washington International Maritime Conference relative to colour-blindness, he stated, "I never knew myself a case of collision where colour-blindness was in question. The statements were generally perfectly clear that wrong helm was given deliberately in the face of the colour seen, and as no authoritative teaching had existed to show that it mattered what colour was seen as long as danger was denoted, I have never been able to lay stress on the colour-blind question"

Again, Admiral Colomb expressed the opinion "that collisions at night occurred through the helm being ported to the green light, and starboarded to the red light"

Undoubtedly this is a fertile source of disaster, but seamen, unless we assume them wilfully negligent, or astoundingly nervous, could hardly fail to act correctly at the critical moment in so many instances, if there were not some other factor at work which brought them to grief I admit the truth of Admiral Colomb's statement as to collisions at night occurring through the helm being ported to the green light, and starboarded to the red But I would go further, and inquire why such a wrongful procedure should be adopted in so many cases I cannot believe it is done wilfully with the intent of causing collision, I cannot accept nervousness on the part of men, many of whom have spent a lifetime at sea, as the sole, or even a likely cause I believe that in many cases the reason why the helm is ported to the green light and starboarded to the red light is that the persons responsible for the porting and starboarding are visually incapable of differentiating between one colour and the other

Admiral Colomb's cause is undoubtedly the immediate means of effecting the collision, but that cause traced to its original source will, in the majority of cases, show neither negligence nor nervousness, but will stand revealed as the inevitable resultant of evesight that cannot distinguish red from green. Pronouncements such as those quoted above, coming from those in high places, and pregnant with the weight of authority that usually attaches to such utterances, are mainly responsible for the general layity and half-heartedness which are so characteristic of the Board of Trade's officials in respect to colour-blindness A perusal of the records of inquiries into collisions at sea, or of the courts which settle questions of maritime and commercial law arising therefrom, reveals an assounding amount of conflictory evidence as to the relative positions of the colliding vessels as judged by their side-lights. It would be more charitable to suppose that the witnesses examined were colour blind, rather than guilty of wilful and deliberate perjury In such cases the question of a look-out's colour percipience is never discussed. An examination of the witness on the spot, as to his capability of discriminating between the port and starboard lights of a ship, would set at rest the question of his physical competence to assist in elucidating the problems under considera-

The Dutch Government has long been alive to the dangers accruing from induced colour-blindness-I use the term induced in contradistinction to congenital-and adopt the most drastic measures to prevent a colourblind officer from holding a position in their mercantile marine. Among other qualifications necessary to procure a warrant empowering a man to act as mate in the merchant marine, the royal order requires —

"Colour perception perfect for transmitted light in one eye, and at least one half in the other, according to Donders's method "

Also that " the report and declaration of the expert, as required in the above, shall be considered valid for one month only from the time the test is made."

In Holland the tests are made by experts In England they are applied by persons who, however well they may be qualified to examine candidates in navigation and seamanship, have certainly no locus stands in the matter of reporting upon the perfectness, or otherwise, of

a man's visual organs.

The tests themselves that these navigation examiners The tests themselves that these navigation examiners have to apply are far from being perfect. They are established upon a wrong principle. Candidates are made to name colours, and according to the Parlamentary Report of 1887, "the only reasons for which they are reported as having failed are mability to distinguish red from green, and either, from black by daylight, and red from green and either from ground glass by artificial light,

Candidates are first required to give correct colour names to a series of eight cards coloured black, red, green, pink, drab, blue, white, and yellow, respectively A candidate is passed, however, if he names correctly

the first three

The second test consists in naming the colours of glasses some eleven in number, viz ground glass, standard red, pink, three shades of green, yellow, neutral tint, two shades of blue, and white The candidate need, howtwo shades of blue, and white ever, only name the ground glass, the standard red, and the standard green

Clearly, with such tests as these, the colour-blind may

easily escape detection. The Board of Trade return relative to colour tests for the year ending May 31, 1891, shows that out of 4688 can-didates who presented themselves for masters' and mates' certificates, 31 were rejected on account of deficient That these should be rejected after serving colour sense. colour sense. I not these should be rejected after setting an apprenticeship to the sea, is manifestly unfair. The test should be applied at the commencement of their rest should be applied at the confinemental of their natural career, and not when the initial stage is passed. Four of the 31 were reported as passing on subsequently undergoing examination, although medical expert opinion is emphatic in stating that colour-blind-ness is absolutely justime 46. Perhaps it may be that the examiners were disposed, by their leniency in passing young men whose previous "failure in colours" proved young men whose previous "failure in colours" proved them colour-blind, to atone in some slight form for the bad system which allows lads to spend the best years of their life in mastering the irksome details of a profession. before it informs them that they are visually unfitted for It is to be hoped that the investigation into the whole system of colour-testing at present being conducted by a committee appointed by the Royal Society, may lead to thorough and effective reforms T H BICKERTON

ON VAN DER WAALS'S IREATMENT OF LAPLACE'S PRESSURE IN THE VIRIAL EQUATION A LETTER TO PROF TAIT

MY DEAR PROF. TAIT,-I gather from your letter VI of September 28 (NAIURE, October 8, p. 546) that you admit the correctness of Van der Waals's deduction from the virial equation (i) when the particles are infinitely small, in which case

$$\left(p + \frac{a}{v^2}\right) v = \frac{1}{3} 2m V^2 \quad . \tag{1}$$

a representing a cohesive force, whose range is great in comparison with molecular distances; and (2) when, in the absence of a cohesive force, the volume of the particles is small in comparison with the total volume v_i , in which case the virial of the repulsive forces at impact gives

$$p(v - \delta) = \frac{1}{3} \Sigma m V^2 \qquad . \qquad . \qquad (2)$$

For hard spherical masses, the value of b is four timethe total volume of the sphere. But you ask, " How can

the actor (v - b)/v, which Van der Waals introduces on the eft (in the first case) in consequence of the finite the entire that it is the limit case, in consequence of the limit diffin eters of the particles, be justifiably applied to the term in K (or a/ν^2) as well as to that in ρ ?

In my first letter I desired to avoid the complication entailed by the consideration of the finite size of the particles, but it appears to me that the argument there given (after Van der Waals) suffices to answer your question For, if the cohesive force be of the character supposed, it exercises no influence upon any particle in the interior, and is completely accounted for by the addi-In so far, therefore, as (2) is correct tion to p of a/v" when there is no cohesive force, the effect of such is properly represented by

$$\left(p + \frac{a}{v^2}\right)(v - b) = \frac{1}{2}2mV^2$$
 (3)

in which δ is to be multiplied by a/v^2 , as well as by δ . Yours very truly.

Cutober 13 RAYLEIGH

NOTES

At the Royal College of Physicians, on Monday, when the Harveian Oration was delivered by Dr W II Dickinson, the Baly Medal was given to Prof Michael Foster for distinction in physiology, the Morgan Medal to Sir Alfred Garrod for distinetion in clinical medicine.

DR DICKINSON, in the Harveian Oration, presented an admirably clear and vigorous account of liarvey's great discovery, and of the scientific results to which it has led The earliest and most important of these results was the completion of Harvey's work by the discovery of the capillary system by Malpiglii, who was born in the year in which Harvey published his famous treatise "Harvey," said Dr. Dickinson, "had never seen a capillary, nor did the state of the microscope in his time allow of it. He was fain to conclude that the blood passed from the arteries to the veins partly by anastomoses but mainly by percolation, as water, to quote his own illustration, percolates the earth and produces springs and tivulets. Had it been possible, we may imagine the delight with which he would have witnessed the completion by vessels of his circular route" Dr Dickinson also referred, among other results of Harvey's discovery, to embolism, and to our knowledge of inflammation, or at least as much of it as concerns the capillaries. In conclusion, he said -"Knowledge has been advancing since Harvey's time in many and independent lines, the achievements of Bell, Bright, and Addison had no direct connection with his, but it is not too much to assert that the medicine of to day is scarcely less permeated with the results of Harvey's discovery than is the human body with the circulation he discovered. It does not make him small to say that what he found out must have come to light had he never lived If Columbus had not discovered America some one else must have done so before now. The law of gravity might even have been revealed in the fulness of time to another if not to Newton But the discoverer is before his time, in this lies one measure of his praise, another, and a more important one, is in the results of his discovery."

THE Electrical Exhibition, to be opened at the Crystal Palace on January 1 next, promises to be one of great interest and importance The requests for space-which already exceed a total of 200-include electric lighting plants for country and towa houses, for mines, for steamships, for railway trains, and eyen for private carriages. There are also included the newest forms of motors, generators, accumulators, and other machinery employed for producing and storing electricity. Several of the more important exhibits at the Frankfort Exhibition will be transferred to the Crystal Palace. The apparatus section will include a complete set of Sir William Thomson's stanlard electric instruments, new electro-medical and electro-thermon apparatus, the latest improvements in telephony and telegraphy, and also the most recent electrical appliances for war purposes, blasting, signalling, &c Special buildings are n.w in course of execution for bollers and other heavy machinerr.

THE Municipality of Genoa has voted the sum of 15,000 lire in aid of the International Botanical Congress which is to be held in that city in September 1892 to celebrate the fourth centenary of the discovery of America.

THE French Association for the Advancement of Science will meet at Pesançon in 1893

THE Russian Geographical Socie'y has awarded its great Constautine Medal to Prof Sludsky for his researches into the figure of the earth and his geodetical work generally. Another Constantine Medal has been given to Prof Pontebnya for his researches into the ethnography and the languages of the Great Russians, the Little Russians, and other Slavonians. Ilis two works on the Russian grammar far surpass all previous works of the kind, not only in the number of examples but in the novelty and importance of his conclusions as to the structure of the Russian and other Slavonian languages, while his works on Great and Little Russian folk lore are full of new and profound observations The Count Lutke's medal has been awarded to 5 D Rylke for an elaborate work on the determinations of longitudes in Russia by means of the telegraph, the probable error of the chief determinations does not exceed 0.016 of a second of time Another work of the same geodesist deals with the possible errors of levellings, as dependent upon temperature , they appear considerably to exceed these admitted in the best We also learn from Mr Rylke's retreatises on this subject searches that the level of the Baltic Sea, as deduced from long series of observations, regularly sinks in the direction from porth to south. Other gold medals have been awarded to Rovinsky, for a work on the geography and history of Montenegro , to M Filipoff, for researches into the changes of the level of the Caspian Sea, to M. Obrutcheff, for a geological and orographical sketch of the Transca-pian region, and to M Priklonsky, for a work on the Yakutes Some silver medals have been awarded for works, chiefly in ethnography, of minor importance

DR A R FORSYIII, FRS, and Dr. M. J. M. Hill have been nominated to fill up the vacancies caused by the retirement of Dr. Hirst, FRS, and Mr. Lachlan from the Council of the London Mathematical Society

MR JOSEPH THOMSON has returned to England from South Africa, where he has been at work on behalf of the British South Africa Company Accompanied by Mr Grant, a son of Colonel Grant, he crossed the plateau between Lake Nyassa and Lake Bangweolo, and we learn from the Times that he has been able to make suportant rectifications in the geography of the Bangweolo region. The lake, as shown in our maps, is incorrectly laid down, mainly because the one definite and precise observation taken by Livingstone has not been adhered The lake is really only a backwater of the Chambeze (the source of the Congo), which enters from the east, and issues from the west of the lake as the Luapula | The lake, in fact, hes in a very slight depression of the plateau to the north of the Chambeze Luapula Even in the rainy season Mr. Thomson believes the lake does not exceed 20 fect at its deepest. The southern shores are clothed with forests, and, as a matter of fact, Mr Thomson encamped far within the bed of the lake as it is laid down in most maps. In the rainy season the water of the lake spreads out, and covers for some distance the ground on which the forest stands.

NO. 1147, VOL. 44]

MR. W L SCLATER, the IDenuty Superintendent of the Indian Museum, Calcutta, will proceed to Upper Assam in December next, upon a collecting expedition for the benefit of the Museum From Makum he will ascend the Dibing river in boats to the mouth of the Dapha, one of its confluents from the north, and establish his camp at some convenient spot in the Dapha valley At the head of the Dapha valley rises Dapha Bum, a mountain of some 15 000 feet in altitude, on the frontiers of Chinese territory, so that there is a good prospect of the occurrence of Chinese for as in the district. The Dapha valley has been described geographically by Mr S E. Peal. who visited it in 1882 (see J A S B, lit, pt 2, p 7), but has not been much explored zoologically Mr Sclater will pay special attention to mammals and birds.

MR FRANK II BIGFLOW, who has been acting as assistant in the U S Nautual Office, has been appointed to a newly-created professorship in the American Weather Bureau. His work will relate to terrestrial magnetism and solar physics, especially in their relation to meteorology

Niws has been received of M. Paul Maury, who started in March last year fo a botanical expedition in Mexico, and of whom nothing had been heard since his departure. He appears to have made a successful exploration of the province of Huastera.

DR 5 WINGGRADSKY, of Zurich, has been appointed director of the scientific bacteriological section of the new Bacteriological Institute at St. Petersburg

A NOTICE which will be read with interest by owners of gems has been issued by Dr A Brezina, the Director of the Mineral Department of the Natural History Museum at Vienna. relates to the doings of a young man who, on September 26, contrived to conceal himself in the Department just before the time for the c'osing of the Museum He was caught, and found to be arme I with a revolver, and to have in his possession files and other implements. He had also in his possession nearly 600 gems, some of them cut, but the majority in their natural state. He has a passport, in which he is described as Hugo Kahn, of Berlin , but he has also called himself Krony, Kronek. Kornak, Kronicsalsky. His age is twenty four , he measures in height 170 cm , he is slender, has a longish, handsome face, is of a brownish complexion, has dark hair, grey eyes, and a lightbrown beard, which is of feeble growth Upon the whole, he is an attractive-looking person. He has made several journeys in Germany, France, Switzerland, and Italy, and between the middle of July last and the beginning of September he travelled through Pyrmont, Ems, Strasburg, Basel, Milan, Genoa, Nice, Monaco, Genoa, Venice, to Vienna Most of the gems (the names of which, with the exception of a rock crystal, he does not know) he professes to have bought from a barber in Marseilles. As it is important that the former owner or owners should be known, Dr Brezina prints a list of the gems, with the request that anyone who has information about them will communicate with him

ON Monday the centeary of the Royal Veternary College in ferat College Street, Camden Town, was celebrated by a lunchcon given in a tent which had been excited in front of the new buildings. The Duke of Cambridge, Preadent of the College, took the chair, and the Prince of Wales was among the general far proposing the toss, "Success and continued proingers and the control of the control of the control of the important position of the College at the present day with its humble beginnings shunderd versus."

WE regret to record the death of the Rev. Percy W. Myles, of Bright's disease, at the comparatively early age of forty-

wo, at Ealing, on October 7. He was a man of great shilly both in hierary and sclemific pursuits. He was a good botanst, and proved himself a most able editor of Nature Netes, the journal of the Schorne Society The work with which his name will be identified in the "Pronouncing "Dictionary of Schrincal Names," appended to Nicolosova" "Dictionary of Gardening", it is now recognized as a standard work by botanests. Unfortunately his professional standard work by contains. Unfortunately his professional posed to raise a "Myler Memorial Fund" on behalf of his widow; and sny contributions with the thankfully received and at once acknowledged by the Rev Prof G Henslow, Drayton House, Eding, London, W

THE Council of the Institution of Civil Engineers has susted a list of subjects on which it invites communications. The list is to be taken incerly an suggestive, not in any sense as chanavive. For approved papers, the Connecl has the power to award premiums, arrang out of voccil funds bequested for the purpose. A detailed list is given of the awards under for original communications submitted during the UMS statement.

Most than ten esthquake shocks were felt in the island of Patentlains, between Sielly and the Tanisan const, between 5 pay and the Tanisan const, between 5 pay pan and 4 a m on October 14-15. Some of the shocks were rather worken, and nearly all the mabitiants left their houses and pa-sed the night in the street or in the open country and According to intelligence received at the Central Meteorological Bareau, Rome, from Pantellaras on October 18, shocks of earth quake continued to be felt in the shall A requarkable phenomenon is announced in connection with these sewmed disturbances. A new volcann has rane from the held of the sea, not far from the coast of the Island, and has been throwing up masses of stones and rubbath to a considerable height A "slight emption" from it was referred to in a telegram sent from Rome on October 20

LAST winter there were some reports that sunset phenomena had greatly increased in brilliancy, as if something similar to the optical disturbance following the Krakatao eruption had occurred Herr Busch has remarked (Met Zeit) how difficult at is to recognize gradual variations in such phenomena, or to say where they pass beyond the normal. Even the brown-red Bishop's ring may be regarded as quite normal in winter A much more sure method of finding an optical disturbance of the atmosphere is measurement of the polarization of light. Herr Busch has earried this on systematically for some years with a Savart polariscope, and a simple instrument for measuring angles, determining the height of the two neutral points (Babinet's and Arago's) at sunset Now, the values for this height, in February and May last, considerably exceed those obtained in the three previous years, and come near those in 1886, when the last traces of the great atmost henc disturbance were still everywhere perceptible It would seem, then, that some optical disturbance has been really present, the beginning, extent, and cause of which, however, are in obscurity The desirability of systematic observations in different places is pointed out.

IN constance O'Cotober 8 (p. 549) we drew attention to three aliases insued by the Chris Signal Officer of the U.S. Army. We have now to record the publication, dated June 15 last, of an atlas containing seventy-two charts showing the normal temperature conditions in the United States and Canada by decodes, three desented to each month, for 55, are and 80 pray, Wathington words of twenty years, at had not before been able to accumulate attention of twenty years, at had not before been able to accumulate attention of the seventy of the second of the second

t years' observations, 1881-89 The charts have been carefully prepared, for the work of the Forecast Division, and will also be very useful in furnishing general information goon the average temperature of North America. The work has been prepared gunder the supervision of General Greely, although issued by the new Weather Bureau.

THE Enling Muddlesex County Times (October 17) prints the following account of an incident which occurred at "The the residence of Mr Vates Neill, Ealing, on Wednes dav. October 14 -" It appears that during Tuesday night a large branch of one of the magnificent chestnut trees standing in the ground was broken off by the force of the wind, and fell on two stripling chestnut trees near the wall. On Wednesday morning, the gardener, a man named Parker, was engaged in sawing the detached bough, Mr Delancey Neill and Mr Vertic Neill watching the operation first before noon, the first-named gentleman saw what appeared to him to be a ball of fire fall. and striking the tree in an oblique direction, alight on the ground within two or three yards of where the three were standing, whence it rebounded and exploited with a sound like dynamite Although neither of them was struck, the shock was so great that for a time all three were dazed. Mr Vertic Neill, indeed, being thrown down, and rolling over two or three times. His brother was the first to recover from the shock, and promptly went to his help, and he was removed to the house, where the feeling of dizziness spredily wore off, and beyond somewhat severe headaches, which lasted for some hours, neither of the gentlemen nor the gardener appeared to have suffered any ill effects. The trunk of the tree struck by the meteor presents the appearance of having been burned in a zigzag direction for a distance of some 20 or 30 feet

Most people who west Greece devote their attention mainly to the remains of ancient art. Dr. Philippion, of Berlin, is of opimion that they might also with advantage spend so not me in climbing the mountains of Greece. In the Assaurage development, and the abject in a capit alpage, which has been issued separately He gives an attractive account of his own experiences in climbing Mosant Cheleno, in the Peloponnece, describing admirably the impression produced upon him by the Styr. Dr. Philippion districts that the description of the produced property of the description of the described of the description of the des

MESSRS W. H ATTEN AND CO have published a second edition of the late Mr. R. A. Proctor's "Other Suns than Ours."

THE new number of the Internationality. Inchin Jin. Ethios. explain opens with most interesting paper (in Cereman by Dr. I demnarch on "The Islands of the Dead, and related Gap againsted Myth." The author shows how whilely diffused is the belief that there are far-off happy islands, where all vorts of enopyments are in store for the dead, and he suggests that Atlantis, about which so much has been written, was originally one of these inputical realine. Dr. J Jacobs concludes his critical examination (in Datch) of Dr. Plous's view of the significance of circumension.

MR 6 J SYMON, F R S, contributes to the current number of the Quarterly Journal of the Royal Meteorological Society a karned paper on the hastory of rain gauges. It was read before the Society on March 18, in connection with the annual cubbation, and is one of the curren in which hypometation, and is one of the current in which hypometation, and is one of the current which hypometation, and is one of the current which hypometation, and is one of the current current current cubbation, and is one of the current cubbation of the current cubbation of the current cubbation of the current cubbation of the current cubbation. As we have the cubbation of the current cubbation of the current cubbation of the current cubbation.

successively dealt with Among the remaining contents of the number are papers on the following subjects: meteorological photography, by A. W Clayden; on the variations of the rainfall at Cherra Poonice, in the Khasi Hills, Assam (plate). by H F. Blanford, F.R S ; some remarkable features in the winter of 1890-01 (four illustrations), hy F. J Brodie , the rainfall of February 1891, by H. S. Wallis , "South-east Frosts," with special reference to the frost of 1890-91, by the Rev F. W. Stow.

In the latest record of the proceedings of the Philosophical Society, Philadelphia, Dr Daniel G Brinton gives some vocabularies from the Musquito Coast. He obtained them from the Rev. W Siebniger, a missionary of the United Brethren. now resident in that region The most important of the vocabularies is a list of words from the language of the Ramas tribe, the only specimen of their tongue Dr Brinton has ever secured. These people live on a small island in Blomfield Isgoon There are at present about 250 of them All of them have been converted to Christianity, and, with the exception of a few very old persons, are able to speak and read English. Their native language is rapidly disappearing, and in a few years, probably. no one will use it fluently and correctly. They are large and strongly built, and are described as submissive and teachable. Their language has always been regarded as wholly different from that of the Musquito Indians, who occupy the adjacent mainland, and this is shown to be correct by the specimen sent to Dr. Brinton. It bears no relation, he says, to any other tongue along the Musquito Coast It does not, however, stand alone, constituting an independent stock, but is clearly a branch, not very remote, of a family of languages once spoken near Chiriqui lagoon, and thence across-or nearly across-to the Pacific.

THE Penang Administration Report for 1800 contains some interesting observations on the little-known aborigines of the Malay l'eminsula Observations made during the course of the year go to show that the Sakal (as distinguished from the Semang, or Pangan, as the Negrito tribes are called by the Malays of Perak and Pahang respectively) are far more numerous than was formerly supposed, and the President is of opinion that there may be more than 5000 men, women, and children in the district of Ulu Pahang alone The country on both sides of the mountain range, which forms the watershed of the Ielas, Selom, Bidor, and Kamnar rivers, is thickly inhabited by Sakat, who, although one or two large villages exist, live for the most part in groups of from two to three families. These pakar are divided into two distinct tribes, called by thomselves Sen of and Tem-be respectively, the former being the more civilized and more accessible tribe, while the latter are but little known to the Malays. Both the Tem be and Sen-or dislects, however, resemble one another so closely that it would seem to be evident that they originally sprang from the same source Words to express any numerals higher than three are not found in the dialect of either tribe.

THE mareograph in the harbour of Pola, according to Lieut. Gravel (Met. Zeitsch.), often shows, in addition to the ordinary tidal curve, certain more or less regular oscillations, generally with a period of about 15 minutes (some with one of 7 minutes) These appear to be of the nature of sesches, and to be caused by squalls, which drive water from the open sea into the partly inclosed basin of the harbour, where it rises as a wave, retires, rises again to a less height (as only part of the surplus water escapes), and so on. Thus, in the evening of July 6, 1890, after a suff west-north-west squall, there were eight pronounced oscillations, the strongest showing about 1'4 mch difference of level in 16 minutes. In another case, the harbour level rose higher than it had done for 15 years. The latter squall (a strong south-west one) affected also the Trieste mareograph, aqueous solution of azoimide was obtained upon distilling the

which showed nine wide oscillations with a mean period of r hour 46 minutes Lieut, Gratzl suggests observations as to whether sudden impulses of "bora" against the Italian coast might not heap up the water there, so that a return wave might affect the Austrian mareographs; also whether certain sudden currents which mure fishermen's nets in the Dalmatian canals may not be connected with those waves.

A CAT born with only two legs (the fore legs being absent from the shoulder-blades) has been recently described by Prof. Leon of Jassy (Nature. Rundsch) It is healthy, and goes about easily, the body in normal position. When startled, or watching anything, it raises uself to the attitude of a kangaroo. using the tail as a support. This animal has twice borne kittens; in both cases two, one of which had four feet, the other only two

WE learn from Dr Woeikof's notes of a journey in the Caucasus published in the Russian Javestia, that the Russian Ministry of Ways and Communications has issued a very interesting work on the snow-slips of the Kazbek glaciers, accompenied law an etlas of mans and plans Careful measurements of the variations in the position of the lowest end of the Devdorak glacier since 1878 have been made, and the results are given in the atlas A house has been recently built close to the clacier, and it is connected by a road (available for horses) with the villages beneath An experienced guide, who is bound to accompany the men of science and tourists who may intend to visit the glacier, stays in the house.

A KIND of artificial honey which has lately been produced seems likely to become a formidable rival of natural honey It is called "sugar honey," and consists of water, sugar, a small proportion of mineral salts, and a free acid, and the taste and smell resemble those of the genuine article Herr T. Weigle brought the subject before a recent meeting of the Bayarian Association of the Representatives of Applied Chemistry, and there is a paragraph about it in the current number of the Board of Trade Journal

RATS at Aden appear to have a vigorous appetite, and to adopt remarkable ways of gratifying it. Captain R Light, writing on the subject from Aden to the Journal of the Bombay Natural History Society, says the rats in his house-which is overrun with them-demoli-h skins, braces, whips, &c , and one night he awoke, feeling a rat gnawing at his toes. This happened in spite of a dog (a good ratter) being in the room. Captain Light was lately watching his pony being shod, and noticed the hoof apparently cut away all round the coronet, wherever it was soft. He accused the "nalband" of doing this in addition to the usual rasping of the hoof to suit the shoe. The "syce" said that the rats had done it, and that they came at night and ate away not only the pony's hoofs but those of the goat and kid, and that these animals were greatly tormented by the rats Captain Light examined the hoofs, and found be; and doubt that such was the case, the marks of the teeth being plain , moreover, he found that the horns of the kid, which had been about half an inch high, were eaten flush with the head Next morning, too, a large rat was discovered in the bedding under the horse. It had evidently been killed by a kick from hım

Two new methods of preparing azoimide, NgH, the hydride of nitrogen isolated last year by Prof. Curtius, of Kiel, have been discovered. As announced at the time in NATURE (vol. zlm p 21), Prof Curtus prepared this remarkable compound by reacting with his previously isolated hydrazine hydrate, N.H. H.O. upon hippuric acid, converting the hydrazine derivative thus obtained into its nitroso-derivative, and decomposing an alkaline solution of the latter with sulphuric acid. An

chair

of us President.

product of the latter operation. In order to obtain the free compound itself, the silver salt was prepared by allowing the distillate to flow into a solution of silver nitrate, and the precipitated silver salt, after drying, was decomposed with sulphunc acid. In a subsequent communication (comp. NATURE, vol xliii. p. 378), Prof. Curtius, in conjunction with Dr. Radenhausen. showed that the pure compound was a very volatile liquid, boiling at 37°, and of fearfully explosive properties. In the current number of the Berichte, Drs. Noelling and Grandmougin, of Mülhausen, publish a preliminary note, in which they describe a new, and from the point of view of its constitution most important, method of preparing the liquid. The phenyl ester of

azomilde is the diazobenzene imide of Griess, C₆H₅—N

just as chlorbenzene is the phenyl ester of hydrochloric acid In view of the great stability of the esters of aromatic radicles. it was hardly to be expected that diagobenzene imide would yield azoimide upon saponification But Drs Noelting and Grandmougin considered that it might be possible to obtain the latter by decomposing a nitro derivative of diazohenzene imide by means of alkalies, inasmuch as the introduction of nitro groups generally effects a considerable increase in the mobility of the acid radicle, rendering its removal by processes of saponification much less difficult. They there fore prepared the dimitro derivative of diazobenzene imide from dinitro-aniline by means of the usual diazo reaction-conversion into the perbromide, and treating with ainmonia When treated with alcoholic potash, this dinitro-diszobenzene imide readily decomposes into the potassium salt of dinitro-phenol and azoimide. Upon acidifying the product of the reaction and subjecting it to distillation, an aqueous solution of azoimide passes over, which may be converted into the anhydrous bound by the method described by Prof Curtius. The properties of the an hydrous azomide obtained by this new method agree completely with those detailed by Prof Curtius

THE second new method of preparing azomide was communicated by I'r Thiele, of Halle, at the Versammlung deutscher Naturforscher und Acrzte, held in that city in September last In the course of an investigation of the compounds

Upon treating this compound with acetic acid and zine dust, it is reduced to amido guanidine, a substance which forms wellcrystallized salts By boiling the latter with soda, decomposition ensues, with formation of free hydrazine, NoH4, which may be very conveniently prepared by this method. Upon subjecting the nitrate to the diazo reaction, the diazo nitrate of guanidine

 CN_8H_{20} and the curious constitution $\stackrel{-}{\downarrow}$ $\stackrel{\parallel}{\downarrow}$ $\stackrel{\parallel}{NH_{2}}$ NH-NThe eros unide may be obtained by distillation in a manner similar to

that described above THE additions to the Zoological Society's Gardens during the past week include a Bonnet Monkey (Macacus simicus &) from India, presented by Mr. W. Harrow, a Macaque Monkey (Macacus cynomolgus) from India, presented by Mrs. Cotton, a Common Marmoset (Hapale jacchus) from South East Brazil, presented by Mrs. Trelawny; a Gannet (Sula bassana), British, presented by Mr. J. Hitchman; a Smooth Snake (Coronella laves) from Hampshire, presented by Mr. F. C. Adams; ten Smooth Snakes (Coronella lavus), born in the Gardens.

NO. 1147, VOL. 44]

OUR ASTRONOMICAL COLUMN.

DISTRIBUTION OF LUNAR HEAT -Mr. Frank H. Very's essay on the distribution of the moon's heat and its variation with the phase, which gained the prize of the Utrecht Society of Arts and Sciences in 1890, has recently been published. bolometer in connection with a very sensitive galvanometer was used in the research, and the plan has been to project an image used in the research, and the plan has been to project an image of the moon about 3 centimeters in diameter by a concave mirror; and to measure, not the heat from the whole of this, but only that in a limited part of it, from \$\frac{1}{2}\$ to \$\frac{1}{2}\$ of the area of the disk, the observations being repeated at different points and at different phases. Measures made as thous after full moon show that the east limb was hotter than the west limb in the proportion of 92 2 to 88 9 In one observation, made a day larger. There is a regular decrement of heat in passing from higher to lower latitudes, and observations on this point appear to indicate that heat is accumulated after many days of tinuous sunshine The heat in the circumferential zone of the In this respect, therefore, the thermal image is like the visual There seems to be so ne evidence that bright regions radiate a little more than dark during the middle of the lunar day, but this is not quite proved, and with a low altitude of the sun the effect is reversed. A comparison of the curve drawn by Zollner for the moon's light with that deduced from Mr Very's observations brings out the point that visible rays form a much larger proportion of the total radiation at the full than at the partial phases, the maximum for light being much more pronounced than that for the heat. The diminution of the heat from the full to the third quarter is shown to be slower than heat from the first quarter to the full. This result agrees with that obtained at Lord Rosse's Observating, and is direct cyldence of the storage of heat by lunar rock-

GEOLOGICAL SOCIETY OF AMERICA TIII. Geological Society of America met at Washington on August 24 and 25 Owing to the death of the President, Prof Alexander Winchell, Vice-President Gilbert took the

chair

The meeting was oj ened with an address on the late President
by his brother, Prof. N. II. Winchell: Alexander Winchell
was born on December 31, 1844, in Dutchess County, N. Y.,
and died at Ann Athor on February 19 last: Ilis work was
may sided. He had studed to be a civil engineer, had a
stong leasing tow-rist theology. Il ea lato read medicine and
was, a the mathematician: He loved missic, wrote poetry, and modelled in clay and plaster. As a financial resource he became at teacher, and was very successful. He became famous by his arguments on "The little History of the Creation," and published in the Christian Advocate." Adamtes and Pre-Adamtes. an exposition of 'criptural and scientific harmony For four as a sposition of 'empirical and scientific harmony bor four years he lectured on gooding at Venderbil University. During years he lectured on gooding at Venderbil University. During wrote hany scientific strictles of a popular nature, and the agreat deal to popularize geological science. The speaker spoke eloquently of his dead brother's long and splended com-sistence of the properties of the properties of the properties of the spoke eloquently of his dead brother's long and splended com-countingly determined. Oddly complete that works the uttered in publis, were these; "When I speak to you again it will be of the inhalisman of number world." He had just infinished his weekly lecture, and referred in his closing sentence to the sub-sequent lecture that was never delivered. He discovered many new geological species, and many other geologists testified their admiration for him by naming after him species they discovered His great work for the Geological Society was touched on, and

to draft resolutions expressive of the Society's regret at the death of the President, and Steinmann, of the University of Freiburg, Germing president first paper, which consisted of the description of a geological map of South America. A large copy of the map was bung up bened the plainform, and small replicas we distributed among the sudence. Dr. Steinmann, who is a young, bezeifed, spectacled, typical German sudent, was sent to

the speaker expressed his conviction that the next generation would keenly feel the beaeficent influence of his brother's work.

At the conclusion of the memorial Prof. Edward Orton, Dr C A. White, and Mr. C. R. Van Hise were appointed a committee

602

South America by the Strasburg University some ten years ago, and spent some two years making a most thorough research in the geology of the continent, the tangible result being the remarkably complete map exhibited. His researches in South America prove that there is a most remarkable similarity South the geology of the two Americas, and especially between the geology of the southern United States and the southern continent.

logy of the southern United States and the sonthern continent. The second paper was by Dr. August Robiplets, of the University of Munich, Germany, on the Peronan, Transie, and Jurassic Formations in the East Indian Archipelago. The doctor's paper was devoted to the description of some Melozone and Paleozoto fossile ciletted in two of the Indian shands by and Paleocote fossils collected in two of the Indian islands by hils friend Dr Wichmann, during a geological exploration of the Islands Dr Wichmann being geologist of the University of Utrecht, Holland, the collections were of particular value, and Dr Rothpletz's description and classification of them, to which he devoted his paper, was thorough and minute. He took occasion to ridicule some of the classifications of fossils which put them in one category when found in one place and in another when found somewhere else.

another when found somewhere eise.
"Thermometemorphism in Igneous Rocks" was the tute of of the next paper presented. It was by M Alfrel Induce of the next paper presented in the present of the produced of the produced the present of the formation of rocks. He described the results of his researches in the lake region of England, where the volcaus forces of nature were particularly

well marked. well marked.

Prof. Alexis Pavlow of the University of Moscow, Russia, presented a paper entitled "Sur les Couches Marines terminant le Jurassique et commençant le Crétace, et sur l'Histoire de leui Faune."

Another paper, also in French, presented by Prof. Max Lohest, of the University of Liege, Belgium, was entitled "Sur l'Homme contemporain du Nammouth en Belgique." The contemporaneous existence of man was supported by proofs

Baron Gerald de Geer, of Sweden, gave an interesting account of recent changes of level along the sea board of the Scandinavian peninsula

Scandinavian peninsula

The most important new matter presented was a paper on

"Fous I Fishes of the Lower Silurian Rocks of Colorado," by

Mr C D Walcott, of the United States Geological Survey

The discovery of the fossil fish remains is of recent date, and The discovery of the fossi fish remans is of recent date, and tartest great attention among scolests and geologist from its carrying halt into the past, over a great time interval, our remains known, and appear to be the ancestral type of the great leishbyte fauns of the classic "old red sandstone" of Europe, and the Deronian group of America.

In the discussion, Profs Von Zittel, Jackel, and P. Schmidt compared the fish remains exhabited with those of the Devonian,

and stated that the Upper Silurian types were not represented an the fauna.

an the fauna.

SECOND DAY — From the committee appointed to draft appropriate resolutions relative to the death of Dr. Alexander executions are considered to the death of the draft and to continue report the place as adopted. The resolutions reported place is and too change tribute to the character of the deceased, and the draft and the this writings and lectores were attributed in a great degree the growing liberality and enlargement of thought of the more serious minded portion of the community in regard to the theory of organic evolution as presented by Darwin and his successors Dr Winchell, the report affirmed, stated and defended with Dr Winchell, the report affirmed, stated and defended with market ability and courage and personaive power this the most market ability and courage and personaive power that the most market personaive control of the personaive compatibility with one of other note fluedamental convintions or compatibility with one of other note fluedamental convintions or compatibility with one of other note fluedamental convintions or compatibility with one of other note fluedamental convintions of the personaive control of disarm hostility by showing that the evolutionary philosophy, so far from degrading and dishonouring man, makes him in a peculiar sense the head and crown of the creation?"

NÖ. 1147, VOL. 44]

In seconding the resolutions Dr. C. A. White paid a warm tribute to Dr. Winchell, with whom he had been on terms of ntimacy for many years. As a further mark of respect the resolutions were adopted by a rising rote. The first paper presented was by Dr. Frederick Schmidt, of

The first paper presented was by Dr. Frederick Schmidt, of S Petersburg, Rasia,
Prof. Gregolor Stefanesen, of the University of Bothsmest,
Roumanns, Prosented "Sur l'Existence du Dhouberfain on Roumannie," the next paper. The Professor read it is French,
illustrating it by drawings on the blackboard, and after he had
finished, Prof Dr Charles Barrois read it over again in English,
so that those who did not know French might not fole it. so that those who did not know French might not lose it. Though quite short the paper was very interesting. It briefly described a large number of bones of the Dinotherium found underly distributed over Roumania, which indusputably pointed to the existence of this almost unknown extinct animal is that to the existence of this almost unknown extinct animal in that land counties, years ago. This was probably the largest manmal and counties, years ago that the largest largest manmal as that enormous tusks, that curved downward and backward in such a way that it could only largest largest probably had a massive trunk. In character is more nearly resembled the elephant and rhinoceros of modern ages than any other known

Prof A. N Krassnof, of the Charkow University, Russia, read the next paper on the black earth of the steppes of Southern read the next paper on the black earth of the stoppes of Southern Russa, it origin, distribution, and points of resemblance with the state of the state of the state of the state of the state resemblance between the Russian steppes and the Acadeba praints to their similar origin in the layers of the vegetage of years. Their remarkable fertility was touched on generally, and a technical account of the origin of the two plans with oiven.

TECHNICAL CHEMISTRY.

IN his Cantor I ectures on Photographic Chemistry, delive e last spring before the Society of Arts, and just issued by the Society in a separate form, Prof. Meldola opens with some

Society in a separate form, Prof. Melilola opena with some remarks on the special position of technical training in chemistry, which should be catefully considered in connection with present wide-percal movement in the direction of technical process of the present wide-percal movement in the direction of technical control of the percal wide percal percal with the process of the percal wide percal p Now, in order to give technical instruction in a subject like photo-Now, in order to give technical institution in a support line purious graphy, which is so intimately connected with chemistry, we may adont one of two courses. I be student may become a practical graphy, shoch is to intimately connected with chemistry, we may adopt one of two courses. The vident may become a practical photographer in the first place, and may then be fed on to the property of the pro

analytical method may be, and has been, adopted with success, it is possible to lead an intelligent mechanic from his very day occupation to a knowledge of the higher principles of methods are not by making use of law experience of phenomena control of the principles of methods are not been as the principles of methods are not been as the principles of the control of the principles of th

general principles to start with. No person who is not grounded in such broad principles can properly appreciate the explanation of the phenomena with which his daily ex-perience brings him into contact, and if his previous traising it has difficult to enable him to understand the nature of the changes which occur in the course of his operations, be cannot derive any advantage from technical instruction. These remarks will, I hope, serve to emphasize a distinction which exists between technical chen.lsiry and other technical subjects, and I have thought it desirable to avail myself of the present oppor-tunity of calling particular attention to this point, because it is one which is generally ignored in all discussions on technical

education.

"The reason for this difference in the mode of treatment of chemical subjects is not difficult to find. The chemical tech chemical subjects is not difficult to find. The chemical tech nologist—the man who is engaged in the manufacture of useful product out of certain raw materials—is, so far as the purely identified principles are concerned, already at a very advanced chemilisty of manufacturing operations, even when there are of an apparently sumple kind, is of a very high order of complexity. There are many branches of chemical industry in which the matter of the chemical changes undergone by the materials is an authority of which the puts centre can be said to be thoroughly more for the product of the chemical industry in which the state of the chemical changes undergone by the materials is a state of the chemical chemical changes in the state of the chemical chemical changes in the state of the chemical chemical three that I am justified in stating that the chemical is chemically as well as the chemical consideration which have been offered apply to the special subject of photography with fall force. A person to the special subject of photography with full force. A person may become an adept as an operator without knowing anything may occome an adept as an operator without knowing anything of physics or chemistry, there are thousands of photographers all over the country who can manipulate a camera and develop and print pictures with admirable dexterity, who are in this position. If we adopt the narrow definition of technical instrucpostdon. If we adopt the narrow definition of rechnical instruction, we should appoint such experts in our Colleges, and through them impart the art of taking pictures to thousands of the property of the process. I work the process is the process of the process

AN ASTRONOMER'S WORK IN A MODERN OBSERVATORY

THE work of astronomical observatories has been divided into two classes, vr., satrometry and satrophysics. The first of these relates to astronomy of precision, that is to the determination of the positions of celestial objects, the second relates to the study of their physical features and chemical

Some years ago the aims and objects of these two classes of observatories might have been considered perfectly distinct, and, in fact, were so considered. But I hope to show that in more in fact, were so considered. But I hope to show that in more recent years their objects and other processes have become so intrinsed that they cannot with advantage be direded, and a fact of the state of the state

or with amounts instruments, that the writter hard superstructure of exact astronomy rests, that is to say, all that we find of information and prediction in our natificial almanaes, all that we know of the past and can predict of the future motions of the celestial bodies.

¹ Friday Evening Discourse delivered at the Royal Institution by D David Gill, F.R.S., Her Majesty's Astronomer at the Cape of Good Hop on May to , 1801.

Here is a very small and imperfect model, but it will serve to render intelligible the photograph of the actual instrument which will be subsequently projected on the screen. [Here the lecturer described the adjustments and mode of using a trainit

curcle]
We are now in a position to understand photographs of the matitiment itself. But first of all as to the house on which the death. Here, now of the vectors is the counted of the main careful and the property of the counter of the state of the s see, an admirably solid and substantial structure, innocent of any architectural chaim, and so far as it affords an excellent dwelling place, good library accommodation, and good roomsfor computers, no fault can be found with it. But these very computers, no tault can be found with it. But these very qualities render it undesirable as an observatory. An essential matter for a perfect observatory should be the possibility to equalize the internal and the external temperature. The site of an instrument should also be few. surroundings of chimneys or other origin of ascending currents of heated air. Both these conditions are incompatible with thick walls of masonry and the chimneys of attached dwelling houses, and therefore, as far as possible, I have removed the instruments to small detached houses of their own. But the transit circle still remains in the main building, for, as will be evident to you, it is no easy matter to transport such an

The two first photographs show the instrument, in one case pointed nearly horizontally to the north, the other pointed rearly vertical Neither can show all parts of the instrument, but you can see the massive stone piers, weighing many tons cach, which, resting on the solid blocks to feet below, support the pivois Here are the counter weights which remove a great part of the weight of the instrument from the pivots, leaving part of the weight of the instrument from the pivots, leaving only a residual pressure sufficient to rotable the protot preserve the motion of the instrument in its proper plane. Here are the motion of the instrument vews the moridan sty. The through which the mutument vews the moridan sty. The through which the mutument vews the moridan sty. The too the very simple, and so it it, but it requires special natural gift, patience and devotion, and a high sense of the importance of ins work to make a first rate meridant observer. Nothing apparently more monotonous can be well imagined if a man it not to the manner born.

"not to the manner born" Having directed his instrument by means of the setting circle to the required altitude, he clamps it there and waits for the slar which he is about to observe to enter the field. This is what he sees. [Artificial transit of a star by lantern]

what he sees. [Artinicial transis of a sign by lantern]
As the star enters the field it passes were after wire, and as
it passes each wire be presses the key of his chronograph and
records the instant automatically. As the star passes the
middle wire he bisects it with the horizontal web, and again similarly records on his chronograph the transit of the star over the remaining webs. Then he reads off the microscopes by which the circle is read, and also the barometer and thermometer, in order afterwards to be able to calculate accurately the effect an oater alterwards to be able to calculate accurately the Endough and an able to calculate accurately the Endough and the has observed goes on, sits after star, hour after hour, and pull after sight; and, as you see, it differs very widely from no dreamy contemplation, no watching for new stars, so consequently externing phenomena. On the contrary, there is unexpected or startling phenomena. On the contrary, there is the previously calculated circle setting for each star, allowing put sufficient unite for the new setting for the real star after the readings of the circle for the previous observation.

The previously calculated circle setting for each star, allowing on the cough of it; they have, perhaps, observed fifty or any stars, they determine certain sustrumental errors, and betake them, and contented man, At the Chey we couply two observers—one to read the circle, and one to record the instant. Four oversers are sumply, each alternove to read the circle, and one to record the instant. Four oversers are sumply, each alternove to read the circle, and one to record the instant. Four oversers are sumply, each alternove to read the circle, and one to record the instant. Four oversers are sumply, each alternove to read the circle, and one to record the instant. of atmospheric refraction on the observed altitude of the star

would find out, if he came nest morning, that the work was by no means over. By far the largest part has yet to follow An observation that requires only two of these minutes to make at night, requires at least half an hoar for its reduction by day, have to be determined and allowed for. Although solidly founded on massive plear resting on the solid rock, the constancy of the hautement's postion cannot be relied upon. It goes through small periodic changes in level, in collimation, and in aimunit, which have to be determined by proper means, and the corresponding corrections have to be computed and applied; the provides of the prov and, also, there are other corrections for retraction, dun which movive comparistion and have to be applied. But these matters would fall more properly under the head of a special lecture upon the transit instrument. I mention them now, merely to explain why so great a part of an astronomer's work comes in the dayline, and to dispel the notion that his work belongs only

One might very well occupy a special lecture in an secount of the peculiarities of what is called personal equation—that is to say, the different time which elapses for different observers say, the different time which elapses for different observers between the time when the observer believes the star to be upon the wire, and the time when the finger responds to the message which the eje has conveyed to the brain. Some observers always pires the key too soon, some always too late Some years ago of lateversed, from observations to which I will subsequently refer, that all observers press the chronograph key either too soon for bright was not too late for fraint ones.

either too soon for bright stars or too late for faint ones. Other errors may, and I am sure do, arise both at Greenwich and the Cape, from the imposs thinly of securing uniformity of The Ideal Observatory should be volid as possible as to its fundations, but light as possible as to its roof and walls—say, a light framework of time covered why canwas. But it would be undescrible to cover a valuable and permanent instrument in

this way

But here is a form of observatory which realizes all that is But here is a form of observatory which realizes all that is tequired, and which is emmently suited for permanent use. The walls are of sheet trop, when he reality acquire the tenther than the same of the same

The photograph now on the screen shows the interior of the observatory, and this brings me to the description of observations of an entirely different class. In this observatory the roof tions or an entirely different class. In this observatory the roof turns round on wheely, so that any part of the sky can be viewed from the telescope. This is so, becau e the instrument in this observatory is intended for purposes which are entirely different from those of a transit crefe. The transit circle, as we have seen, is used to determine the absolute positions of the heavesly hodies; the heliometer, to determine with greater precision than is possible by the abs lute method the relative positions of celesiisl objects

To explain my meaning as to absolute and relative positions. It would, for example, he a matter of very little importance if the absolute latitude of a point on the Royal Exchange or the Bank of England were one tenth of a second of arc (or 10 feet) wrong in the maps of the Ordnance Survey of England—that would constitute a small absolute error common to all the buildings on the situte a small absolute error cosimon to all the buildings on the same map of a part of the city, and common to all the adjoining maps also. Such an error, regarded as an absolute error, would evidently be of no importance if every point on the map had the same absolute error. There is no one who cut say at the present moment whether the absolute latitude of the Royal Exchange nny, even of the Royal Observatory, Greenwich—is known to 10 feet. But it would be a very serious thing indeed If the re-To the control works are expressed in the feet of the control works are expressed in the feet of the control works are expressed in the feet of the control works are feet of the control

We do not know, we probably never shall know with cer-lainty, the absolute places of even the principal stars to one-teath tainty, the assume places of even in the transport of a second of arc. But one tenth of a second of src.in, the measure of some relative position would be fatal. For example, in the measurement of the sun's parallax an error of one tenth of a second of are means an error of 1,000,000 miles, in round

numbers, in the sun's distance; and it is only when we can be quate certain of our measures of much smaller quantities than con-centum of a second of are, that we are he a position to begin serrously the determination of such a problem as that of the distances of the Seed stars. For these problems we must use differential measures—that it, measures of the relative positions of two objects. The note perfect featurement for such purposes

is the beliometer.

Lord McLaren has kindly sent from Edinburgh, for the put poses of this lecture, the parts of his heliometer which are necessary to illustrate the principles of the instrument This instrument is the same which I used on Lord Crawford's

Ins instrument is the same which I used on Lord Crawford's expedition to Mauritus in 18/4. It was also kindly lent to me by Lord Crawford for an expedition to the I-land of Ascension to observe the opposition of Mars in 18/7. In 18/9, when I went to the Cape, I acquired the instrument from Lord Crawford, and carried out certain researches with it on the distances

of the laxed stars.

In 1887, when the Admiralty provided the new heliometer for the Cape Observatory, this instrument again changed hands. It became the property of Lord McLaren I felt rather disloyal in parting with two old a friend. We had spent so many happy hours together, we had shared a good many anxested together, and two hours each other's weatherners or well. But my old rineral has fallen into good hands, and has found another sphere of work.

The principle of the instrument is as follows [The instrument was here explained]

There is now on the screen a picture of the new heliometer of the Cape Observatory, which was mounted in 1837, and has been in constant use ever since. It is an in-trument of the most refined modern construction, and is probably the fasest apparatus for refined measurement of celestial angles in the world.

[Here were explained the various parts of the instrument in relation to the model, and the actual processes of observa-tion were illustrated by the images of artificial stars projected on

and new illustrated by the images of articulas stars projected out of an attraction of a stronger work, there is no searching for objects, no contemplative watching, nothing sensational of any tind. On arranged and calculated beforehand, and the prospect that lies before him in him upth's work is imply more of less of a struggle with the difficulties which are created by the agustion of the tars image, consect by presipilities in historic difficulties which are created by the agustion of the tars are perfectly tranquil. You have the same effect in an exaggenistic way when looking across a bog on a hot day. Thus, generally, as the images are approximately, they appear to a moment of comparative tranquility to make he definitive bisection, or he may arrive at it by gradual approximations till he did that the wheating images of the two strus seems to pass a bisection has been made, the time is recorded on the chronic praph, there the scales are ponted on and printed off, and so the graph, then the scales are pointed on and printed off, and so the work goes on, varied only by reversals of the segments and of the position circle Generally, I now arrange for thirty-two such hisections, and these occupy about an hour and a half. By that time one has had about enough of it, the nerves are somewhat tired, so are the muscles of the back of the neck, and if the observer is wise, and wishes to do his best work, he goes to observer is wise, and wishes to do his best work, he goes to beed early and gets up again at two or three colon. In the morn-ted of the colon of the colon of the colon of the colon must be his regular outine night after night, whenever the weather is clear, if he is regulaged, as I have been, on a large programme of work on the parallaxes of the fixed stars, or on observations to determine the distance of the sun by observations.

of minor planets,
I will not speak now of these researches, because they are still in process of execution or of reduction. I would rather, in the first place, endeavour to complete the picture of a night's

in the heat place, endeavour to complete the picture of a magneta work in a modern observatory.

We pass on to celestial photography, where astrometry and astrophysics join hands. Here on the screen is the interior of one of the new photographic observatories, that at Paris, [Brief

one or one new photographic observatories, that at Paris, [Brief description.]

Here is the exterior of our new photographic observatory at the Cape. Here is the interior of it, and the instrument. [Brief description.]

The observer's work during the exposure is simply to direct het telescope to the required part of the sky, and them the school to the required part of the sky, and them the school helds in his had a little electrical switch with two keys; by pressing one key he can accelerate the velocity of the driving-rower by about 1 per cent;, and by pressing the other he can the field always, perfectly listected by the cross worse of his gainty letter, and the school performance of the school

panionamp of a pipe or coger is very helpful during long ex-posures. A man can go on for a watch of four or five hours very well, taking plate after plate, exposing each, it may be, forly minutes or an hour. If the might is fine, a second observer follows the first, and so the work goes on the greater part of the might. Next day be developed his plate, and gets something like [Star-cluster.]

Working just in this way, but with the more humble apparatus which you see imperfectly in the picture now on the screen, we have photographed at the Cape during the past six years the whole of the southern hemisphere from 20° of south declination to the South Pole

The plates are being measured by Prof. Kapteyn, of Groningen, and I expect that in the course of a year the whole work, containing all the stars to 9½ magnitude (between 200,000 and containing all the stars to 9g magnitude (between 200,000 and 300,000 sizes) in that region, will be ready for publication. This work is essential as a preliminary step for the execution in the southern liminsphere of the great work inaugurated by the Astrophotographic Congress at Paris in 1887, it hast details of which were settled at our meeting at Paris in 1887, it hast details of which were settled at our meeting at Paris in 287, it has the details of which were settled at our meeting at Paris in April last. What we shall do with the new apparatus, perhaps I may have the honour to describe to you some years hence, after the work has been done

We now come to an important class of astronomical work, more purely astrophysical, for the illustration of which I can no longer appeal to the Cape, because I regret to say that we are not yet provided with the means for its prosecution. I refer to the use of the spectroscope in astronomy, and especially to the latest developments of its use for the accurate measurement of the velocity of the motions of stars in the line of sight.

the velocity of the motions of stars in the line of signs. It is beyond the province of this lecture to enter into history, but it is impossible not to refer to the fact that the chief in pulse to astronomical work is this direction was given by Dr Huggins, our Chairman to night—nay, more, except for the early contributions of Fraunhofer to the subject, Dr Huggins certainly is the faiter of sidereal spectroscopy, and that not in one but in every branch of it. He has devised the means, pointed the way, and, whilst in many branches of the work he still continues to lead the way, he has of necessity left the development of other branches to other hands.

From an astronomer's point of view the most important advance that has been made in spectroscopy of recent years is the in the line of sight The method remained for fifteen or sixteen in the line of sight. The method remained for fifteen or sixteen between the condition or which it left the hands of Dr. Huggers, and certainly no progress in the accuracy Dr. Vogel at 7 Foodban. As a single step Dr. Vogel at 8 Foodban. As a single step Dr. Vogel at his nased the precision of the work from that of observations in the days of Prolemy to that of the days of Bradley-from the days of the old nights and pinnish to the days of telescopes. Therefore, takes Production observation as the best type of a modern over-time of the days of telescopes. fore I take a Possum observation as the new type or a mount spectroscopic observation for description, especially as I have recently visited Dr. Vogel at Postdam, and he has kindly given me a photograph of his spectroscope, as well as of some of the work done with it.

work done with it.

A photograph of the Poisdam spectroscope attached to the
equational is now on the screen. [Description, Insenting a small
photographic plate in the dark slide, durifulty the intercope to
the star, and keeping the image of the star continuously on the
star, and keeping the image of the star continuously on the
star it during an exposure of about an hour 3 and that I what is
obtained to development of the pleture.

If the star remained perfectly a text between the jaws of the

The older methods enablad us to measure motions at right angles to th line of night, but till the spectr, scope came we could not measure motions is the line of sight

NO. 1147, VOL. 44]

slit the spectrum would be represented by a single thread of light, and of course no lines would be visible upon such a thread; but the observer intentionally causes the star image to

thread; but the observer intentionally causes the star image to travel a little along the sit durang the time of expective, and so a spectium of sentille width is obtained. Voo-wall reasts how beautifully sharp are the faint lines in this spectium. Those who have tried to observe the spectium of Subra in the ordinary way, know that many of these fine lines cannot be leven or measured with cettainty. The reason is that on account of thregolutine in a sharpheter draftection, the image on account of veregularities in atmospheric refraction, the image of a star in the telescope is rarely tranqui, sometimes it shines brightly in the centre of the sist, sometimes barely in the allt at all, and the eye becomes puzzled and confused. But the photographic eye is not in the least disturbed, when the star image is in the allt, the plate goes on recording what it sees, and when the star is not in the slit the plate does nothing, and it is of no the star is not in the slit the plate does nothing, and it is of no consequence whatever how rapidly these alternate appearances and disappearances recur The only difference is that when the air is very steady and the star's image, therefore, always in the slt, the exposure takes less time than when the star is unsteady.

That is one reason why the Potsdam results are so accurate And there are many other reasons besides, into which I cannot And nere are many other reasons sensity, into which I cannot now ecter. What, however, it is very important to not es that, that we have here a method which is to a great extent independent of the statiospheric disturbances which it is all other departments of astronomical observation have imposed a limit to their precision. Accurate satiropeterioscopy, therefore, my le-pushed to a degree of perfection which is limited only by the optical and at our disposal and by the sensibility of our photo-potical disposal and by the sensibility of our photo-

graphic plates.

graphic plates.

And now I think we have sufficiently considered the ordinary processes of astronomical observation to illustrate the character processes of astronomical observation to illustrate the character completed by an account of his work by day, but to go into that matter in detail would certainly not be within the limits of his lecture. It is better that I should in conclusion touch upon this iccurre. It is better that I should in conclusion touch upon some recent remarkable results of these day and night labours. It is these after all that most appeal to you, it is for these that the astronomer labours, it is the prospect of them that lightens the long watches of the night and gives life to the otherwise. dead bones of mechanical routine

l et us take first some spectroscopic results To explain their meaning let me remind you for a moment of the familiar analogy between light and sound

The puch of a musical note depends on the rapidity of the

vibiations communicated to the air by the reed or string of the musical instrument that produces the note, a low note being musical instrument that produces the note, a low note being given by slow with attons and a high one by quick vibrations.

Just in the same way red light depends on relatively slow wibrations of ether, and blue or violet light on relatively quick vibrations. Well, if there is a railway train rapidly approaching one, and the engine sounds its whistle, more waves of sound from that whistle will reach the ear in a second of time than would reach the ear were the train at rest. On the other hand, if the train is travelling at the same rate array from the observer, fewer waves of sound will reach his eass in a second of time.

Therefore an observer beside the line should observe a distinct change of puch in the note of the engine whistie as the train be and has been observed.

Just in the same way, if a source of light could be moved rapidly enough towards an observer it would become bluer, or if away from him it wou'd become more red ia colour Oaly it If away from him it wou'd become more red as colour. Only it would require a change of velocity in the moving light of some control of the control of the control of the control of colour sensities to the eye. The experiment us, therefore, not hiely to be frequently shown at that lecture table?

But the spectroscope enables such changes of colour to be most appended illustration of the that central represent, vis. copies of three negatives of the spectrum of a Ausige, taken a Topishman to October and December of 1888, and in March Population.

1889. "Black line (the picture being a negative) represents the bright line Hy given by the artificial light of hydrogen, the strong white line in the picture corresponds to the black absorption line which is due to hydrogen in the atmosphere.

Why is it that the artificial hydrogen line does not correspond

with the stellar line in all these pletures? The answer is, either the size is moring towards or from the surch in the line of succession to the surch in the line of succession the surch in the line of succession the surch in the surch condition to the discussion of a Aurigez why then does not the surch line and the surch line surch in position with the terrestrial moving with respect to the engineering in the a Aurige is moving with respect to the surch with the surch line and the surch line is successive. Well, that also is clear; the stellar line is displaced towards the red end of the spectrum—surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is surch line in the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line in the surch line is successful to the surch line is successful to the surch line in the surch line is successful to the surch line is success

that is to say, the star light is redder than it should be in con-sequence of a motion of recession, this proves that the star is moving away from us, and measures of the photograph show the rate of this motion to be 15½ miles per second. We also know that in October the earth, in its motion round the san, is mov-ing towards a Aurige in raining away from the sam. Conse-seen that a Antige is raining away from the sam. quently, at that time, their relative motions are nearly in-sensible, because both are going at the same rate in the same direction, and we find accordingly in October that the positions direction, and we find accordingly in October that the positions of the stellar and artificial hydrogen lines perfectly correspond Finally, in March, the earth, in its motion round the san, is moving away from a Aunge, and as a Aunge is also running away from the sun, the star-light becomes so much redder than normal that the stellar hydrogen line is shifted completely to one side of the hydrogen and artificial line.
The accuracy of these results may be proved as follows.

If we measure all the pho'ographs of a Aurigae which Dr Vogel has obtained, we can derive from each a determination of the relative velocity of the motion of the star with respect to our

Of course these velocities are made up of the velocity of motion of a Aurigo with respect to the sun (which we may reasonably assume to be a uniform velocity) and the velocity of reasonably assume to be a uniform velocity) and the velocity of the earth due to its motion round the sam. But the velocity of the earth's motion in its orbit is known with an accuracy of about one fire-hundredth part of its amount, and therefore, within that accuracy, we can allow precisely for its effect on the relative relocity of the earth and a Aurige When we have done so we get the following results for the velocity of the motion of a Aurige with respect to the sun. You see by the following table how beautifully they agree in the Potsdam results, and how comparatively rough and unreliable are the results, and by the older method at Greenwich —

a Aurage - Potulam a Aurigic Fro

NO. 1147, VOL. 44

I believe that in a few years—at least, in a period of that that one may hope to see—we shall not be content merally that the may be the seement and the seement and the seement of the se mise the fundamental unit of astronomy, the distance of the sun from the earth.

I will take as another example one recent remarkable spectro-

scople discovery.

Miss Maury, in examining a number of photographs of stellar

spectra taken at Harvard College, discovered that in the spectrum of β Aurigor certain lines doubled themselves every two days, becoming single in the intermediate days. Accurate Potsdam observations confirmed the conclusion.

dam observations consument the conclusion.

The picture on the screen shows the spectrum of B Aurigor photographed on November 22 and 25 of la-1 year. In the first the lines are single, in the other every line is doubled. Measures and discussion of a number of these photographs have shown that life doubling if the lines it perfectly accounted for by the supposition of two suns revolving round each other in a period of four days, each moving at a velocity of about 70 miles a second in its orbit

a second in its orbit

When one star is approaching us and the o her receding, the
lines in the spectrum formed by the light of the first star will be
moved towards the blue end of the spectrum, those in the spectrum of the second star towards the red end of the spectrum trum of the second star towards the red end of the spectrum. Then, as the two stars come into the same inwe whi us, therm too those become at right angles to the line of ught, and their two spectra, not beleg affected by motion, will perfectly connected, but then, af er the stars cross, their spectra again separate in the opposite direction, and so they go on.

Thus by means of their spectra we are in a position to watch and to measure the relative motions of two objects that we can

and to measure the relative motions of two objects that we can never see apart—nay more, we can determine not only their period of revolution, but also the velocity of their motions in their orbits. Now, if we know the time that a hody takes to complete its revolution, and the velocity at which it moves, clearly we know the dimensions of its obtity and if we know the dimensions of an orbit we know what attractive force is neces dimensions of an orbit we know what attractive force is necessary to compel the body to keep in that orbit, and thus we are sary to compel the body to keep in that orbit, and thus we are two suns, which revolve about each other in four day, they are only between 7 and 8 millions of mitter (or one-tweight of our distance from the sun) apart, and if they are of equal weight they each weigh rather over double the weight of

I have little doubt that these facts do not represent a per-manent condition, but simply a stage of evolution in the life-history of the system, an earlier stage of which may have been a pebular one

Other similar double-stars have been discovered both at Potsdam and at Cambridge, U.S., stars that we shall never see separately with the eye aided by the most powerful telescope; but time does not permit the to enter into any account of them I pass now to another recent result that is of great cosmical

Il pass now to another recent result that us of great comincia. The Case photographic atta-charing of the southers hearisphore has been already referred to. Good with the photographic decremenations of these magnitude by Dr. Good with the photographic decremenations of these magnitudes, both Prof. Kaptporn and the control of the style-that a, m the Milky Way—the stars are systematically the control of the style-that a, m the Milky Way—the stars are systematically thought as the control of the style-that a, m the Milky Way—the stars are systematically thought as the control of the style-that are started. One of two things was estimated. One of two things was estimated that the expension of two the started of the started of a magnitude. One of two things was estimated that the expension of the phase that the expension of the started of Pickering, and the started of the started of Pickering and experience of the phase of Pickering as precionce of Darrobancterang were enablised on the science. It is that discussed the various types of the speace, of the be lighter states, as cased the various types of the speace, of the be lighter states, as desired to the science of the started of the start

Milky Way, whilst stars of other types are fairly divided over

the sky.

Now, it as of the Sirius type are very white it are, very rich, relative to other stars, in the rays which act most strongly on a photographic plate. Here, then, is the explanation of the results of our photographic star-charting and of the discordance between the photographic and visual magnitudes in the Milky the photographic and visual magnitudes in the Milky

The results of the Cape charting further show that it is not alone to the brighter sixrs that this discordance extends, but it extends also, though in a rather less degree, to the fainter stars of the Milky Way Therefore, we may come to the very re-markable conclusion that the Milky Way is a thing apart, and that it has been developed perhaps in a different manner, or more probably at a different and probably later epoch, from the rest of the sidereal universe

Here is another interesting cosmical revelation which we owe

Here is another interesting counts a servanous most photography to photography the beautiful contellation Orono, and many in this thearer have before seen the photograph of the nebula which is now on the screen, taken by Mr. Roberts.

Here is another photograph of the same object, taken with a much longer reposure. You see how over-copone, in fact when the property of the property of the property of the content of the property of the content of the property revealed

reveaue:
But I do not think that many persons in this room have seen
this picture, and probably very few have any idea what it represents. It is from the original negative taken by Prof Pro-tering,
with a small photographic lens of short focu, after six hours
exposure in the clear au of the Audes, to,coo feet above sea

The field embraces the three well-known stars in the belt of Orlon, on the one hand, and A Orionis (Rigel) on the other You can hardly recognize these great white patches as stars, their Ill defined character is simply the result of excessive over But mark the wonders which this long exposure with exposure a lens of high intrinsic brilliancy of image has revealed is the great nebula, of course terribly over-exposed, but note its woulderful fainter ramifications. See how the whole area is more or less nebulous, and surrounded as it were with a ring fence of nebulous matter. This nebulosity shows a special concentration about & Orionis.

Well, when Prof Pickering got this wanderful picture, know ing that I was occupied with investigations on the distances of the fixed stars, he wrote to ask whether I had made any obser vations to determine the distance of & Orionis, as it would be of great interest to know, from independent evidence, whether this very bright star was really near to us or not. It so happens that the observations were made, and their definitive reduction that the observations were made, and their dennitive reduction has shown that \$\beta\$ Orionis is really at the same distance from us as are the faint comparison stars. \$\beta\$ Orionis is, therefore, probably part and parcel of an enormous system in an advanced but incomplete state of stellar evolution, and that what we have seen

incompete state of stemar evolution, and that what we have seen in this wooderful picture is all a part of that system I should explain what I mean by an elementary or by an advanced state of stellar evolution. There is but one theory of celestial evolution which has so far survived the test of time and companison with observed facts, viz the nebular hypothesis of Laplace Laplace supposed that the sun was originally a huge gaseous or nebulous mass, of a diameter far greater than the orbit of Neptune. I say originally-do not misunderstand me orbit of Neptune. I say originally—do not misinderstand me We have finite minds, we can imagine a condition of things which might be supposed to occur at any particular instant of time however remote, and at any particular distance of space however great, and we may frame a theory beginning at another time at Il more remote, and so on. But we can never imagine a

time at II more remote, and so on. But we can never imagine a theory beginning at an infinite distance of time or at an in finitely distance point in or at an in finitely distant point in space. Thus, in any theory which may with his finite mond can devise, when we can do organized to the contract of our present system. The central part of this ball was certainly much more condensed than the rest, and the whole ball revolved. There is nothing improbable in this hypothesis. If gaseous

matter came together from different parts of space, such coalttion wou'd unquestionably occur, and as in the meeting of oppo-site streams of water or of opposite currents of wind, vortices would be created, and revolution about an axis set up, such as we are familiar with in the case of whirlpools or evelones. The resultant would be rotation of the whole globular gaseous mass

shout on ave. Now this gaseous globe begins to cool, and as it cools it reessarily contracts. Then follows a necessary result of connecessarily contracts traction, viz the rotation becomes more rapid This is a wellknown fact in dynamics, about which there is no doubt known meet in dynamics, about which there is no doubt. Thus, the cooling and the contracting go on, and, simultaneously, the velocity of totation becomes greater and greater. At last the time arrives when, for the outside particles, the velocity of rotation becomes such that the centrifugal force is greater than the attractive force, and so the outside particles break off and form Then, as the process of cooling and contraction proceeds still further, another ring is formed, and so on, till ceeds still further, another ring is formed, and so on, till we have, finally, asuccession of rings and a condensed central ball, have finally, asuccession of rings and a condensed central ball, on uniformly, or if some of the gaseous matter of the ring is more easily liquefied than other, then probably a single nucleus of liquid nutter will be formed in that ring, and this nucleus will finally, by ntraction, absorb, the whole of the matter of will many, by netraction, amount the whole of the matter of which the ring is composed—at first as a ga eous hall with a condensed nucleus, and this will finally solidify into a planet, Or, meanwhile, this yet unformed planet may repeat the lustory of its parent sur By contraction, and con equent acceleration of its rotation, it may throw off one or more rings, which in like manner condense into satellites like our moon, or those of Jupiter, Saturn, Uranus, or Neptune Such, very briefly outjapiter, Saturn, Uranus, or Neptitute Such, very briefly out-lined, is the celelizated hebular hypothesis of Laplace. No one can postively say that the hypothesis is true, still less can any-one say that it is untrue. Time does not permit me to enter ian the very strong proofs which Laplace urged in favour of its oci entence

acceptance.

But I beg you for one moment to cast your imaginations back
to a period of time long antecedent to that when our sun had
begun to disentangle itself from chaos, and when the fleecy
clouds of cosmic stuff had but commenced to rush together. What should we see in such a case, were there a true basis for the theory of Laplace? Certainly, in the first place, we should have a huge whirlpool or cyclone of cosmic gaseous stuff, the formation of rings, and the condensation of these rings into gaseous glot es.

Remembering this, look now on this wonderful photograph of the nebula in Andromeds, made by Mr Roberts. In the largest telescopes this nebula appears simply as an oval patch of nearly uniform light, with a few dark canals throught it, but no idea of its true form can be obtained, no trace can be found of idea of its true form can be constant, no trace can be found of the significant story which this photography lells. It is a picture that no human eye, unaided by photography, has ever seen. It is a true picture drawn without the intervention of the hand of fallfible man, and unufluenced by his bias or imagination. Have we not here, so at lesst it seems to me, a pacture of a very early stage in the evolution of a standbutter or sun-system—a phase in the history of another star system similar to that which once occurred in our own-millions and millions of years ago, when our earth, nay, even our sun itself, "was without form-and void," and "darkness was on the face of the deep."

During this lecture I have been able to trace but very imper-fectly the bare outlines of an astronomer's work in a modern secus sine ware outlines of an astronomer's wo.k in a modern observatory, and to give you a very few of its fatest results-results which do not come by chance, but by hard labour, and to men who have patience to face dull daily routine for the love of science—to men who realize the imperfections of their methods, and are constantly on the alert to improve them

The mills of the astronomer grind slowly, and he must be

mills of God, to grand exceeding small
I think be many well take for his motto these beautiful lines.—

" Like the star Like the star
Which shines afar,
With an hasse,
Without rest,
I et each man whiel
With steady sway.
R and the task
Which rules the day,
And do his best "

COPTIC PALÆOGRAPHY

Album de Paléographie Copte pour server à l'Introduction Paléographique des " Actes des Martyrs de l'Erybte" Par Henri Hyvernat (Paris Leroux, 1888)

N all the wide range of subjects connected with archæology, it would perhaps be difficult to find one so little studied as that the name of which stands at the head of this article It is not that it is unimportant, on the contrary, it is most important, it cannot be said to be uninteresting, for the most elementary study of the subject shows it to possess considerable attractions for the philologist, historian, and antiquary The little interest which, until the last few years, has been shown in matters relating to the Coptic language and literature is probably to be attributed to the fact that printed Contic texts are scarce, and that the comparatively few manuscripts which exist are scattered throughout the libraries of Europe.

It will be remembered that in the year 188; M. Hyvernat began to publish the martyrdoms of famous Coptic saints, with a translation in French entitled "Les Actes des Martyrs de l'Égypte"; the Coptic texts were edited chiefly from manuscripts in the Vatican and Borgian Libraries Considerable interest was aroused by his work, and it was hoped that scholars would soon possess accurate copies of the texts of the martyrdoms which form so large a section of the rich collections of Coptic manuscripts at Rome. It may be arrued that the parratives of the sufferings and deaths of Coptic martyrs have much in common, and that a few examples of this class of literature would have been sufficient, but it must be remembered that the historical allusions and incidental remarks. made in them give them a value far beyond their importance as religious documents; while the uncommon words, and unusual forms of the Greek words which their writers borrowed, enrich the Coptic lexicon, and afford material for the student of hieroglyphics who makes a comparative study of the dialects spoken by the Copts and by their ancestors the subjects of the Pharaohs The first volume of the work, in four fasciculi, has appeared, and it is hoped that the second volume, which is promised to contain a critical introduction, &c , will not be long delayed

Meanwhile, however, M. Hyvernat has given us his "Palæographic Album," and it is to this important publication that we must now give our attention; the scientific plan which he has followed in setting before scholars facts and nothing but facts, and his systematic arrangement of them, make his work most welcome The first Coptic scholar who gave his attention to the subject of Coptic palæography was Zoega, the Dane, and in his famous "Catalogus Codicum Copticorum," published (after his death) at Rome in 1810, are given seven plates containing specimens of the writing found in Coptic manuscripts of various periods; since that time facsimile specimens of important manuscripts have been published, as, for example, a page of the famous Gnostic work, "Pistis Sophia," in the "Facsimiles of Ancient Manuscripts, &c.," issued by the Palæographical Society (Oriental Series, plate 42, 1878).

The work before us contains fifty-seven large folio plates, upon which are reproduced by photography about one hundred examples of Contic writing: the execution of these plates is perfect, and M. Hyvernat has shown great knowledge and judgment in making the selection The original manuscripts are preserved in Rome, Milan, Turin, Naples, Paris, London, and Oxford, and the time and labour spent by him in reading and examining them must have been very considerable. The manuscriptsthat is, books made of parchment and paper, for M Hyvernat excludes inscriptions upon stones, and papyri, whether contracts or otherwise-belong to all periods; the earliest cannot be later than the sixth century A D . and the latest dates from the last century We have thus for palæographical investigation a field of not less than twelve hundred years

The specimens of the writings anterior to the ninth century have been taken from manuscripts which are, by the common consent of the best authorities, admitted to belong to this period, all those after the ninth century are taken from dated manuscripts, and thus there is no doubt possible as to their age. The wisdom of this plan is evident, for, in the case of uncial writing, the character of which practically remained unchanged among the Copts for centuries, it is almost impossible to assign an exact date to a manuscript unless a dated standard is forthcoming Coptic manuscripts which are to be attributed to the sixth or seventh century are rare, and as examples of them M. Hyvernat has selected the Gnostic treatise called "Pistis Sophia"1 (Brit. Mus , No 5114) and the life of St Pachomius, 2 the pages are small quarto in size, with two columns of writing to the page, and ornamentation is rare. In the seventh and eighth centuries the writing becomes firmer and bolder, the pages are larger, and the sides of the columns are ornamented with graceful designs and birds (doves?). The picture of Job and his three daughters (PI 5), wearing Byzantine costumes and ornaments, is very instructive Pl 6 gives a leaf from a palimpsest manuscript, inscribed in Coptic with verses from the Old Testament, and in Syriac with the martyrdom of St Peter of Alexandiia

Of the tenth and eleventh centuries we have fine specimens of manuscripts containing homilies, canons, sermons, martyrdoms, &c , the pages are large, the writing, in two columns, is bold and handsome, the initial letters of paragraphs are large, and stand away from the columns, which are often profusely decorated with birds, flowers, ornaments in the shape of vases, &c last pages of works of this period often contain portraits of those who are referred to in them, and the larger manuscripts have full-page illustrations of the subjectmaiter; as, for example, Theodore the General overthrowing the dragon and rescuing the widow's children (Pl 16), St Mercurius destroying Julian the Apostate (Pl 17), and "Moses the Prophet" standing with bare feet by the side of the burning bush (Pl. 19). On Pls 14, 21, and 32 are some interesting examples of Coptic cryptography and cursive writing. At the end of the tenth century the first page of each work in a manuscript is ornamented with deep borders of tracery and interlacing

The test, with Latin translation, was published by Schwarze at Berlin in 1851

The text, with French translation, was published by Amélineau, "His tours de Saint Pakhlime" (Paris, 1880) in various colours, and the initial letters are very large (Pls. 34, 38)

A fine example of the writing and illumination of the thirteenth century is that given on Pl. I, from a Coptic and Arabic Evangelarium written A.D 1250, in it St. Mark, seated, is about to receive in a napkin the book of the Gospels from St. Peter, and by his side is a stand in the shape of that used to hold a Koran : opposite is a scene in which John the Baptist is baptizing Christ in the lordan, in the presence of two angels, who hold napkins, and above them is descending from blue heavens the Holy Ghost in the form of a dove Behind John the Baptist is a tree, in the trunk of which an axe has been struck. Of illustrated Gospels of this period we have excellent specimens on Pls 44-47, where the Transfiguration, the devils entering the swine, the Marriage at Cana, the Last Supper, the Crucifixion, &c, display a quaint mixture of ancient Coptic, Byzantine, and Arab methods of illumination and ornamentation. Of manuscripts of the thirteenth and fourteenth centuries good examples are given on Pls. 50 foll, with facsimiles of the elaborate crosses of the period and of the portraits of the four Evangelists in circles. The space at our disposal will not allow a more detailed description of the contents of the "Album de Palcographie Copte" than that given above, which will serve to indicate the great value of the work to scholars

The Copts, or "Egyptian" Christians, played no unimportant part in the history of Egypt after the preaching of St Mark at Alexandria, AD 64, and from that time until the present day they have steadily and consistently maintained their religious opinions without change. They clung fast to their language, in spite of the widespread use of Greek in Egypt in the earlier centuries of this era , and although they adopted the Greek alphabet, with the addition of some few signs from the demotic, and borrowed largely from the Greek vocabulary, they did not cease to write their books in Coptic nor to celebrate the services of their Church in that language After the conquest of Egypt by the Arabs, the Copts held positions of dignity and importance there for some hundreds of years, but about the twelfth century they seem to have fallen into poverty and contempt, and about a century later it seems that they ceased to produce literary works; moreover, the growing custom of adding Arabic translations by the side of the Copuc texts proves that the knowledge of Coptic was dying out. During the next few centuries it probably became the study of the learned. In the course of the last two centuries, travellers in the East have brought to Europe numbers of Coptic manuscripts, and among those deserving special mention are Pietro della Valle, and Huntingdon, Assemani, Curzon and Tattam. The revival of Copiic learning was begun by Abela, a Makese, and his work was carried on by kircher, Petræus, Jablonski, Renaudot, Wilkins, Vansleb, Lacroze, Tuki, George, Zoega, Quatremère, Tattam, and Peyron, among those who have done much excellent work in Coptic during the present century are Schwartze, Lagarde, Revillout, and Ruckert. The recent works of Amélineau and Hyvernat show that serious attention is now being paid to the Coptic language for philological and ecclesiastical purposes, and that the publication of new material is going on rapidly

In conclusion, all lovers of Copius hterature one a debt of gratude to M. Henri Hignard, formerly President of the Academie de Lyon, for his hiberality in undertaking the expense of publishing this work, and to M Hyvernat for the excellent way in which he has made use of the funds so generously placed at his disposal

BRITISH MUSEUM (NATURAL HISTORY) CATALOGUES.

Systematic List of the Frederick E. Edwards Collection of Britath Ologeone and Excess Molluca in the British Museum (Natural History), with Reference to the Type Speamens from similar Horizons contained in other Collections belonging to the Geological Department of the Museum By Richard Bullen Newton, FG S Pp. xviii and 563, with a large Folding Table (London Printed by order of the Trustees Soid by Longmans and Co; Quartich; Dulau and Co; Kegan Paul, Trench, Trubner, and Co, and at the Natural History Museum 1891)

THE interest which attaches to the records of past periods of our earth's history is greatly enhanced when we find them in the strata forming the very ground beneath our feet. Such is the explanation of the origin of the well-known Edwards Collection of Eocene Mollusca, which forms the subject of the volume before us. Mr Frederick Edwards resided at Hampstead some fifty years ago, at a time when the Primrose Hill tunnel of the London and North-Western Railway was formed. and the Archway Road, Highgate, had lately been cut. and, later still, the Great Northern tunnel under Copenhagen Fields These, and many brick-field excavations in the north of London, led to the discovery of abundant fossil-remains around his residence, and attracted the attention not only of Mr. Edwards, but of Dr Bowerbank. Mr Wetherell, Prof. John Morris, Mr Searles V. Wood and his son, Mr Sowerby, Mr. White, Mr Page, and other geologists living in Highbury, Highgate, Hampstead, and Kentish Town, who formed among themselves a small Naturalists' Society, known as the "London Clay Club," the members of which met periodically at each other's houses, to compare and exchange specimens. and to name the fossils they had discovered in the London clay Mr Wetherell, Dr Bowerbank, and Mr. Frederick Edwards made most extensive collections; but, whilst Wetherell and Bowerbank collected from the London Clay, the Chalk, and other formations, Mr. Frederick Edwards devoted all his attention to the Mollusca of the London Clay and other Tertiary beds of the south-east of England. All his summer holidays were spent in such spots as the New Forest (where, at Brockenhurst, Bramshaw, Lyndhurst, and many other spots, assisted by Mr. Henry Keeping, he opened numerous trial-pits), or at Barton and Hordwell on the coast of Hampshire, Colwell Bay, Headon Hill, Osborne, Hempsted, Bembridge in the Isle of Wight, and Bracklesham Bay, Sussex. He collected at all these places, and carefully recorded the localities from whence his specimens were derived. With infinite care he mounted and named these delicate Tertiary shells, and the beautiful specimens. so prepared have been preserved in their entirety in the National Museum.

After the formation of the Palzeontographical Society, a large number of Mr. Edwards's Mollusca were monographed by him from 1849 to 1850 (five parts), and continued by S. V. Wood, 1851 to 1879, (four parts) appears were published in the London Geological Journal, the Geological Society of London University of the Geological Society of London University of London 1840 (London 1840).

The unpublished labour which Mr. Edwards expended on his cabinets greatly exceeded that which he devoted to the publication of a part of their contents, as may readily be seen by a study of his collection; and when it is known that this work was all performed in the lessure hours of a busylife as a Master-in-Chancery, hearing and deciding law cases in Chambers all day, one is astonished to find how much he was able to accomplish.

The collection contains no fewer than 39,191 specimens, referred to 1805 species of Mollusca, divided into the following classes:—

Of this number 585 are manuscript species, proposed by F. E. Edwards, which have not yet been described, so that nearly one-third has to be deducted from the above total if we would arrive at the actual number of species already figured and described.

It may be objected that these manuscript names ought not to have been printed, but Mr. Newton points out, in the preface to bus catalogue, that these have got into circulation abroad in hists published by German and French palesontologists, with whom Mr. Edwards had corresponded, until, hise some paper-currences, hey have obtained for themselves an artificial value, and it would be inconvenient to omit to mention them in a list of Mr. Edward's own collection. Mr. Newton, moreover, promises shortly to describe and figure them, thus giving them their full **ginate-value**, a promise which we sincerely trust he will find lesiure to perform.

In addition to the specimens in F. E. Edwards's own collection, figured and described by himself and others, all those in the Brander, Sowerby, Dison, Bowerbank, and Wetherell collections are duly recorded; so that much valuable information as to the whereabouts of these types, and references to the works in which they are recorded, has been carefully brought together in this volume by Mr Newton.

Apart from the vast variety, as well as the rare beauty of form, by which the Mollusco of the Eocene period at once arrest the attention of even the most unlearned, to the student of palezontology they afford unmustabable evidence of the existence in this sarliest Tertiary period of subtropical marine conditions over this portion of the earth's surface, which now forms South-eastern England. Several extinct forms of Nautilus and Cuttlefishes, associated with huge species of Certifising. Cowries, Cones, Voluces, and such genera as Rottellaria, Mitray, Cones, Voluces, and such genera as Rottellaria, Mitray, Margiulala, Cancellaria, Oliva, Ouula, and Srephi,

with Terebra, Pirinia, Phorus, Solarium, Nersta, and Chaton, make up a rich display of Mollusca belonging to the warmer seas of the globe, and if we add such genera as Pholadomya, Spondylus, Crassatella, and many of the other bivalves, they tell the same tale Crustacea, Echinodermata, and Corals were also present, together with numerous Turtles, whilst along the shores of the rivers huge Crocodiles patiently awaited the Palantheria and Anoblotheria from the neighbouring lands. Terrestrial vegetation, washed down from the Eocene continent, also proves to be of a tropical kind -- Palms, Cacti, Dryandra, Maple, Azalea, Acacias, with others, belonging to more temperate latitudes, forming a part of the vegetation of our island to day. Nor were the terrestrial Mollusca unaffected by the increased temperature, for we find large Bulimi and Helices unlike those now living in this country, whilst the species of Ismnea and Planorbis were both large and very abundant, and were associated with Potamides, Mclama, and other exotic genera in its streams. That there must have been at that time a close connection between our English Eocene area and the much larger Eocene area of France, cannot be doubted, for the beds of the l'aris basin and those of Hampshire and London are capable of close correlation, and many genera and species are common to both areas.

Mr. Newton has fortunately obtained the co-operation of Mr. George F. Harris, who has, in an appendix added some valuable tables, showing the probable equivalent horizons of our several English Tertiary beds with those on the Continent, in France, lielgium, and Germany, and as far east a Austria and Italy, and southwards to Spain. These tables will prove of the greatest value to the student who seeks to understand, and even to map out, the former geographical extent of the several successive Territary deposits of Europe, with their varied land, freshwater, and marine records of past life, both animal and vegetable

Most of the points dealt with by Mr Newton in the introduction to his list have reference to questions of priority in names, and explanatory notes in justification of some which have been abolished-either because the name had been pre-occupied for a genus of fishes, or buds, or reptiles, &c., or because it had been discovered that another author had previously described the same shell, and had at an earlier date given it another name Many old favourites have thus been relegated to obscurity, whilst fresh names, dug up from some forgotten corner. have, by the law of priority, taken their places. Thus -Meretrix, Lamarck, 1799, takes the place of his better known Cytherea of 1806, the latter having been applied by Fabricius, in 1805, to a dipterous insect. Triton, De Montfort, 1810, gives place to Lampusia, Schumacher, 1817, "having been applied by Linnæus to a Cirripede in 1767." But as no genus of Cirripedes is known by that name at present, this is a needless and undesirable alteration, especially as Mr. Newton remarks, "the genus Traton still continues a favourite name among conchologists"; we would add, "long may it continue" so Darwin says: "I cannot doubt that the Trilon described by Linnæus was only the exuvia of some Ralames (probably B. portatus), Linnæus mistaking the proboscidiformed penis for the mouth of his imagined

distinct animal" (Darwin's Balani la, Ray Soc., 1854, p. 158)

It would be an immense gain if every name proposed to be altered had to pass through a regularly-constituted committee of investigation before it was accepted and allowed to pass current. As it is, endless confusion must arise, and needless alterations will for ever be made, serving no good end to science.

Mr R B Newon's systematic list of the Eocean and Oligocean Molliusca of our British strata will prove extremely valuable to all those who take an interest in our Tertiary deposits and their contained organisms. Every curator of a paleontological collection must have it, as a work of reference, by his side, as, for this section of fossils, it takes the place of "Morris's Catalogue," now long out of date We shall be very glad to see other sections treated in a similar manner—indeed, Messrs -A. Smith Woodward and C D. Sherborm have already catalogued the fossil Vertebrata of the British Isles in 1890, and the work has been published by Dulau and Co.

THE LIFE AND WORK OF A NORFOLK GLOLOGIST.

Memorials of John Gunn being some Account of the Cromer Forest Bed and its Fossi Mammalia Edited by H B Woodward and E T Newton Pp xi, 120; 13 Plates (Portrait and Fossil Mammalia) (Norwich: W A Nudd, 1861)

ALL students of the geology of the eastern and central parts of Norfolk and Suffolk will welcome this book, as giving the well-matured opinions of a geologist whose life work was chiefly concerned with the Forest Bed and its associated formations, Crag and Drift Those too who knew Mr Gunn must be glad to have this memorial of so courteous, kindly, truth-seeking a man. No one enjoyed his friendship but was the better for it, and the writer looks back on days spent in his company, both in the field and at meetings of the Norwich Geological Society, as amongst the happiest events of a long sojourn in the Eastern Counties. Until reading this book he did not know the politics of Mr. (runn, and he is glad to find another of many instances in which such matters are kept in the background, as regards scientific intercourse and personal friendship.

To those who, like the writer, are not greatly enamoured with biography and its multiplicity of personal details it is satisfactory to find this part of the book artistically treated, by Mr. Woodward, in only 27 pages, which are full of interest. The best memorial of a scientific man is the work that he has done and by which he will be known in the time to come, and it is to Mr. Gunn's work that the editors chefly direct our attention. After, the many contractions of the contraction of the contraction

For the task of bringing these matters before the public no better editors could have been chosen. One of them, who, in his Geological Survey work, was brought much in contact with Mr Gunn, may be called the hereditary geologist of Norfolk. The other has for some years

given great attention to the study of the fossil Mammalia of the Forest Bed, and indeed has made himself the chief authority on the subject.

In 1864, Mr Gunn helped to found the Norwich Geological Society, of which he was the first and the last Plesident, returing from that post only for six years. (1877–83) in order that it should be filled by officers of the Geological Survey who were stationed in Norfolk and Suffolk a graceful compliment. He was also one of the founders of the Norfolk Archeological Society, and an active member of the Norwich Science Gossi Citub, and a member of the Norwich Science Gossi Citub, and a member of the Norwich Museum, which he enriched by his fine collection of fossil mammark.

Now that coal has been found underground at Dover, and that there may be some chance of a search for it being made in the Eastern Counties, it should be remembered that Mr Gunn was the first to advocate that-work in Norfolk

On the ground that "unanimity does not prevail in regard to the nomenclature of the strate "of the Strafe (cliffs, Mr. Woodward gives a useful table, on p. 60. showing the classifications of Guinn, of Presitiveth, and of C. Keid, but that of Wood might have been added with advantage, and he draws attention to the fact that the cliffs are cut back greatly year by year, so that earlier observers may have seen something different from later ones. As the loss of coast is still going on, and the Forest Bed seems not to reach far inland, a happy time may come when that Series will cease to furnish any ground for contention in this matter the geologists of the future may have to take the work of their foregoers, without the luxury of upsetting it.

In his account of the Forest Bed Series, Mr Gunn holds to the view that, as a rule, the trees given on the spots where the stumps are now found. He describes firstly the Estamane Soil, then the Forest Bed proper, then the Reconstructed Forest Bed (a division not historie recognized, and hardly likely to be, reconstruction seeming to occur in various parts of the Series) and lastly the Unio and Rootles Bed; but it should be noted that other observers take the Forest Bed and the Rootles Bed to be one. His use of the term Lammated Beds, for the immediate successor of the Forest Bed Series, is unfortunate, as such names usually are, for lammation is common in the Chillesford Chy below and in some of the Glacial Drift above.

Mr Gunn's notes conclude with remarks, in some detail, on the Proboscides of the Norwich Crag and of the Forest Bed Series, and on the Cervidæ of the latter, chiefly based, with the plates, on the specimens which so liberally gave to the Norwich Museum. The notes are followed by a list of his geological and archaeological papers, ranging over forty-eight years, from 184 bot 1857.

The plates of Mammalian fossils are well executed; but it is a pity that those of Proboscidea and those of Cervidic are not numbered consecutively, instead of independently. The portrait that forms the frontispiece is a good one, and the book is well printed.

Few geologists can expect their names to be handed down to posterity by so fine a set of specimens as those of the Gunn Collection in the Norwich Museum, and by so interesting a literary accompaniment as that now noticed.

OUR BOOK SHELF.

The Melanesians: Studies in their Anthropology and Folk Press. 1891)

IN this book Dr. Codrington gives us the results of observations and inquiries made in the Melanesian Islands from 1863, when he first visited them, to 1887, when he left the Melanesian Mission He does not profess to He does not profess to offer a complete account of the Melanesian people, nevertheless, the work is one of great value, for it is in the main a record, not of what I uropeans say about the natives, but of what the natives say about themselves The most careful of European inquirers may, of course, mistake the real significance of what natives tell them, but Dr Codrington seems to have been at all times fully conscious of this danger, and to have done his best to guard against it

He begins with a chapter on the discovery of the Melanesian Islands, and on their geology and zoology The ethnology of Melanesia he does not attempt to deal with, but he discusses thoroughly the facts relating to kinship and marriage connection among the Melanesians, starting with the proposition that the division of the people into two or more classes, which are exogamous, and in which descent is traced through the mither, is the foundation of native society. He also gives a good account of the position of the chiefs. A chapter is devoted to property and inheritance, and this is followed by a description of secret societies and clubs, a knowledge of both of which is essential to a proper comprehension

of Melanesian life

The religion of the Melanesians, like that of all savage and barbarous peoples, is a subject of great difficulty, but Dr Codrington is able to present clearly what seem to be at least its main outlines. Students of the evolution of religious conceptions will read with especial interest what he has to say about "mana," a supernatural power or influence which is supposed to act in all kinds of ways for good and evil, and which everyone tries to possess or control. The objects of worship are spirits, some of which were formerly men, while others belong to an inde-pendent and higher class All these beings are full of pendent and higher class mana," and many suggestive facts about the popular belief in them will be found in the chapters on sacrifices, prayers, spirits, sacred places and things, magic, possession, and intercourse with ghosis There are also good chapters on birth, childhood, and marriage, death, burial, and "after death."

The chapters on the arts of life, and on dances, music, and games, contain an immense number of interesting facts, well arranged, and in a chapter entitled "Miscellaneous," the author treats of several disconnected subjects, such as cannibalism, head taking, and castaways The concluding chapter is in some respects the best of all. It consists of stories, divided into three groups—animal stories, myths and tales of origins, and wonder These stories are not only pleasant to read, but provide excellent materials for those who devote themselves to the comparative study of folk-tales.

We may note that there are some very good illustrations, especially in the chapter on the arts of life.

Guide to Examinations in Physiography, and Answers 10 Questions By W Jerome Harrison, F G S. (London Blackie and Son, 1891)

THE author of this little work of forty-eight pages is well known as a successful teacher, of wide experience in connection with classes recognized by the Science and Art Department. It is sowedly a guide to the art of passing an examination, the author giving it as his opinion that "knowledge of any subject is not the only requisite to successfully passing an examination in it."

Unfortunately, this is, to a certain extent, true Some candidates are upt to make an injudicious choice of questions, while others, again, spend too little time in studying them, and consequently wander from the point Few who read Mr Harrison's notes will fail to profit by the sound advice which he gives

The first part gives general information about the Science and Art Department and its objects, and applies equally to all the subjects in which its exami-nations are held. The questions which have been given in the elemen y stage since 1882 are answered in

the examiners

A Difficulty in Weismannism

WEISMANN'S theories of heredity and sexual reproduction have been criticized from many a friest points of view. The following remarks are an attempt to apply to his theory of reprofollowing remarks are an attempt to appry to an and assuming its duction a test familiar to the mathematician, and assuming its truth, to follow out the deductions from this assumption. The result is a startling one. I believe the following theses will be accepted as an impartial statement of the main points of the

accepted as an imperation of the form of the form of the form of ancestral germ units, the Ahnenplasmas, and this number is constant, for the species at least.

If These ancestral germ-units are far more constant and un-changeable in character than the species itself.

changeable in character than the species useff.

III They lie associated together in the germ cell without loss or alteration of their neidwidsal personalities.

IV The number commends and the constraint of the Athendraint of the or packs of cards by taking that from each and poung the lathour or renundents to lorm a new constraint of the constraint of

V. The possible combinations under this process are so numerous as to explain the variations among the offspring of sexual

Accepting these statements, we next inquire, How are we to conceive of these ancestral units, the Ahnenplasmas? Two hypotheses may be given in answer to this question !--A Each Ahnenplasma unit corresponds to an individual of

"A Each Ahnenplasma want corresponds to an individual of the speces itself, and if put ander proper trophec conditions would, amply, reproduce such an individual would, amply, reproduce such an individual consideration of the produce such an individual consideration of the produce modification of the case of the produce modifications due to external essues (sequired modifications) According to hypothesia A, the Ahnenplasma of living, and so we get Protechouldie, and finally Protometissua and so we get Protechouldie, and finally Protometissua Ahnenplasmas in the gern cells for one more and more remote anecessor. In other words, the Ahnenplasma have warrel is more toolly renders the shuffling process unnecessary to evolution to only renders the shuffling process unnecessary to evolution.

actionately, and at the sum 'are with the suc. This inference ont only renders the shelling process unnecessity to explain variation, but it is inconsistent with these II., the very foundation of Wessmann is theory of heredit with the sum of the sum of

"Hereditary variability can only arise in the lowest unreello organisms; and necessarily passed over into the higher organi when they first appeared" (Weismann, "On Heredity." English edit p 299). The passage would seem to render hyp thesis "necessity for

Rain-making Experiments

YOUR last number contains an article by Prof Curtis on the "rain-making" experiments in Texas, in which no reference is made to the report published in the October number of the North unale to the report published in the October number of the Norial Austraca Kiraw by General Dyreaforth, who directed the operations. I wish to call altention to the remarkable difference which easist between the statements of Prol Curus, the meteorologist of the expedition, and General Dyreaforth, its director countries of the expedition, and General Dyreaforth is director even of the traperments, believes that only thangy howers or "good grass rain" fell. General Dyreaforth says the amount was nearly a Inches. On August 18, Prof Curus sus pathat only 0.02 inch of rain fell; General Dyreaforth says that will dreach a manifell in Ceneral Dyreaforth says the amount arise fill in toreas for two and a faith fours," and that driving from the excampment to Midland, a dutance of a 3 miles, of water. It is a minosable, under these circumstances for those road traversed was covered for \$6 or \$8 miles under \$4\$ to \$6 miles of water. It is impossible, under these cromustances, for those of water and the impossible that these cross the same and the same a is evident that the explosions of hydrogen and oxygen, on wincome General Dyrenforth relies so much, are useless, and that the smoke-producing rackatock does all the work. In an extremely sceptical and very justly cruical article, which follows that of General Dyrenforth in the North American Review. that of General Dyrenforth in the North American Revenue, Prof. Simon Newcomb, while scouting the "concussion" theories of General Dyrenforth, says, indeed, that smoke particles may possibly serve as nuclei for the condensation of water vapour, but he is evidently unacquainted with the re-markalite work of Mr. Autken, which throws so much light on the matter

Manchester, October 24.

A Rare Phenomenon.

HAVING just returned from Norway, it may be of interest to record inhat the hand of light which was observed by many of your correspondents on September 11, was remarkably williast in N lat, 52°, extending from the horison to the zenith, but not beyond. It was nearly, but not quite, equal in width throughout the 50°, and therefore must either have been much wider at the base than at the speez, or else at an immense alti-Some clue to the estimation of this altitude would be afforded by an accurate record of the zenith distance as observed in Lingland.

I may add that the aurora borealis was distinctly visible in the north and north west at the same time, but this band rose from north and north west at the same time, but this band rose from the tonth-east, which ied me to conjecture that it might belong to a comet; however, on the following night it did not recur, and it then thought it might have been caused by some san-hit cirra at a great elevation, but it is now obvious that this was not the case. The remarkable feature was its concurrence with, and yet apparent difference from, the ordinary autora. Richmood, Surrey, October 24. W. DUPFA-CROTKA.

THE phenomenon obserged by Dr. Copeland (NATURE, September 24, p 494) at 11.18 pm. on September 10 at Dunccht, by Mr. W. E. Wilson at 9 pm. on September 11 m Co. Westmeath, and by other observers on the 11th in

NO. 1148, VOL. 44]

several parts of England, was observed by a party of three, including myself, at 9 30 p.m. on September 25 at Ballater, Aberdeenshire.

nergeensnire.
It appeared as an inten-e white beam of light stretchin. It appeared as an interie white beam of light stretching from east to seat and directly overhead, of uniform width and perfectly steady II exemed quite low down, almost as if it might light up the summit of the church spire were it moved a little further towards the south At III.30 the light had become diffuse, and it appeared at a much greater elevation, though maintaining its general direction from east to west.

Earthquake at Bournemouth

Wa had a sharp momentary shock of earthquake here at four o'clock this afternoon. I happened to have my eyes fixed on a plant with long variegated leaves on my dining-room table. Suddenly there was a heavy sound as of some subterranean fall, and simultaneously the leaves of this plant were violently agiand simultaneously the leaves of this plant were violently agi-lated—waved up and down—for some seconds. It was as if it lad risen vertically and then failen It was wholly unmoved by so much as a tremor the rest of the afternoon. I tred to reproduce anything like the same disturbance by band, but with out success.

Bregner, Bournemouth, October 25.

W = M_s

I had read Mr Slate's letter (Nature, vol. xliv p. 445), and admired R, moreover, I found myself in agreement with him. But it seems to me strange that Prof. Greenfull should approve of R. For Mr Slate takes as his gravitational unit of him. But it seems to me strange that Prof. Greenhill should approve of it. For Mr Slate takes as his gravitational unit of force "the swagest of one pound under cravastiances specified with the thorsity of the swagest of one pound under cravastiances specified with the three sizes (Prof. Greenhill's food) when they say that "the weight of a given body depends on the local value of \(\frac{t}{2} \). Prof. Greenhill's on the contrary, speaking of goods, any that (Prof. Greenhill's and the prof. (BAFURLYO) six possible speaking of goods, any that (BAFURLYO) six possible speaking to good the prof. (BAFURLYO) six possible speaking the speaking the prof. (BAFURLYO) six possible speaking the speaking t

and sub-multiples. Hence the every-day, slightly ambiguous, use of the word "weight" in matters in which we are not concerned with mertia. But in the science of dynamics, of which Newton's with inertia. But in the science of dynamics, of with Newton's laws are the foundation, we are concerned printerly with the well-known lump of pistunum as the standard pound, the British sunt of mass. They thus have the word "weight" for, and any (ε, χ) that the weight of the standard pound is measured by the standard pound in measured by the standard pound on the bottom of the standard pressure that it can ref (in vacco) on the bottom of the risultant pressure that it exerts (in watco) on see some of very the visit and first. It requires more than general expressions of condemnation to show that say other system of nonenculatures as clearer or less free from ambiguary, or that the egastion W = Mg has not as much mening as any other dynamical equation. (I may refer back to my letter, NATUER, vol. xiv. ADD.

p. 493). Devonport, September 26.

SOME NOTES ON THE FRANKFORT INTER-NATIONAL ELECTRICAL EXHIBITION!

Alternate Current Motors.

A LTERNATE current motors constitute one of the most striking features at the Frankfort Exhibition, and the commercial use of such motors will probably date from this year, so that the one great objection to the endogram of the commercial use of the commercial to the electric transmission and distribution of power will soon dis-

appear.

It is well known that the direction of rotation of an ordinary series, or shunt, direct current motor is the same whichever was the direct current motor is the same whichever was the direct current passes round the motor, in spite of a patent of Mr. Edison's to utilize the contrary fact on electric railways, hence it follows that if an alternate current be sent round such a motor it will start rotating and develop mechanical power. Only a com-

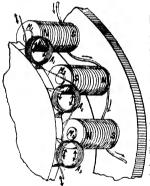

Fig 10 -Alternate current synchronizing motor -> Alternating current

paratively small power and efficiency, however, will be obtained: first, because the large self-undurion of the field magnet of the motor will seriously diminush the strength of the alternating current; secondly, because, in consequence of the rapid reversals of the magnetism, much power will be wasted in heating the iron core of the field magnet, even although this core be laminated like that of the armature.

He can to the armature. If, on the other hand, a direct current be sent round the field magnet, M_1 , M_2 , M_3 , of an alternate current machine, and an alternating current rough the armature, A_1 , A_2 , A_3 , A_4 , (Fig 10), the armature will not move, because at every two of the successive rapid reversals of the current the armature receives an impulse in opposite directions. To enable such a machine to work as a monor.

Continued from p 546.

NO. 1148, VOL. 441

It is necessary to first make the armatuse rapidly rotate by mechanical means at such a speed that any armature coil, A., mores forward by the distance being any armature coil, A., mores forward by the distance being armature coil, A., mores forward by the distance being at the periodic time of the alternation of the current. When this speed has been once attained, the machine will go or numing as a powerful and efficient alternate current motor, at a percety definite speed, dejending simply on the rate of alternation of the current, and independent within wide limits of the load put on the motor.

So that when the armature of the motor is once "in step" with that of the dynamo the two will continue "in step," whatever be the amount, within wide limits, of the power transmitted

When a considerable amount of power has to be sent from a source to a distant town, and has there to be distributed for light or for driving machinery, it will certainly be best (as far as our present knowledge goes) to use alternating currents in the transmission of the power between the two distant places, because with alternating currents the pressure can so easily be transmissing currents the pressure can so easily be transmissing currents the pressure can so easily be transmission.

But in the distribution of the received power direct currents are the more convenient, since they can be utilized for light, for electroplating and electrotyping,

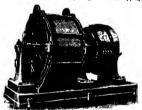

Fig. 11 -Coupled alternate current meter an intentiture it dynamo

as well as for small and large duert current electromotors, both of which have already eached a considerable degree of perfection, and are of course selfstarting. Hence it is probable that there will be imployed a synchronizing alternate current motor, coupled mechanically to a direct current dynamo, the latter being used to supply current to the town and excite the field magnets of the motor. Such combinations, seen in Fig. 11, are exhibited by Messra Steinens and Halske in the Irankfort Exhibition, the alternate current motor being to the left and the direct current of the properties of the left and the direct current of the properties of the left and the direct current of the properties of the left and the direct current of the properties of the left and the direct current of the properties of the latter and the properties of the prope

In the particular form of direct current dynamo shown in Fig. 11, and which represents a type much used now on the Continent, the field magnets are inside the rotating armature, and the wires on the outside of the Gramme ring itself are bare, and act as the commutator.

The impossibility of starting the simple synchronizing motor with an alternating current will be of little consecutions.

The impossibility of starting the simple synchronizing motor with an alternating current will be of little consequence when a large amount of power has to be transmitted, seeing that in the receiving station there will be several sets of generic alternate current motors and direct current dynamos, some of which will be always rouning day and night. Hence, to start any alternate current motor, all that need be done will be to send round the direct current

dynamo, attached to the motor to be started, a portion of the direct current that is being produced by one of the running dynamos. This will cause the stationary direct running dynamos. Inis will cause the stationary direct current dynamo to start running as a motor, and when the right speed has been attained—that is, when the motor is in step with the distant alternate current dynamo—the alternate current can be switched on to the alternate current motor

Actual plans are being seriously got out at the present time, for using this exact method to transmit 5000 horsepower over forty miles in Tasmania, the received power being transformed by ten such combinations as are seen

in Fig 11, each of 500 horse power.

This subdivision of the machinery at the receiving generating plant at the sending end of the line, will have another most important advantage, viz that a breakdown of a dynamo or of a motor will not cause a stoppage in the supply of power. A factory 15, no doubt, worked at present with a single large engine; the propulsion of a steamer depends on the turning of a single powerful screw, but neither the unexpected stoppage of the factory engine for say half-an-hour once every two or three months, nor the delay of an Atlantic liner in mid-ocean for the same time once in every half-dozen voyages, would necessarily mean run Were, however, the 10,000 horse power dynamo at Deptford to be ever finished and worked at its full output, it would be necessary, in order to avoid a temporary hitch leading to the turning off the current from many thousands of glow lamps, and the plunging of a neighbourhood into darkness, to always have dynamos of a capacity of 10,000 horsepower kept idle in reserve

Experience has shown that the size of each dynamo in a maximum output, and that it is sufficient to keep one, or at the most two such dynamos, as a reserve, to prevent temporary breakdowns interfering with the steady is lighting some 500,000 glow lamps or more than ten times the total number at present attached to the mains of the London Electric Supply Corporation—no one but the Brunel of electricity would have had the courage to embark on a 10,000 horse-power machine

At any rate, when during the next year or two it is required to transmit a large amount of power over a considerable distance, it is probable that several alternate current synchronizing motors, each coupled to a direct current dynamo, will be employed at the receiving end of

the line

In cases, however, where there already exists an extended system of distributing alternate currents for electric light, the introduction of motors into small workshops and private houses will hardly be possible, unless the motors can be made self-starting Mr Zipernowski's motors, employed for driving the tools in a curpenter's shop at the Frankfort Exhibition, have been made selfstarting, and also fairly efficient, by adopting a compromise between the simple direct current motor, which is self-starting but inefficient when used with alternating currents, and the alternate current synchronizing motor, which is efficient but not self-starting.

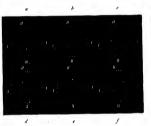

The device employed by Mr Zipernowski, and which is based on a communication made by Prof. G Forbes to the Royal Society of Edinburgh some eight years ago, is as follows: -- Send the alternating current round the field magnet as well as round the armature of an alternate current motor (Fig 10), and attach a commutator to the armature so as to reverse the current flowing round the field magnet every time the armature coils A₁, A₂, A₃ pass the field magnet coils M₁, M₂, M₃ On sending the alternate current round such a motor, the motor will start, but since at first the rapidity of alternation of the current will be far greater than the rapidity of commutation there cates the position which in each case would be taken up

will be much sparking at the commutator and waste of power As, however, the armature turns more and more quickly, the commutation will be effected more more query, the commutation will be effected more and more rapidly, until at last the armature will attain such a speed that every time the current is reversed by the distant dynamo the portion of the current flowing round the field magnet of the motor will be commutated by the rapidly rotating armature. Hence the current flowing round this field magnet will now be always in the same direction. But as it will not be always of the same strength there will be more waste of power than with a simple synchronizing motor

Such an arrangement as that adopted by Mr. Zipernowski, then, furnishes a motor which, although not as efficient and powerful for its weight as the synchronizing motor previously described, has the advantage of synchronizing fairly well, of being self-starting, and of giving far betterresults than a direct current motor with laminated field magnets used with alternating currents.

It is possible, however, as proved by Prof Ferraris in

1885, to design an alternate current motor on totally different principles, and to construct a machine which will work not merely without a commutator, but without even any sort of rubbing contact So that, in fact, the

Fit 12 -Rotating magnetic field produced by two alternating currents

ends of all the wires on a Ferraris motor may be per-manently soldered, and the motor left in the hands of a person who knows how to oil a machine but who is quite ignorant of the trimming and adjustment of the brushes of an ordinary direct current motor

Round an iron ring are wound four coils, as seen in Fig. 12, and through the two distinct circuits are sent two harmonic alternating currents having the same periodic time and maximum amptitude, but differing by 90° in phase. The ring will therefore receive two magnetizations along two fixed diameters at right angles to one another, the two magnetizations alternating approximately according to the sine function of the time, and differing by 90° in phase. And the composition of these two magnetizations will give a "rotating magnetic field," which will make one complete rotation in the periodic time of alternation of the current.

Six values of these two currents are indicated in Fig. 12, the currents in a, c, and e, being of their maximum value in coils 1, 12, and nought in coils 11, 112; while in b, d, and f, the currents in the four coils are equal, 1 of the maximum value. The arrow indiby a suspended compass needle, the point of the arrow indicating the north-seeking pole of the compass needle. If in place of the suspended compass needle there be a piece of copper, currents will be induced in this copper by

If in place of the suspended compass needle there be a piece of copper, currents will be induced in this copper by the rotating magnetic field, tending to make the cylinder produced in the same considerable of the region of the ring, and supported so that it can rotate about this axis, the cylinder will the axis coinciding with the axis of the ring, and supported so that it can rotate about this axis, the cylinder will run after the rotating field until it catches it up, when the two will move nearly synchronously together that is, on making the motor do work—the speed of the cylinder will be checked, but a small diminution of speed will cause large curients to be induced in the copper, and a pulling force to be exerted between the rotating round. Hence this arrangement of Prof Ferraris produces not merely a self-starting alternate current motor, but one which runs aimost synchronously with the dynamo for wide variations in the load, and which has neither conventions of the control of the control

Within the past few weeks we have learnt that the idea of obtaining a rotating magnetic field was mentioned by M. Marcel Deprez, in a French patent dated May

the copper cylinder originally used by Prof. Ferrans was next made hollow, and the interno filled with soft iron, the iron being laminated in planes at right angles to the axis, to prevent currents being induced in the iron; and to make the currents induced in the copper cylinder follow the most useful path the next step was to make a number of cuts through the hollow copper cylinder parallel to the axis of rotation Practically, then, the rotating portion becomes a luminated cylinder for iron, on which is Semens armature, but with end for the cylinder some cleaning the complex properties of the cylinder of the cyli

A two-phase alternate current motor was constructed and used by Piof Ferrars in his laboratory at Turn in 1885. But not appreciating the practical importance of an own invention, and thinking that no motor requiring his own invention, and thinking that no motor requiring philosopher, Prof Ferrars occupied himself with attempts to utilize the rotatory magnetic field in measuring the reastance of conductors and with mathematical investigations on alternate currents. If was not, therefore, until coins on alternate currents if was not provided in the published; when, a few months later, commercial motors based on exactly the same punciples were brought ory.

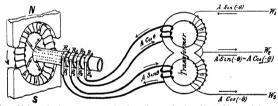

FIG. 13.—Schuckeri two-phase alternate current generator and transformer the arrows indicate the actual direction of the currents for the position of the armature shown

1883. In that patent, when speaking of the magnetic field produced by the current flowing round a Gramme ring, he says: "I celte rolation duckamp magnetique peut des obtains and fune moverous causes picks, pour ela obtain sur fune moverous causes picks, pour ela obtain sur la comparte de sharpe di audi des responsable de la formation de la familia de ce champ terra alors une retuitaine dont la position di pond des intensités relatives des deux courants auns que ceta a el décret ca desses pour le comparateur des courants, il suffi de faire varier te rapport de cause de la courants, il suffi de faire varier te rapport de champ magnetiques commerciels residents, a vive cette le champ magnetiques commerciels residents, a vive cette le

It does not, however, appear to have occurred to M. Deprex that this rotation of a magnetic field might be employed to induce currents, and thus give motion to a piece of metal placed inside the Grammering; nor does he say by 90° in phase producing the exact variation of current required. Although, then, what may be called the geometrical idea of producing a rotating magnetic field was certainly clearly described by M. Depres, the credit of freedrich producing the control of applying it in the design of the two-phase alternate current motor, is due to Prof. Ferrans

To increase the strength of the rotating magnetic field,

with considerable & lat by Mr Tesla, of Pittsburg, who had been working independently in the same direction.

To produce two alternate currents, differing by 90' in phase, the following device (Fig. 13) may be adopted, and is the one employed by Messrs Schuckert in transituting power at 2000 volts from the Palm Garden at Frankfert to the Exhibition, and by Messrs Stemens and Frankfert to the Exhibition, and by Messrs Stemens and Haiske for experiments in rotatory field alternate current not employing the special form of transformer shows anymbolically in Fig. 13. In addition to the armature of a Graname dynamo being joined up in the well-known way with the ordinary direct current commutator (this commutator and brushes rubbing on it not being shown in Fig. 13). In addition to the armature on the fig. 13, In the property of the commutator of the property of the commutator and brushes rubbing on it not being shown in Fig. 13). In the property of the metal rings, R₁, R₂, R₃, and R₄, which rotate with the machine is producing a direct current, used for exciting the field magnets as well as for any other purpose desired, the current passing through the wires brushes B₁, B₂, and the current passing through the wires brushes B₃, B₄, and the current passing through the wires as the since function of the time, the one reaching its maximum value when the other is nought.

The actual machine employed for this purpose by direct current, it will rotate as a motor generating the Mestrs. Schucket is the multiplient dynamo shown in two identate currents, and also doing mechanical work Fig. 14, the direct current commitator and brushes, as if required, lastly, if supplied with the two alternate well as the four rings and brushes for the two alternating cu tents, it will wook as a twe-phase alternate current.

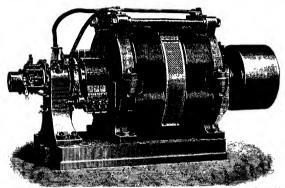

Fig. 14 -Schuckert's two-plane alternate current gene

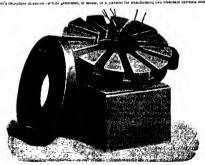

Fig. 15 -- Schuckert two-phase alternate current transformer (method of construction).

currents, being here seen. If rotated mechanically, it motor generating a direct current, as well as design will produce a direct current, as well as two alternating mechanical work.

currents differing by 90' in planse, if supplied with a | When transmitting power to a distance, the iwo-phase

alternate potential differences are transformed up from about 100 to 2000 volts; and to enable the transmission to be effected with three wires instead of four, Messis Schuckert arrange the transformer at each end of the line

The actual method employed by Messrs. Schuckert for winding this special transformer, as well as its appearance when completed, are seen from Figs. 15 and 16. This transformer, then, instead of consisting of merely a double

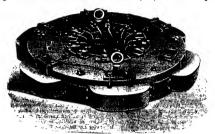

Fig. 16 -Schuckers two 1 b ve alternate correct transformer (completed)

as shown symbolically in Fig. 13. Hence, if the currents produced by the dynamo be represented by A $\sin\theta$ and A $\cos\theta$, the currents in the man wires, W, Wi, and W, will be represented by A $\cos(-\theta)$, A $\sin(-\theta)$, and A $\sin(-\theta) + \cos(-\theta)$ respectively.

ring of laminated iron as indicated in the symbolical diagram, Fig. 13, may be regarded as being composed of a connected series of laminated iron rings, each of a wedge-shaped cross-section

(To be continued)

THE OXFORD UNIVERSITY MUSEUM

THE following memorandum is based, not only upon observations made during a recent visit to Oxford, but also upon a fairly intimate knowledge of the origin and progress of the different de participate of the Muscuin, acquired at various intervals of time extending over more than thirty veers.

In entering upon the consideration of the subject which you have referred to me, it will first be necessary to define the purposes for which the Museum is maintained. These I take to be somewhat mainfold, but they may be classed.

I take to be somewhat manifold, but they may be classed as follows:—

A. The first and main purpose is undoubtedly to assist in the educational work of the University, by illustrating

the teaching of the professors and lecturers
Besides this, however, it subserves, to a greater or less
degree, other and what may be considered, as compared
with the first, secondary, but nevertheless important functions. These sie—
B. The exhibition of a collection, arranged in a sys-

B. The exhibition of a collection, arranged in a systematic, orderly, and attractive manner, open to the inspection, under proper regulations, of all members of the colony, which shall tend to sawken and keep up an interest in various subjects of which most educated persons, besides those actually engaged at the moment in obtaining materiality, dearer to possess some knowledge. Such as a space of general culture adjunct to the University.

C. Certain collections have already, and possibly will in future, become added to the general Museum, the aim and scope of which reach beyond either of the above,

Prof Flower's Report to the Committee on Collections appointed by the Delegates of the University Muscum, Oxford, dated March 14, 1891

NO. 1148, VOL. 44]

being of value, not to the ordinary student, not to the man or winnan of average general culture, but only to the advanced student who wishes to enter seriously into the pursuit of some special branch of knowledge Such is the Hope Collection of Insectis, and to a certain extent

the Pitt-Rivers Ethnographical Collection
It is a grave question how far such collections should be
maintained at the cost of the University. On the one
hand, they must be a cusse of eyenes, without which no
langer and better ordered they are, the greater must be
larger and better ordered they are, the greater must be
thegoest of maintaining them. Unless properly cared for,
not only as regards actual preservation of the objects
arrangements and augmentations necessitated by the advance of science, they will become comparatively valueless
in the course of time. If the care of many such collections were undertaken unaccompanied by special endowsuch as only a pational institution could afford. Become

On the other hand, looking at the University, not merely as a place for the education of youth, but also as a center of culture for the whole country, the possessor, or some such culticroins is of person for the country, the control of the country, but also as the person of the country, but also from distant places, to wast the University, or even to become permanent real-subjects interesting to scholarly whose numbers are very limited, have long been recognized. From the same point of vew, special collections of rive specimens of natural history or works of art may take their place in the general history or works of art may take their place in the general collections.

sideration as to whether the means will be forthcoming to maintain them in a state of efficiency

I have alluded to the Put-Rivers Collection as coming partly under this head, but, admirably and instructively displayed as it now is, it may also be considered as belonging to my second category; and the numerous human interests awakened by a study of its contents, and the many branches of culture it comes in contact with make it an adjunct to the Museum, of the great importance of which no one should entertain a doubt I should be glad to remark, in passing that the building in which it is housed appears to me the most successful, as regards economy of space, capacity for orderly arrangement, and good lighting, of any with which I am acquainted

The next point for consideration is the nature and extent of the subjects to be illustrated in the Museum (excluding the special Pitt-Rivers Collection just referred to). These seem already to have been determined as including inese seem aireacy to nave oeen cereimined as infusing physiology, human anatomy, comparative anatomy, animal morphology, geology, pathological anatomy, pakrontology, geology, and mineralogy, therefore the whole of animal biology (botany being provided for elsewhere), with the addition of geology and mineralogy. The teaching of these subjects is divided between the Regius Professor of Medicine, the Waynstete Professor of Physiology, the Linacre Professor of Human and Comparative Anatomy, the Lecturer in Human Anatomy, the Hope Professor of Zoology, the Professors of Geology and of Mineralogy It must be recognized by everyone that the boundaries of these subjects are most difficult to define, and must be constantly shifting with the advance of knowledge instance, comparative anatomy and paleontology may both be included under the broad general heading of zoology, which without the aid of both can be but imperfectly understood Whatever dividing lines are drawn between different sections of the collection, identical specimens are often required to illustrate more than one subject. The remains of extinct animals are required to complete the story of their living representatives, they are also required to illustrate the ancient history of the earth, and to define the progress of geological time and the order and succession of strata The relation between the collections used to illustrate the teaching of the Waynflete. the Line e, and the Hope Professors, must also be more or less arbitrary and artificial. In all these matters mutual convenience must be studied, and the specimens which he on the borderland of two subjects should be made in some way available for the teaching of both, otherwise a great duplication will be necessary

With regard to general administration, it appears to me desirable that there should be a governing body for the whole Museum, comparable to the standing com-mittee of the Trustees of the British Museum, or the Museum Committee of the Royal College of Surgeons, or the Museums Syndicate of the University of Cambridge. The Delegates constitute such a body at Oxford, but possibly their constitution or powers might be modified and more clearly defined than they seem to be at present

This body should be composed of members of the University specially selected for fitness for the office; seven or nine would probably be the most convenient number, so that representatives may be found upon it of various branches of science included in the Museum, and also some members of general business or administrative capacity. They should meet at occasional and stated intervals, and should determine general questions affecting the Museum as a whole, the relations of its component elements one to another, the allotment of space and the apportionment of the grants for the service of each department, the general control of expenditure, and also the care of the building, furniture, &c It is not advisable that they should interfere with the details of the arrangement of each department as long as these appear to be

The Keeper of the Museum satisfactorily carried out. should be the active executive officer of this governing body, carrying out their views in the intervals of the meetings, and bringing before their notice any subjects which seem to require their consideration

Each professor, as the representative of the most advanced state of knowledge of his subject, should be the responsible curator of the specimens belonging to his department, having such assistance provided him as may be needful He should be called upon to present to the governing body an annual report of the condition of the collections under his care, and of the accessions which

The actual specimens in the various collections will naturally arrange themselves, both as regards the purpose for which they are kept, and their mode of conservation, under three distinct classes

 Norking set, mostly of common objects, which, if damaged, can be leadily replaced, and which can be put at the disposition of the ordinary student to examine and handle Such collections are absolutely essential to practical teaching, but they should form no part of the per-manent Museum of the University, and should be kept in the rooms specially devoted to study

2 The permanent exhibited series displayed in the grand court and corridors of the Museum, the use of which, in addition to teaching students, is referred to under the heading B, near the beginning of this report Great care is required in selecting and arranging these, as well as in their preservation and display. Every specimen exhibited should have a definite object, and should be so placed that it can be thoroughly well seen
As a general rule they should be so arranged as to show what they are intended to teach without moving them from their places, and if this must be done under proper restrictions, all due precautions should be used that they do not become damaged or destroyed Although for the purposes of custody, arrangement, and nomenclature, these must be under the care of a particular professor. they are in a certain sense the common property of all who have a right of access to the Museum. This is another reason for not removing them from their places (apart from the injury that might thereby accrue to them) without definite cause, as they should be always available for study, the pro'essors and demonstrators rather bringing their classes to them than removing them to the class-rooms

The collections kept for advanced researches Although these are not exhibited in the ordinary sense of the word, they should, if retained at all, be kept in a situation and under conditions which make them readily accessible to all who can profit by their examination under suitable regulations Their preservation is of the utmost importance in the progress of science, as among them are often to be found zoological "types," or the individual specimens upon which the name of the species was instituted, and which must be referred to by zoologists for all future time in cases of difficulty in determining that name To permit the loss or deterioration of a "type' specimen is a serious offence in the eyes of the zon-

specimen is a serious ouence in the eyes or the sor-logist. The Hope Collection abounds in such types. Nothing more need be said at present about the first and third of these sections of the Museum, but the second, the exhibited series occupying the body of the great hall, requires consideration in a little more detail.

It is divided at present into—

(1) Mineralogy. Of the value and arrangement of this section I am not competent to speak

(2) Geology. This collection is mainly palæontological, and the arrangement appears to be partly stratigraphical and partly zoological in many groups the collection is rich, but taking it altogether there appears to be a number of unnecessary duplicates, and much rearrangement is required to bring it into good exhibition and teaching order. I would suggest that in a collection illustrating geology (and not the zoology of extinct animals, so often in museums confounded with that science) the stratigraphical arrangement should be followed as strictly as possible, and also that there should be a good series illustrating dynamical geology, or the processes by which that the strating dynamical geology, or the processes by which the strating dynamical geology or the processes by which the strating dynamical geology.

(3) Animal Biology. This section occupies about twothirds of the floor space of the Museum, and is at present broken up into various small series involving much repe tition and duplication, and also difficulty of finding any

particular object or illustration required

In the middle of the hall is a series of specimens merely showing the external appearance of certain groups of animals, stuffed vertebrates and the shells of mollusks, and stony skeletons of corals, &c. If this collection were incorporated in the general series of animal biology, not only would much duplication be avoided, but a more Many of the present specimens of this series, especially the mounted unamnals and birds, are in such bad condition that they have no educational value—they only mulead instead of teaching; but before destroying them they should all be submitted to the examination of some expert in the group to which they belong, as there may be interesting or rare specimens among them, though observer in their oresent condition.

The imperfection of any coological series that does not illustrate extinct as well as recent forms is continually becoming more apparent as science advances, some attempts have already been made to remedy this defect in the zoological series, but a considerable transfer of specimens to it from the department of geology will

result in advantage to both.

By a rearrangement of the biological series, with incorporation of the so-called toological specimens (excluding the Hope Collection, which I presume is always to be kept apart) much economy of space could be effected, and some of the confusion which now appears to evist in this department of the Museum in consequence of the numerous apparently independent series of specimens will be obviated.

will be moviated to the primary arrangement of the bological collection, whether on the physiological for Hunterian system, or upon a system based upon roo-logical classification, will have to be carefully considered Much is to be said for either, but whichever is adopted Much is to be said for either, but whichever is adopted abould follow the method of teaching of the professor and his assistants. The point to be aimed at is that should be such that the professor and his assistants. The point to be aimed at is that have also also the position with other specimens which are related to it, and which should be studied in conjunction with it. As the classification of animals, except as regards the greater divisions, is still a matter of much uncertainty, and continually changing according to the advance of not a satisfactory basis for the arrangement of a collection intended to illustrate principles rather than details On the other hand, the Hunterian system often brings into justaposition specimens related only by some remote analogy of function, and having no real correspondence or homology. Though we have been also the story of the secondary divisions, will, on the whole, be found most convenient.

I am hardly in a position to say how far the Professor bettowed upon it. An ill-arranged mixed of Physiology requires a special collection to illustrate compared to the letters of the alphabet in teaching. Probably the general hological series with the scaling probably the general hological series with the state of the same letters placed in such orderly like sectures, especially as the tendency of modern phy-produce words of counsel and instruction

siology seems to be to separate itself from morphology, and confine itself more to biological chemistry and dynamics

Another question which has been raised is, whether human anatomy, as distinguished from general pology, requires a separate section of the Museum, and how the great and important colles tool of crania of the races of men, which under Prof. Rolleston became one of the special features of the Museum, should be treated and utilized for instruction. These are questions that time will probably solve. Much depends upon the with the will probably solve. Much depends upon the with the of the dates of the Lectures on Human Anatomy, whether the should teach upon a broad and philosophical basis, or of the dates of the Lectures on Human Anatomy, whether has been supported by the examining bodies. But this trenches upon the larger and more complex subject of what should be the aim of the University in keeping up a Medical vision.

the Pathological Collection will, of course, remain as at present under the care of the Professor of Medicine In looking round the Museum at the present time, one of its greatest wants appears to me to be proper labelling.
The different sections of the Museum should be distinctly marked off from each other Every case should have a conspicuous label on the top of it, indicating the nature of its contents Every specimen should have one in-dicating why it is there and what it teaches This will This will involve a large amount of labour and expense in printing. but it is absolutely necessary, if the collections are to fulfil the purpose for which they are formed It is a mistake to spend much time, labour, and cost in oblaining, preparing, and preserving a specimen, and then to stop short of the one thing needed to make it of use. Better have fewer specimens in a complete state. A printing press might be established in the building and kept constantly at work, but as it would be difficult to apportion the claims upon its services of the different curators, it might be better to make an arrangement with the University Press by which labels (of a uniform with the University Press by which labels (of a uniform character) for the whole Museum would be printed at a fixed charge, and paul for out of the funds of the depar-ment requiring them As in a large number of cases only a single copy of a label is required, it is possible that some system of type-writing might be more economical, and nearly, if not quite, as effectual

Of the importance of complete catalogues of every department of the Museum, it would seem almost superfluous to speak, were it not obvious that much is needed

in this respect

Lastly, it appears to me that, although more work-crooms and class-rooms may be necessary for the growing needs of the scientific departments of the University, there is ample space in the present building for some time to come for the exhibited portion of the Misseum time to come for the exhibited portion of the Misseum valuable hispects, and do great credit to the seal and energy of those by whom they have been-brought together, what is really required now is, not so much that they should be increased, at that they should be better arranged, mens should be gradually replaced by better ones. Oxford has done very much in past times to initiate and keep up a high standard of museum work, but it must not be overflowed that great advances are being made in this respect, not only in this country but all over the Countients, work if both laborous and costly, but when done the result is fully commensurate to the labour and expense bestowed upon it. An ill-arranged museum has been well compared to the letters of the alphabet tossed about in-discriminately, necessing in othing; a well-varranged one-down discriminately, necessing in thing; a well-varranged one-produce works of counsel and instruction.

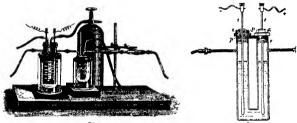

FURTHER RESEARCHES UPON THE ELEMENT FLUORINE.

SINCE the publication by M. Mossan of his celebrated paper in the Annatet de Chimie et de Physique for succeeded in solution by the Annatet de Chimie et de Physique for succeeded in soluting this remetable paesons lement, a considerable amount of additional information has been acquired concerning the chemical behaviour of flaorine, and important additions and improvements have been introduced in the apparatus employed for preparing gathers together the results of these subsequent researches—some of which have been published by him from time to time as contributions to various French scientific journals, while others have not hitherto been made known—and publishes them in a long but most interesting paper Physique. Inamuch as the experiments described are of so extraordinary a nature, owing to the intense chemical activity of flooring, and are so important as filling a long existing vacancy in our chemical literature, readers of NATORE will doubless be interested in a birt account of

IMPROVED APPARATUS FOR PREPARING FLUORINE.

In his paper of 1887, the main outlines of which were given in Nature at the time (1887, vol xxxvi p 179),

This improved form of the apparatus is abown in the accompanying figure (Fig. 1), which is reproduced from the memor of M. Moissan It consist essentially of two parts—the electrolysis apparatus and the purifying vessels. The electrolysis apparatus is sectional release of the electrolysis apparatus, and sectional release across the electrolysis apparatus, a sectional release across the electrolysis apparatus, a sectional release across the electrolysis apparatus, a sectional release across the electrolysis across the electrolysis, across of the limbs of the U-tube. A key of brass, E serves to screw or unscrew the stoppers, and between the flange of each stopper and the top of each branch of the hermetic closing is effected. These fluor-spar stoppers, which are covered with a coating of gum-lac during the electrolysis, carry the electrole rold, r, which are thus perfectly insulated M. Moissan now employs electrodes interior end of each is incheend into a club shape in order the longer to withstand corrosion. The apparatus immersed during the electrolysis in a bath of loquid methyl chloride, maintained in tranquil ebullition at ~25.

PIG I

M. Moissan showed that pure hydrofluoric acid readily dissolves the double fluoride of potassium and hydrogen, and that the liquid this obtained is a good conductor of and that the liquid this obtained is a good conductor of membered that, by passing a strong current of electricity through this liquid contained in a plantum apparatus, free gaseous fluorine was obtained at the positive pole and hydrogen at the negative pole. The amount of hydrodinoric acid employed in these earlier experiments was about fifteen grains, about ax grams of hydrogen polassium flooride, H. E. being added in order to render the strong that the strong and the positive pole and the polassium flooride, H. E. being added in order to render the strong that the strong and important additions have been made, by means of which the fluorine is delivered in a pure state, free from admixed vapour of the very volatile hydroluoric acid, and mayor and admixed vapour of the very volatile hydroluoric acid, and mayor and such the fluorine is delivered by it strong a hydroluoric acid, and more apparatus, and upwards of four litres of pure fluorine is delivered by it per hour.

NO. 1148, VOL. 44]

glass cylinder containing fragments of calcium chloride; by this means it is surrounded with a layer of dry air, a bad conductor of heat The purifying vessels are three in number. The first

consists of a platinum spiral worm-tube, of about 40 cc. capacity, numericed also in a bith ofliquid methyl chloride, maintained at as low a temperature as possible, about 750° As byfordisoric acid bolis at 19° S. (Mossan), almost the whole of the vapour of this substance which is activated at the bottom of the worm. To remove the control and tractical at the bottom of the worm. To remove the control and tractical at the bottom of the worm. To remove the control and tractical at the bottom of the worm. To remove the control and the cont

pressed. During the electrolysis these leaden collars becomes, where exposed to the gaseous fluorine, rapidly converted into lead fluoride, which, being greater in bulk, causes the joints to become hermicially sealed. In order to effect the electrolysis, 26 to 28 Bunnen elements employed, arranged in series. An ampre-emister and a remployed, arranged in series. An ampre-emister and a electrolysis apparatus; the former affording an excellent indication of the progress of the electrolysis.

As the U-tube contains far more hydrofluoric acid than can be used in one day, each lateral delivery-tube is fitted with a metallic screw stopper, so that the experiments may be discontinued at any time, and the apparatus closed
The whole electrolysis vessel is then placed under a glassbell-iar containing dry air, and kept in a refrigerator until again required for use. In this way it may be preserved full of acid for several weeks, ready at any time for the preparation of the gas. Considerable care requires to be exercised not to admit the vapour of methyl chloride into the U-tube, as otherwise violent detonations are liable to occur. When the liquid methyl chloride is being introduced into the cylinder, the whole apparatus becomes surrounded with an atmosphere of its vapour, and as the platinum U-tube is at the same instant suddenly cooled, the vapour is liable to enter by the abducting tubes Consequently, as soon as the current is allowed to pass and fluorine is liberated within the U-tube, an explosion occurs Fluorine instantly decomposes methyl chloride, with production of flame and formation of fluorides of hydrogen and carbon, liberation of chlorine, and occasionally deposition of carbon In order to avoid this unpleasant occurrence, when the methyl chloride is being introduced the ends of the lateral delivery-tubes are attached to long lengths of caoutchouc tubing, supplied at their ends with calcium chloride drying tubes, so as to convey dry air from outside the atmosphere of methyl chloride vapour. If great care is taken to obtain the minimum temperature, this difficulty may be even more simply overcome by employing mixture of well-pounded ice and salt instead of methyl chloride; but there is the counterbalancing disadvantage to be considered, that such a cooling bath requires much in we frequent renewal

CHEMICAL REACTIONS OLCURRING DURING THE ELECTROLYSIS

In the paper of 1887, M. Moissan adopted the view that the first action of the electric current was to effect the decomposition of the composition of the solution in the hydroflore said, thouse the consistency of the hydroflore said, the most experience of the positive pole, and potassium at the negative terminal. This liberated potassium would at once regenerate potassium fluorde in presence of hydrofluoric acid, and liberate its equivalent of hydrogen.

$$KF = K + F$$

 $K + HF = KF + H$

But when the progress of the electrolysis is carefully sollowed, by consulting the indications of the amperemeter placed in circuit, it is found to be by no means as regular as the preceding formulae would indicate. With the new apparatus, the decomposition is quite irregular proceeding for upwards of two hours. Upon stopping the current and unmounting the apparatus, the platinum red apon which the fluorine was liberated is found to be largely corroded, and at the bottom of the U-tube a quantity of a black, finely divided substance is observed. This black substance, which was taken at first to be admitted to the control of the c

complicated than was at first considered to be the case. The maxture of acid and alkaline fluonide furnishes fluorine at the positive terminal rod, but this intensely active gas, in its basecin state, articles, the platinum and case the state of the st

PHYSICAL PROPERTIES OF FIVORINE

Fluorine possesses an odour which M Moissan compares to a mixture of hypochlorous and and nitrogen peroxide, but this odour is sually masked by that of the ozone which it always produces in moist air, owing to its decomposition of the water uppour It produces most serious unitation of the bronchial tubes and mucous membrane of the nisal cavities, the effects of which

membrane of the nasal cavities, the effects of which are persistent for quite a formight. When examined in a thickness of one metre, it is seen to possess a greenish-jellow colour, but paler, and containing more of yellow, than that of chlorine. In such a layer, fluorine does not precent any absorption-bands, alsey, fluorine does not precent any absorption-bands between wave-lengths 744 and 162. Their positions and relative intensities are as follows:

At a temperature of -95° at ordinary atmospheric pressure, fluorine remains gaseous, no sign of liquefaction having been observed

METHODS OF EXPERIMENTING WITH FLUORINF. When it is desired to determine the action of fluorine upon a solid substance, the following method of procedure is adopted A preliminary experiment is first made, in order to obtain some idea as to the degree of energy of the reaction, by bringing a little of the solid, placed upon the lid of a platinum crucible held in a pair preparation apparatus If a gaseous or liquid product results, and it is desirable to collect it for examination, small fragments of the solid are placed in a platinum tube connected to the delivery-tube by flexible platinum tubing or by a screw joint, and the resulting gas may be collected over water or mercury, or the liquid condensed in a cooled cylinder of platinum. In this manner the action of fluorine upon sulphur and todine has been studied. If the solid, phosphorus fer instance, attacks platmum, or the temperature of the reaction is sufficiently high to determine the combination of platinum and fluorine (towards 500'), a tube of fluor-spar is substituted for the platinum tube. The fluor spar tubes employed by M Moissan for the study of the action of phosphorus were about twelve to fourteen centimetres long, and were terminated by platinum ends furnished with flanges and screw threads in order to be able to connect them with the preparation apparatus If it is required to heat the fluor-spar tubes, they are surrounded by a closely wound

copper sparal, which may be heated by a Bunsen flame. In experimenting upon liquids, grait care is necessary, as the reaction frequently occurs with explosive violence. A preliminary experiment is therefore always made, by allowing the fluorine delivery-tube to dup just beneath the wurface of the liquid contained in a small glass cylinder. When the liquid contains water or when

hydrofluoric acid is a product of the reaction, cylinders of platinum or of fluor-spar are employed. If it is re-ouired to collect and examine the product, the liquid is placed along the bottom of a horizontal tube of platinum or fluor-spar, as in case of solids, connected directly with the preparation apparatus, and the product is collected over water or mercury if a gas, or in a cooled platinum receiver if a liquid.

During the examination of liquids a means has accidentally been discovered by which a glass tube may be filled with fluorine gas A few liquids, one of which is carbon tetrachloride, react only very slowly with fluorine at the ordinary temperature By filing a glass tube with such a liquid, and inverting it over a platinum capsule also containing the liquid, it is possible to displace the liquid by fluorine, which, as the walls are wet, does not attack the glass. Or the glass tube may be filled with the liquid, and then the latter poured out, leaving the walls wet, the tube may then be filled with fluorine gas, which, being slightly heavier than air, remains in the tube for some time test-tube had been filled with fluorine over carbon tetrachloride, it was attempted to transfer it to a graduated tube over mercury, but in inclining the test-tube for this purpose, the mercury suddenly came in contact with the fluorine, and absorbed it so instantaneously and with such a violent detonation that both the test-tube and the owing to the powerful affinity of mercury for fluorine, it is a most dangerous experiment to transfer a tube containing fluorine gas, filled according to either the first or second method, to the mercury trough, the tube is always shattered if the mercury comes in contact with the gas, and generally with a loud detonation Fluorine may, however, be preserved for some time in tubes over mercury, provided a few drops of the non reacting liquid

are kept above the inercury meniscus

For studying the action of fluorine on gases, a special piece of apparatus, shown in Fig. 3, has been constructed

It is composed of a tube of platinum, fifteen centimetres long, closed by two plates of clear, transparent, and colourless fluor-spar, and carrying three lateral narrower tubes also of platinum. Two of these tubes face each other in the centre of the apparatus, and serve one for the conveyance of the fluorine and the other of the gas to be experimented upon. The third, which is of someto be experimented upper and unit, which is of some-that greater diameter than the other two, serves as exti-tible for the product or products of the reaction, and may be placed in connection with a trough containing either water or mercury. The apparatus is first filled with the gas to be experimented upon, then the fluoque is allowed to enter, and an observation of what occurs. may be made through the fluor-spar windows. One most important precaution to take in collecting the gaseous products over mercury is not to permit the platinum delivery-tube to dip more than two or at most three

become so different owing to the pressure, that the fluorine from one side mixes with the hydrogen evolved upon the other, and there is a violent explosion.

ACTION OF FLUORINE UPON THE NON-METALLIC

Hydrogen —As just described, hydrogen combines with fluorine, even at - 23° and in the dark, with explosive force This is the only case in which two elementary ga-es unite directly without the intervention of extraneous ga-es unite directly without the intervention of extraneous energy if the end of the tube delivering fluorine is placed in an atmosphere of hydrogen, a very hot blue flame, bordered with red, at once appears at the mouth of the tube, and vapour of hydrofluoric acid is produced.

Ovygen,-Fluorine has not been found capable of uniting with oxygen up to a temperature of 500°. On ozone, however, it appears to exert some action, as will be evident from the following experiment lt was shown in 1887 that fluorine decomposes water, forming hydrofluoric acid, and liberating oxygen in the form of ozone. When a few drops of water are placed in the apparatus shown in Fig 3, and fluorine allowed to enter, the water is instantly decomposed, and on looking through the fluor-spar ends a thick dark cloud is seen over the spot where each drop of water had previously been This cloud soon diminishes in intensity, and is eventually replaced by a beautiful blue gas—ozone in a state of considerable density. If the product is chased out by a stream of nitrogen as soon as the dense cloud is formed, a very strong odour is perceived, different from that of either fluorine or ozone, but which soon gives place to the unmistakable odour of ozone. It appears as if there is at first produced an unstable oxide of fluorine, which rapidly decomposes into fluorine and

Nitrogen and chloring appear not to react with fluorine

Sulphur .- In contact with fluorine gas, sulphur rapidly melts and inflames A gaseous fluoride of sulphur is formed, which possesses a most penetrating odour, somewhat resembling that of chloride of sulphur. The gas wnat resembling that of chloride of sulphur. The gas is incombustible, even in oxygen. When warmed in a glass vessel, the latter becomes etched, owing to the formation of silicon tetrafluoride, 51⁴, Selenium and tellurium behave similarly, but form crystalline solid fluorides

Biomine vapour combines with fluorine in the cold with roduction of a very bright but low-temperature flame. If the fluorine is evolved in the midst of pure dry liquid bromine, the combination is immediate, and occurs without flame

Todine —When fluorine is passed over a fragment of sodine contained in the horizontal tube, combination occurs, with production of a pale flame. A very heavy liquid, colourless when free from dissolved iodine, and furning strongly in the air, condenses in the cooled receiver. This liquid fluoride of iodine attacks glass with great energy, and decomposes water when dropped into that liquid with a noise like that produced by red-bot iron. Its properties agree with those of the fluoride of iodine prepared by Gore by the action of iodine on silver fluoride.

Phosphorus.—Immediately phosphorus, either the ordinary yellow variety or red phosphorus, comes in contact nary yellow variety or red prospronts, comes in contact with fluorine, a most lively action occurs, accompanied by vivid incandescence. If the fluorine is in excess, a furning gas is evolved, which gives up it sexess of fluorine on collecting over mercury, and is soluble in water. This gas is phosphorus pentialluoride, Pf., prepared some years ago by Prof. Thorpe If, on the contrary, the phosphorus is in excess, a gaseous mixture of this pentafluoride with a new fluoride, the trifluoride, PF, millimetres under the mercury, as otherwise the levels of a gas insoluble in water, but which may be absorbed by the liquid in the two limbs of the electrolysis U-tube caustic potash, is obtained. The trifluoride, in turn, combines with more fluorine to form the pentafluoride, the reaction being accompanied by the appearance of a flame of comparatively low temperature.

Arsenic combines with fluorine at the ordinary tem-erature with incandescence If the current of fluorine perature with incandescence. If the current or nuotine is fairly rapid, a colourless furning liquid condenses in the receiver, which is mainly arsenic triflioride, A8F, but which appears also to contain a new fluoride, the pentafluoride, AsF₃, masmuch as the solution in water yields the reactions of both arsenious and arsenic acids

Carbon - Chlorine does not unite with carbon even at the high temperature of the electric arc, but fluorine reacts even at the ordinary temperature with finely-divided carbon. Purified lampblack inflames instantly with great brilliancy, as do also the lighter varieties of wood charcoal A curious phenomenon is noticed with wood charcoal it appears at first to absorb and condense the fluorine, then quite suddenly it bursts into flame with bright scintilla-tions. The denser varities of charcoal require warming to 50° or 60' before they inflame, but if once the combustion is started at any point it rapidly propagates itself throughout the entire piece. Graphite must be heated to just below dull redness in order to effect combination . while the diamond has not yet been attacked by fluorine, even at the temperature of the Bunsen flame. A mixture of gaseous fluorides of carbon are produced whenever carbon of any variety is acted upon by fluorine, the predominating constituent being the tetrafluoride, CF.

Horon—The amorphious variety of boron inflames

instantly in fluorine, with projection of brilliant sparks and liberation of dense fumes of boron triflionide, BF, adamantine modification behaves similarly if powdered When the experiment is performed in the fluor-spar tube, the gaseous fluoride may be collected over mercury The gas fumes strongly in the an, and is in-

stantly decomposed by water

Silicon -The reaction between fluorine and silicon is one of the most beautiful of all these extraordinary manifestations of chemical activity

The cold crystals become immediately white-hot, and the silicon burns with a very hot flame, scattering showers of star-like, white-hot particles in all directions. If the action is stopped before all the silicon is consumed, the residue is found to be As crystalline silicon only melts at a tempera-The control of the co

ACTION OF FLUORINE UPON METALS

Sodium and potassium combine with fluorine with great vigour at ordinary temperatures, becoming incandescent, and forming their respective fluorides, which may be obtained crystallized from water in cubes Metallic calcium also burns in fluorine gas, forming the fused fluorine, and occasionally minute crystals of fluor-spar Thallium is rapidly converted to fluoride at ordinary temperatures, the temperature rising until the metal melts and finally becomes red-hot Powdered magnesium burns with becomes red-hot Powdered magnessum burns with great brilliancy. Iron, reduced by hydrogen, combines in the cold with immediate incandescence, and formation of an anhydrous, readily soluble, white fluoride Aluminium, on heating to low redness, gives a very beautiful luminosity, as do also chromium and manganese. The combustion of slightly warmed zinc in fluorine is particularly pretty as an experiment, the flame being of a most dazzling whiteness. Animony takes fire at the ordinary temperature, and forms a solid white fluoride. Lead and mercury are attacked in the cold, as previously described, the latter with great rapidity. Copper reacts at low redness, but in a strangely feeble manner, and the white fumes formed appear to combine with a further quantity of fluorine to form a perfluoride

The main product is a volatile white fluoride

Sifteer is only slowly attacked in the cold. When heated, however, to 100°, the metal commences to be covered with a yellow coat of anhydrous fluoride, and on heating to low redness combination occurs, with incandescence, and the resulting fluoride becomes fused, and afterwards presents a satin-like aspect. Gold becomes converted into a yellow deliquescent volatile fluoride when heated to low redness, and at a slightly higher temperature the fluoride is dissociated into metallic gold and

fluorine gas. The action of fluorine on platinum has been studied with special care. It is evident, in view of the corrosion of the positive platinum terminal of the electrolysis apparatus, that nascent fluorine rapidly attacks platinum at a temperature of - 23° At 100°, however, fluorine gas a temperature of -23° At 100°, however, huoring gas appears to be without action on plantium. At 500°-500° it is attacked strongly, with formation of the tetra-fluoride, PtF4, and a small quantity of the protofluoride, PtF4. If the fluoriue is admixed with vapour of hydroa fluoric acid, the reaction is much more vigorous, as if a fluorhydrate of the tetrafluoride, perhaps 21HF PtF₆, were formed The tetrafluoride is generally found in the form of deep-red fused masses, or small yellow crysta's resembling those of anhydrous platinum chloride resembling those of anhydrous platinum choride I had salt is volatile and very hygroscopic. Its behaviour with water is peculiar With a small quantity of water a brownish-jellow solution is formed, which, however, in a very short time becomes warm and the fluoride decoming the salt of the salt very snort time occomes warm and the mortice accomposes; platinic hydrates precipitated, and freehydrofluonic acid remains in solution. If the quantity of water is greater, the solution may be preserved for some minutes without dicomposition. If the liquid is boiled, it decomposes instantly At a red heat platinic fluoride decomposes into metallic platinum and fluorine, which is evolved in the free state. This reaction can therefore be employed as a ready means of preparing fluorine, the fluoride only requiring to be heated rapidly to redness in a platinum tube closed at one end, when crystallized silicon held at the open end will be found to immediately take fire in the escaping fluorine. The best mode of obtaining the fluoride of platinum for this purpose is to heat a bundle of platinum wires to low redness in the fluor-spar reaction tube in a rapid stream of fluorine. As soon as sufficient fluoride is formed on the wires, they are transferred to a well-stoppered dry glass tube, until required for the preparation of fluorine.

ACTION OF FIUORINE UPON NON-METALLIC COMPOUNDS

Sulphuretted hydrogen -- When the horizontal tube shown in Fig. 3 is filled with sulphuretted hydrogen gas and fluorine is allowed to enter, a blue fiame is observed on looking through the fluor-spar windows playing around the spot where the fluorine is being admitted. The desulphide is converted into gaseous fluorides of hydrogen and sulphur.

Sulphur droxide is likewise decomposed in the cold, with production of a yellow flame and formation of fluoride of sulphur

Hydrochloru acid gas is also decomposed at ordinary temperatures with flame, and, if there is not a large excess of hydrochloric acid present, with detonation Hydro-fluoric acid and free chlorine are the products Gaseous hydrobromic and hydrodic acids react with

fluoribe in a similar manner, with production of flame and formation of hydrofluoric acid Inasmuch, however, as bromine and iodine combine with fluorine, as previously described, these halogens do not escape, but burn up to their respective fluorides. When fluorine is delivered into an aqueous solution of hydriodic acid, each bubble as it enters produces a flash of flame, and if the fluorine is being evolved fairly rapidly there is a series of very

violent detonations A curious reaction also occurs when fluorine is similarly passed into a 50 per cent aqueous solution of hydrofluoric acid itself, a flame being produced in the middle of the liquid, accompanied by a carine of detonations

Nitric acid vapour reacts with great violence with fluorine, a loud explosion resulting If fluorine is passed into the ordinary liquid acid, each bubble as it enters produces a flame in the liquid

Ammonta gas is decomposed by fluorine with forma tion of a yellow flame, forming hydrofluoric acid and liberating nitrogen. With a solution of the gas in water, each bubble of fluorine produces an explosion and flame. as in case of hydriodic acid

Phosphoric anhydride, when heated to low redness, burns with a pale flame in fluorine, forming a gaseous mixture of fluorides and oxylluoride of phosphorus. Pentachloride and trichloride of phosphorus both react most energetically with fluorine, instantly producing a brilliant flame, and evolving a mixture of phosphorus pentafluoride and

free chlorine

Arsenious anhydride also affords a brilliant combustion, forming the liquid trifluoride of arsenic, AsF. This liquid in turn appears to react with more fluorine with considerable evolution of heat, probably forning the pentafluoride, AsF. Chloride of arienc, AsCl, is converted with considerable energy to the trifluoride, free chlorine being liberated

Carbon bisulphide inflames in the cold in contact with Careen as in parameter in the could in contact with fluorine, and if the fluorine is led into the midst of the fluoring a similar production of fixme occurs under the surface of the liquid, as in case of nitric acid. No carbon is deposited, both the carbon and sulphur being entirely converted into gaseous fluorides.

Carbon t. trachloride, as previously mentioned, reacts only very slowly with fluorine The liquid may be saturated with gaseous fluorine at 15°, but on boiling this liquid a gaseous mixture is evolved, one constituent of which is cirbon terafluoride, CF4, a gas readily capable of absorp-tion by alcoholic potash. The remainder consists of another fluoride of carbon, incapable of absorption by potash, and chlorine A mixture of the vapours of carbon tetrachloride and fluorine inflames spontaneously with detonation, and chlorine is liberated without deposition of carbon

Boric anhydride is raised to a most vivid incandescence by fluorine, the experiment being rendered very beautiful by the abundant white fumes of the trifluoride which are

Silican diaxide, one of the most mert of substances at the ordinary temperature, takes fire in the cold in contact with fluorine, becoming instantly white-hot, and rapidly disappearing in the form of silicon tetrafluoride The chlorides of both boron and silicon are decomposed by fluorine, with formation of fluorides and liberation of chlorine, the reaction being accompanied by the production of flame.

ACTION OF FLUORING UPON METALLIC COMPOUNDS.

Chlorides of the metals are instantly decomposed by fluorine, generally at the ordinary temperature, and in certain cases, antimony trichloride for instance, with the appearance of flame Chlorine is in each case liberated, and a fluoride of the metal formed. A few require heating, when a similar decomposition occurs, often accompanied by incandescence, as in case of chromium sesquichlbride.

Bronudes and rodides are decomposed with even greater energy, and the liberated bromine and iodine burn in the fluorine with formation of their respective fluorides

Cyanides react in a most beautiful manner with fluerine, the displaced cyanogen burning with a purple flame. Potassium ferrocyanide in particular affords a very pretty

NO. 1148, VOL. 447

experiment, and reacts in the cold Ordinary potassium cyanide requires slightly warming in order to start the

combustion.

Fused potash yields potassium fluoride and ozone. Aqueous potash does not form potassium hypofluorite when fluorine is bubbled into it, but only potassium fluoride Lame becomes most brilliantly incandescent. owing partly to the excess being raised to a very high temperature by the heat developed during the decomposition, and partly to the phosphorescence of the calcium fluoride formed.

Sulphides of the alkalies and alkaline earths are also immediately rendered incandescent, fluorides of the metal

and sulphur being respectively formed.

Boron nutrade behaves in an exceedingly beautiful manner, being attacked in the cold, and emitting a brilliant blue light which is surrounded by a halo of the fumes of

boron fluoride

Suiphates, nitrates, and phosphates generally require the application of more or less heat, when they too are rapidly and energetically decomposed Calcium phos-phate is attacked in the cold like lime, giving out a brilliant white light, and producing calcium fluoride and gaseous oxyfluoride of phosphorus, POF, Calcium carbonate also becomes raised to brilliant incandescence when exposed to fluorine gas, as does also normal sodium carbonate, but curiously enough the bicarbonates of the alkalies do not react with fluorine even at red heat. Perhaps this may be explained by the fact that fluorine has no action at available temperatures upon carbon dioxide

ACTION OF ILUORINF UPON A FEW ORGANIC COMPOUNDS.

Chloroform - When chloroform is saturated with fluorine, and subsequently boiled carbon tetrafluoride, hydrofluoric acid and chlorine are evolved. If a drop of chloroform is agitated in a glass tube with excess of fluorine, a violent explosion suddenly occurs, accompanied by a flash of flame, and the tube is shattered to pieces. The reaction is very lively when fluorine is evolved in the midst of a quantity of chloroform, a persistent flame burns beneath the surface of the liquid, carbon is deposited, and fluorides of hydrogen and carbon are evolved together with chlorine

Methyl chlaride is decomposed by fluorine, even at -23°. with production of a yellow flame, deposition of carbon, and liberation of fluorides of hydrogen and carbon and free chlorine With the vapour of methyl chloride, as pointed out in the description of the electrolysis, violent explosions occur

Ethyl alcohol vapour at once takes fire in fluorine gas, and the liquid is decomposed with explosive violence without deposition of carbon. Aldehyde is formed to a considerable extent during the reaction.

Accts aced and bensene are both decomposed with violence, their cold vapours burn in fluorine, and when the latter is bubbled through the liquids themselves, flashes of flame, and often most dangerous explosions, occur. In the case of benzene, carbon is deposited, and with both liquids fluorides of hydrogen and carbon are evolved Amisne likewise takes fire in fluorine, and deposits a large quantity of carbon, which, however, if the fluorine is in excess, burns away completely to carbon tetrafluoride.

Such are the main outlines of these later researches of M. Moissan, and they cannot fail to impress those who read them with the prodigious nature of the forces associated with those minutest of entities, the chemical atoms, as exhibited at their maximum, in so far as our knowledge at present goes, in the case of the element fluorine.

A. E. TUTTON.

THE HUXLEY LABORATORY FOR BIOLOGICAL RESEARCH, AND THE MARSHALL SCHOLARSHIP

SCIENTIFIC friends and former pupils of Prof Huxley will alike be gratified to learn that an appropriate method has been devised for establishing a permanent memorial of his great services to the insti-tution with which his name has been so long identified The late Sir Warington Smyth, whose loss we had to de-plore rather more than a year ago, was the last surviving member of the original staff of the School of Mines, as founded by Sir Henry de la Beche in 1851. Prof Huxley, who, as long ago as 1854, succeeded Edward Forbes in the Chair of Natural History, continues to hold the post of Honorary Dean of the Royal College of Science, with which the School of Mines is now incorporated, and although, since 1885, compelled by ill lealth to discontinue the work of lecturing, he is still, we are happy to say, able to take a kindly interest in, and to exercise a general supervision over, the biological studies carried on in the school

How much the Central Institution for training teachers in science, which is now located at South Kensington, owes to the organizing faculty and unremitting labours of Prof. Huxley, only those who have been associated with him in the work can form any just estimate During the first twenty years of its existence all attempts at practical teaching in the School of Mines were restricted to the subjects of chemistry and metallurgy, the space available in the Jermyn Street buildings only permitting of the existence of very small and inconvenient laboratories in

connection with those two branches of science.

Soon after the first establishment of the school, larger and more convenient premises for carrying on the chemi-cal instruction had to be obtained in Oxford Street, and in 18/2, on the unanimous recommendation of the Council, the teaching of chemistry, physics, and biology, was transferred to the building at South Kensington, which had been originally designed as a School of Naval Ar hitecture. At subsequent dates, as the inadequacy of the Jermyn Street buildings to accommodate both the school and the Geological Survey made itself more strongly felt, the divisions of geology, mineralogy, metal-lurgy, applied mechanics, and mining, were successively

removed to the same place.

No sooner did Prof. Huxley find an opportunity afforded to him, than he energetically devoted himself to the realization of a long-cherished scheme for establish-ing a system of practical laboratory-instruction in biology, including both its goological and its botanical aspects. The ground was broken by a short vacation course, in which an attempt was made to supply such practical instruction to persons engaged in teaching, this course was given in the summer of 1871, and in the following year the same system of laboratory-instruction in biology was introduced into the ordinary School of Mines curriculum In establishing at South Kensington the biological laboratory which has become the model of so many similar institutions at home and abroad, Prof. Huxley sought and obtained the advice and co-operation of many of his fellow-workers in science, among whom may be specially mentioned Profs Michael among whom may be specially mentioned Profis Michael Forcer, Thiselfon Dyer, Ray Lankester, and Rutherford, Forcer, Thiselfon Dyer, Ray Lankester, and Rutherford, Forcer, Thiselfond, The Lankester, and Rutherford, Forcer, Forcer,

bining original research with the work of teaching No one at the present day needs to be reminded of the mannerous important investigations which have been

prosecuted by Prof. Huxley, both at Jermyn Street and South Kensington Memoirs of the highest value on various branches of comparative anatomy and palæontology have been interspersed with notable contributions to geology, to anthropology, and to botany, and from time to time excursions have been made still farther afield (predatory excursions they were regarded by some), into realms of thought more remote from the ordinary domain of the zoologist But in all these varied avocations the interests of the teaching work were never forgotten; and it was made evident that the teacher, while carrying on investigations himself, was ever ready to suggest, stimulate, and supervise the investigations of others

When, in 1885, ill-health compelled Prof Huxley to relinquish his daily occupations in the school, it was found that, during the more than thirty years' occupancy of his post, he had accumulated a most valuable library of research, composed of treatises and journals dealing
with every branch of biological science This library he This library he generously determined to present to the institution, the interests of which he had so long and earnestly laboured to promote The Council of the School, in accepting this valuable gift, recommended that the room where these books were kept, and in which Prof Huxley had so long carried on his work, should be entirely set apart for biological research, and the proposal at once met with the

Lducation

The Huxley Laboratory for Biological Research is now arranged to accommodate twostudents, who will undertake botany, or palacontology, the work being carried on under the supervision of the professors and assistant professors of the school. With a valuable library and all necessary appliances for work supplied to them, it may be hoped that the genus loca will not be without its influence upon these research students, and that a long series of important observations may be made, which will constitute an enduring and a worthy memorial of Prof Huxley's connexion with the school

It happens, very opportunely, that something in the way of a small endowment has already been provided to and this scheme of biological research. As long ago as 1882, Miss Sarah Marshall, of Warwick Gardens, sington, wrote to Prof Huxley, informing him of her intention to bequeath the sum of Lioco, and her scientific books and instruments, to the Department of Science and Art, with a view to the establishment of a prize or scholarship in biology, in memory of her father, the late Mr Marshall of the Bank of England By the recent death of Miss Marshall, this bequest has now passed into the hands of the Lords of the Committee of Council on Education, and, by the advice of the Council of the Royal College of Science, it has been decided that the interest of the legacy shall be annually paid as a scholarship to a meritorious student, to aid him in carrying on some biological investigation in the Huxley Laboratory. only hope that this modest attempt at the endowment of research may be attended with success, and that this success may be so conspicuous as to encourage others to imitate the example of Miss Marshall, so that bequests of a similar character may be made in connexion with this and other institutions where scientific researches can be carried on

ON VAN DER WAALS'S TREATMENT OF LAPLACE'S PRESSURE IN THE VIRIAL EQUATION; IN ANSWER TO LORD RAY-LEIGH.

MY DEAR LORD RAYLEIGH, -- From the heading of your first letter, and from the wide scope of the passage you quoted from my paper, I imagined that you intended to raise the whole question of Van der Waals's

treatment of Laplace's pressure. Otherwise I should not, in my answer, have referred to his \(\tilde{\ell} \) or to the unfortunate results of comparing his formula with experiment. I should, in fact, have contented myself with the acknowledgment that you had given an accurate account of the contents of a portion of Van deer Waals's earlier chapters, which I had carelessly missed on the first hasty perusal, and that these contents justified the expression \(\tilde{\ell} \) for the principle of \(\tilde{\ell} \) and the time of \(\tilde{\ell} \) and that \(\tilde{\ell} \) for \(\tilde{\ell} \) and that \(\tilde{\ell} \) for \(\tilde{\ell} \) and that \(\tilde{\ell} \) for \(\tilde{\ell} \) for \(\tilde{\ell} \) in \(\tilde{\ell} \) and that \(\tilde{\ell} \) for \(\tilde{\ell} \) of \(\tilde{\ell} \) in \(\tilde{\ell} \) for \(\tilde{\ell} \) in \(\tilde{\ell} \) in \(\tilde{\ell} \) of \(\tilde{\ell} \) in \(\ti

For (1) that passage contains the distinct statement that, from the statical point of view, reasons "satisfactory on the whole" were given by Van der Waals for regarding Laplace's pressure as proportional to the square of the density. And it would have been illogical on my part to object, except on the ground of insufficient generality, to the equation

$$(p + \frac{a}{n!})v = \frac{1}{2}\Sigma(mu),$$

though I might have regarded the mode of its establishment as obscure or even doubtful,

In fact, the equation which is one of the main features of my own paper, viz.

$$pv + \frac{\Lambda}{v + a} = \frac{1}{2}\Sigma(mu') \left(1 + \frac{\epsilon}{v + a}\right),$$

includes it as the particular case when e = 0, a = 0

What I objected to was a totally different thing —viz the above equation manipulated by the introduction of the factor $(\nu - \delta)/\nu$ in the left-hand member Again (2) the equation

$$p(v - \beta) = \frac{1}{2}2(mu^2)$$

is obtained in my paper (§ 64), and is there spoken of as "perfectly legitimate," but only on the distinct condition

$$\beta \Xi (m u^2)/3 v$$

where β is four times the sum of the volumes of the particle (§ 20), "be small in unpharam with the other particle (§ 20), "be small in unpharam with the other hands of the quantity $\beta(u, b)$ states, this implies that for the truth of the quantin $\beta(u)$ must be a small fraction, and it is most certainly not so at the critical point of carbonic acid, which furnished the first and one of the most important cases for the application of the virial method. In fact the equation above, when correctly obtained, in fact the equation above, when correctly obtained, preserved) must be form (in which it cought to be preserved).

$$pv = \frac{1}{3}\mathbb{I}(mu) \left(1 + \frac{\beta}{\nu}\right);$$

again a particular case of my own equation, viz. when $A = 0, \quad a = 0, \quad c = 8$

Here the factor (m, m) is using the property of the factor (m, m) is the factor (m, m) in the capacity that is appears in the equation. At I and that capacity that is appears in the equation. At I and in my former letter, it is impossible (at least with Van der Waals's mode of interpreting $X(mu^n)$) to derive from this cubic (m, m) is even when the term ab^n is introduced as a cubic (m, m) cere when the term ab^n is moduced as a cubic (m, m) in the constant (m, m) in the constant (m, m) is (m, m) in place of (m + b) (m, m), and (m, m) is (m, m) in place of (m + b) (m, m) in right-hand side, which is, practically, what (m, m) is (m, m) is (m, m) in the constant (m, m) in the constant (m, m) is (m, m) in the constant (m, m) in the constant (m, m) is (m, m). This can, to a certain each at least, be justified, the other method can not.

On the question of the introduction by Van der Waais of the factor $(\nu - b)/\nu$, whether or not it is applied alike to

and to K. I regret to find that our views must continue to differ For it appears to me that when once the various terms of the virial equation have been correctly extracted from the expression Z(Rr), we have no right to modify any of them. There seems therefore to be no doubt whatever that the procedure in Van der Waals's sixth chapter is entirely wrong in principle -except in so far as (in the German version) he borrows some correct expressions from Lorentz. The meanings of v and of p, in the term po of the virial equation, are (from the very beginning of the inquiry) definitely assigned as total volume and external pressure .- so that this term cannot in any way be altered No more can the term 2(mu2)/3, or the ratio of these two terms Van der Waals's argument seems (for his pamphlet is everywhere somewhat obscure) to be that nis paintinct is everywhere somewar obscure; to be that when there is no molecular force) in consequence of the finite diameters of the particles the pressure, for a given amount of kinetic energy, and the greater than if these ware more points. Perfectly true—but we must seek the expression for this increase of pressure in the remaining expression for this increase of pressure in the remaining parts of the term x(Rr), and mot artificially introduce it by diminishing the multiplier of p in a term already definitely extracted. And further, if this procedure of Van der Waals were allowed to pass without protest in so far as the term pv is concerned, 1 think that we should logically be forced to treat the term Kv (not to the same but) to a very different factor :- for here the consideration of the finite volumes of the particles would appear to call for a reduced rather than an increased value of K : and therefore analogy would require a multiplication of the term Kv by some such expression as $(v+\gamma)/v$, where γ is essentially positive -- Yours very truly,

Edinburgh, 17/10/01

NOTES.

To-ray the Senate of Cambridge University will details whether official inquiry shall be made as to the expediency allowing alternatives for one of the voc classical languages in the most of the state of the control of the state of the

Tite ordinary general meeting of the Institution of Mechanical Engineers began yesterday evening, and will be continued this evening, at 25 Great George Street, Westminster. The papers to be read and discussed, as we have already stated, are by Mr. Samuel Bawell and Prof W. C. Roberts-Austen, F. R.S.

THE Geologist's Association will hold a conversatione at University College, Gower Street, on Friday evening, November 6 Members are invited to send exhibits, and to let the accretary know the nature of the object or objects they propose to show.

Ar the meeting of the Royal Horticultural Society in the Poli Hall, Westimater, or Tuesday, there was an interesting duplay of autumn foliage arranged for authent effect. A lecture was delivered by Mr H. J. Vetch, who urged that trees and alreads an gardens and plantations should be selected, not only with a view to their autumner besury, but also with regard to only with a view to their autumner besury, but also with regard to the various ways in which these hasts may be most effectively contrasted

PROF. BOYS has arranged his apparatus for the repetition of the Carendish experiment in the basement of the Clarendon Laboratory, Oxford. The experiment will be proceeded with immediately.

WE regret to have to record the death of Dr. Philip Herbert Carpenter, F R.S., the fourth son of the late Dr. W. B. Carpenter, CB, F.RS He was found dead in his dressingroom at Eton College, on Wednesday, October 21 At the inquest it was found that he had killed himself by the administration of chloroform during temporary insanity Dr Carpenter was in his fortieth year, and had been a science master in Eton since 1877. The following summary of his scientific work in given by the Times. He was a member of the scientific staff of the deep sea exploring expeditions of Her Maiesty's steamships Lightning (1868) and Percupine (1869-70), and in 1875 he was appointed assistant naturalist to Her Majesty's ship Valorous, which accompanied Sir G. Nares's Arctic expedition to Disco Island, and spent the summer sounding and dredging in Days Strait and the North Atlantic Dr. Carpenter devoted himself continuously from 1875 to studying the morphology of the Echinoderms, more particularly of the Crinoids, both recent and fossil In 1883 he was awarded the Lyell Fund by the Geological Society of London in recognition of the value of his work, and in 1885 was elected a Fellow of the Royal Society His chief memoirs and papers were as follows -" Notes on Echinoderm Morphology," 1-x1, 1878-87, "On the Genus Actinometra," 1877, "Report upon the Crinoidea dredged hy H.M.S Challenger," Part I "The Stalked Crinoids," 1885, Part Il "The Comatule," 1888; "Report upon the Comatulm dredged by the U S Coast Survey in the Caribbean Sca," 1890. In conjunction with Mr. R Etheridge, Jun., he prepared the "Catalogue of the Blastoidea in the Geological Department of the liritish Museum," 1886, and he also wrote numerous papers published in the Proceedings or Transactions of the Royal, Linnean, and Geological Societies

MR. GEORGE SIBLEY, who was for many years well known as an engineer in India, and had also n considerable reputation as a traveller, ided at his residence at Catherham on Sunday last at the age of ixiy seven. It is understood that Mr. Sibley has left a legacy for the purpose of founding engineering scholar-shaps in the University of Calcutte.

DA J. EDUARD POLAK, who died at Vienna on October 8, at the age of sevenity one, was one of the most enamel Persans cholars of his time. He went in 185 to Teheran, where he level at the medical school, and became physician to the Shah. Daring his nine pears' seudence in Persan he visited most part in of the country, and on his return to Vienna he work in well-known work, "Persano, das Land und seine Bewohner," in which he pre-ented an excellent aummary of the knowledge he had sequired. In response to an invitation from the Shah, he again wisted Teheran. He read before the Geographical and Anthropological Societies of Vienna many valuable papers on Persan and its antiquates.

THE International Geological excursion in America, which started on September 2 last, ended on October 9 after a most successful and interesting trip. In all there were ninety geo logists, and the arrangements as regards trains, &c., left nothing to be desired. The route chosen lay through the petroleum districts of Pennsylvania, the praines of Wisconsin, Minnesota, and Dakotah, the corn-lands of North America, and the twin centres St Paul and Minnespolis. From the Yellowstone River the party journeyed to the beautiful geyser region of the National Park, where they made a stay of seven days, then to the rising mountain district of Butte, as well as to the Mormon town situated in the middle of the salt wastes of the Great Salt Lake. They then skirted the table-lands in South Utah, and turned towards the Rocky Mountains, where they visited the chief places of geological laterest, including Pike's Peak, the Garden of the Gods, &c At this point many of the party returned home, going by way of Chicago, Niagara Falls, and New York. The smaller number that remained undertook a laborious and exhausting expedition through the deserts of New Mexico and Arisona to the San Francisco mountains and to the Grand Calino of Colorado, they visited a group of 165 volcances and craters, and also a deep valley the sales of which, with their many and varous coloured stones, fall 360 to 6000 feet to the great Colorado River below From this standpoint they had an excellent view of the materials composing the upper surfaces of the earth's crust, and they could not but be struck by the magnitude and grandeur of the work accomplished by Nature in digging out the enormous river calono. The following are some of the places visuated on the return journey. La Jinta, Kaisasa City, Chicago, Niagara Falls, Albany, and Boston. Allocghethe the excursion was a thorough success, and the Amencana deserve much credit for having arranged so good a programme for their visitors.

PROF RUSEIL and his party have returned from the Alaska wide, which they penetrated to a distance of forty miles inland, from Iry Bay to the base of Mount St. Eliast. They constructed a camp, and remainer there two months, making geological surveys and taking observations. Prof. Rassell assi—"We began the ascent of Mount St. Elias on Jane 3. Our progress was not obstructed until we reached an attitude for early 10,000 feet. There we found glacers. After many persions attenuers we attenued the baself contraction of the condition of the condition

THE report by Mr. James Dredge and Sir. Henry Trueman Wood on their recent with to Cheego us printed in the Journal of the Society of Aris (October 2). Thu report was presented ast week to the Royal Commission which his been appointed to organize the English Section at the Chicago." World's Fair." The Commission have devided to appoint the following Committees: Finance, Fine Aris, Indian, Colomal, Eugmeering, Ceneral Manufactures, Fletericity, Agriculture, Mines and Metallurgy, Lextle Industries, Science and Education, Transportation, also a Committee of Leddes to Correspond with the Ladest Committee at Chicago. They propose to invite the assistance of Chamberts of Commerce as Local Committees. A prospectize relating to the Chicago Exhibition has been issued by the Royal Commission.

THE Council of the Institution of Civil Engineers have issued for general circulation their regulations as to the admission of students. This is followed by an excellent account of the various educational institutions in the British dominions where instruction is given bearing on the profession of civil engineers.

In his report on the working of the Central Museum, Madras, during 1890-91, Mr Edgar Thurston, the Superintendent, notes that he made two official tours in company with his taxidermists During the first of these, as in several previous years, he stayed on Ramesvaram Island, where he was mainly engaged in the collection and preservation of marine worms and molluscan shells, which have since been sent to England and Germany to be worked up Many specimens of the brightly coloured "coral-fishes," which abound over the fringing coralreefs, were also preserved by the glycerine process introduced by Mr. A. Haly, of the Colombo Museum, for the preservation of colours. His stay on Ramesvaram Island completed, he paid a short visit to Tuticorin, to work out some doubtful points in connection with the anatomy of the pearl oyster. In his second. tour he made large collections illus rative of the arts, industries, manufactures, and natural history of the places visited in the Bangalore, Hassen, Shlmoga, and Mysore districts. These collections include Srávanbelgola brass-ware, Soráb and Sagar

sandal wood carring, Channapatna silk and toys, Mysore inlaid ware, gold jewellery from Beliur, batterfles, lizards, nakas, &c. A report on tha tour will be published after a farther vant to the Mysore province, a large area of which remains to be explored.

THE other day, Mr Flinders Petrie delivered at the Owens College. Manchester, a most interesting address on exploration in Egypt. It had been thought, he said, that the immense mounds of rubbish indicating the sites of towns had been made on purpose, but they resulted from the natural decay of the mad-brick buildings. These heaps of runed walls and earth and potsherds rose even to eighty feet high in some places; but other ancient sites were much less imposing, and might even not attract notice on the open desert The higher the mound the tonger the place had been inhabited, and if the surface was of a late period, the earlier parts, which were most needed, were under such a depth of rubbish as to be practically maccessible Much could be known at first sight, and prospecting had now become as scientific a matter in antiquities as in geology Knowing, by a glance at the sherds on the top, what was the latest period of occupation of the site, and knowing the usual rate of accumulation of a mud-brick town-about five feet in a century -- we could guess how far back the bottom of the mound must be dated. Other remains had different indications. If in the midst of a great mound there was a wide flat crater, that was probably the temple site, surrounded by houses which had accumulated high on all sides of it Speaking of the results of exploration. Mr Petrie said that we now realized what the course of the arts had been in Egypt In the earliest days yet known to us-about 4000 B C .- we found great skill in executing accurate and massive stonework, such skill as liad hardly ever been exceeded We found elaborate tools used, jewelled saws and tubular drills. We saw the pictorial arts as fully developed as they were for thousands of years later But what led up to this we were still feeling for.

To what uses did primitive men apply the stone haum which they made in such large numbers? This question Mr. J D McGuire tries to answer in a paper in the American Authiopologist for October 11is theory is that the liammer was probably "the tool upon which races living in the Stone Age celled more than upon any other object to fashion stone implements " It was used, he thinks, not only to peck an axe or celt into shape, but to rub or polish the implement after it had been shaped, and, to illustrate this, he gives a figure representing a typical hammer of quartzite, from McMinn County, Tennessee, the periphery of which is pitted by use, while the flattened sides show that it must have been a rubbing stone as well To prove that the work suggested could be done by a stone hammer, he represents an axe of close-grained black porphyry, which he himself pecked out and grooved by means of such an implement. The task occupied him about five hours. As ordinary stone axes are made of softer material, he thinks they were probably produced in a much shorter time,

Ds. H vost WitsLockti contributes to the current number of Chibuta a supplied paper on the handlerfish of Hungarian gypties, whom he has had many opportunities of observing. If we may judge from the illustrations, they have a considerable aptitude for dengn in the summer they make bottles out of prompkins, which they decorate with various drawings. On cut into the uppermost sone, serpents into the second one, circles into the third, and signs lines into the footh. The crosses mean "May you be happy it", the serpents, "May you have no occurse it", the crickes, "May you always have money!" the signs lines, "May you be healthy!" Brandy is kept in the bottle; a nod when a great in excerved, the

first gypsy who drinks says, "May you be happy !"; the second, "May you have no enemies!"-and so on, Pretty walkingsticks are also among the things made by the Hungarian gypsies. On the top of one of those sketched in the article two female heads are admirably carved. These represent Ana, the Queen of the Keschalyis, or forest fairies, who dwell among the mountains, where they sit-three being always togetheron rocks, spreading out their long hair over the valleys, thus giving rise to mists. Queen Ana lives in a black palace, and sometimes wanders over the world in the form of a frog. Frogs, toads, and serpents are her favourite animals. When she meets anyone in her natural form, she exclaims "Ana!" which means "Bring!" Should the person understand the cry and bring a frog. a toad, or a serpent, he is richly rewarded If he fails to do so, he is either killed with a piece of a rock, or struck by some terrible malady

THF Times of October 22 has an interesting article on "Our Position with regard to Rainfall," compiled from the statistics published by Mr. Symons and the Meteorological Office The rainfall during the present month has been so heavy that In many places the amount up to the morning of the 18th was in excess of the average for the whole month In London this excess amounted only to o 3 inch, while at Valentia Island and at Stornoway it amounted to nearly 2 and 3 inches respectively, and the amount which fell during the next few days has greatly increased the excess. But for the to years ending with 1830 the rainfall over the United Kingdom differed only by t per cent from the average of the last 50 years. The values for the present year, up to the 18th Instant (as shown by the last Weekly Weather Report then published), were rather in excess of the average over the southern, midland, and western parts of England, and the north of Scotland, while in the re maining districts there was still a deficiency. For the whole period since the end of 1880, there was only one district, viz. Scotland (N). in which the total fall was in excess of the average. In Scotland and the midland and south-western counties of England, the deficiency was still very large The question is asked-Are we likely to have in the years immediately advancing more or less rain than during the last few years? While the question can not be answered with absolute confidence, the grouping of years into decades or other regular periods eliminates most of the non periodic variations, and shows whether any secular alterations are taking place. There is no doubt that since 1887, at all events, the rainfall over England has been much below the average; and a consideration of all the facts leads to the conclusion that such a period of scarcity is very likely to be followed by one of abandance, and that the coming few years will probably be more rainy than those recently experienced, although possibly the increase will not occur in the summer months-at a time when it would be most noticed.

THE new number of Petermann's Mitthinugen opens with some interesting extracts from the diary of the late Dr. Anton Stecker, written during his journey in Alysania and the Galla contines in 1850-83. Stecker dide before he had an opportunity of writing a full and systematic account of his irrevial. In the present extracts he notes not only the physical characteristics of the regions to which they relate, but the manness reader to trace this route.

A GREEK guidencr lately expressed the opinion that oranges, figs, olives, and grapes grops in Australia are inferior to those grown at Smyrna and Athens. This having been brought to the attention of the Department of Agriculture, New South Wales, letters were addressed to the British Consuls at Naples and Marseilles saking for a consignment of the best varieties of grapes, figs, and olivies grown in Italy and France. On receipt of these

cutings, experiments are to be carred out at the most saliable of the experimental stations should to be established throughout the colony, with a view to the propagation of the finest wanettee of the respective fruits. With the same object in vew application has been made to Mr. T. Hardy, of South Australia, for a number of extinge of various vines be has cultivated, and to Sir Samuel Davenport, of Reaumont, South Australia, for cuttings of the olive and fig treet grown by him. The whole of these of the olive and fig treet grown by him. The whole of these different kinds of fruit which it is mineded to establish at each of the experimental stations.

In the Revue Agricole, published in Mauritius, M. A. Daruly de Grandprégives an account of his attempts to raise sugar cane from seeds. The seeds were sent from Barbados by the Governor in March 1890 M de Grandpie planted them with the greatest care, and after five days was fortunate enough to obtain five minute seedlings out of the hundred seeds used The young plants he raised did not all prove equally vigorous, and he was able to save only one, which, at the time when his report was written, had formed a fine clump of twenty shoots with long ribbon leaves. "I believe," he says, "that we may with reason cherish the most sanguine hopes from the propagation of sugar cane from seeds-more especially if we try an intelligent system of cross-fertilization of the varieties we possess-rather than by planting cuttings, which maintain without appreciable alteration the respective characteristics of the parent plants. Thus we shall be able to supplement the weak points in our best varieties of sugar-cane by crossing them with others which are remarkable for the qualities it is intended to infuse into them, and we shall moreover obtain, by a process of selection, a cane rich in saucharine matter, which will enable us to compete successfully against the highly improved sugar-beet."

Ms. A. W. MORRIS contributes to the current number of the Journal of the Bombay Natural History Socsety an interesting paper on abnormal horas of the Indian anticlope. We have as well little definite information as to the cause or causes of such abnormalities. Mr. Morris suggests that severe injuries to the skull, inflicted either during hattie or through some seculent, are the main causes that produce abnormalities, the horn on the causion of themse a tustantool. Or in natural course by the concusions of efames rustantool.

THE Academy of Natural Sciences of Philadelphia prints in its Proceedings a list of the Echinoderms obtained by Mr. Frederick Stearns, of Detroit, in the Bahama Islands in the years 1887 and 1888. The list has been drawn up by Mr. J. E. Itsell Litelludes a description of a new species of Amphura

A VALUABLE revised list of British Echinoidea, by Mr William E. Hoyle, has been printed in the Proceedings of the Royal Physical Society, Edinburgh, and is now issued separately. The author gives a brief diagnosis of each species, such as will enable the collector to identify in on the spot.

MESSEX, J. AND A. CHUKCHILL have published a second edition of the Engish transition of Dr. A Chauvers's "Comparative Anatomy of the Domesticated Animals." Dr. George Fleming is the transitor and editor. In preparing the new edition, Dr. Fleming has kept in view the accessities of al, vancing veteransy education in the Engish-speaking schools. He has introduced, therefore, a considerable number of "amendments, alteration, and additions".

MESSES. HENRY SORHERAN AND CO. propose to issue a work entitled "Game Birds and Shooting Sketches," by J. G. Millais, F.Z. S. The work will illustrate the habits, modes of capture, and stages of plumage of game birds, and the hybrids and varieties which occur among them

NO. 1148, VOL. 44]

THE University College of North Wales has issued its Calendar for the year 1891-92

LECTURES on the following subjects will be given at the Royal Victoria Hall on Tuesday evenings during the month of November ...—November 3, Mr F. W. Rudler, "Some Very Ancient Britons", November 10, Dr Rideal, "London Fogs", November 17, Dr W. D. Hallbutton, "Skin and Bones" (second lecture), November 24, Rev C E Brooke, "A Holday in the Far West"

Titz additions to the Zoological Society's Gardens during the past week include a Winter fronti-Leurus (Leurus algebras algebras 1) from Madagascar, presented by Mr. J. M. Nicholl, a Ring-land Coats (Masser step) from South America, presented by Mr. J. M. Nicholl, a Ring-Beropean, presented by Mr. Lower Harry E. Z. S., two Common Cuckoos (Cuesture cannorsh, British, presented respectively) by Mr. II. Landay and Miye Orl. a Burbot (Labe welgarray). From the Trent, presented by Mr. F. T. Barrows, a Macaque Monkey (Massers symmolique 4) from India, a loud Marmost (Madar renalsa) from South-Least Brard, an Australian Cassowary (Cussarras cantalsa) from Mautrials, deposited

OUR ASTRONOMICAL COLUMN.

THE ZODACAL LIGHT AND ALKNOW — On he supportion that the zodacat light is an extremo of the solar corona, and that the latter munity consust of light reflected from mettorities to the plane of the equator, My, M. A. Veeder explain (Rochester Academy of Sciences, January 26, 1891) why modile [Antieste the phenomenous hugglest in March and modile [Antieste the phenomenous hugglest in March and sunnite, and also the fact that at these times one margin of the modile and the period of the solar period of autore and magnetic period of the solar period of autore and magnetic period of the solar period of autore and magnetic period of the solar period of autore and magnetic period of the solar period of autore and magnetic period of the solar period of autore and magnetic period of autore and autore

coercising originates, and not neight neconic all continues contracting originates, and not neight neconic all continues or the turbations shows that they may be arranged in periods having the same length as that of a synodic rotation of the sun. And it appears that the areas issued frequencied by sun spots are most that a spear that the areas issued frequencied by sun spots are most research, Mr. Vecker believes that the held the distribution of atmosphere, bessues about the magnetic pole as a centre is very sincely dependent upon magnetic induction of solar volcanic origin, conveyed from the suit to the earth through the medium origin, conveyed from the suit to the earth through the medium

CONET c 1891 —The following orbit has been computed by Prof. Campbell for the comet discovered by Prof. Barnard on-October 2 —

On October 30 the comet is in the position R.A 10h. 53m 7s, Decl - 54° 43' It is therefore not visible in our latitudes

Two New Asperoids —A new minor planet, (ais), of the thirteenth magnitude was discovered by M. Charlois on October 8, and another, (as), by Dr. Palisa on October 11

The latter observer has given the name of Thora to (200), Olga to (201), and Fraternitas to (201).

DOUBLE STARS—M. S W Burnham announces that he is preparing a general catalogue of all the double stars discovered by him, and would be glad to receive any unpublished measures of them, Nos. 1 to 1224.

JUPITER'S FIRST SATELLITE.—Some recent observations made at Lick Observatory show that the first satellite of Jupiter is ellipsoidal, and that one of its longer axes is directed to the plane's courte.

THE INTERNATIONAL METEOROLOGICAL CONFERENCE

THIS meeting, which was more or less of a private character, as it was not organized in any way through diplomatic channels, took place at Munich from August 26 to September 2. It was held in the building of the Technical High School, and was attended by 32 members, representing most European and some extra European countries As to the latter, the United States contributed four members, while Brazil and Oueensland States contributed four members, white Brazil and Queenaland sent one each Koumania and Bulgaria for the first time took part in one of these meteorological gatherings Dr. Ilang, the head of the Bawarian meteorological system, was appointed President, and Prof. Mascart (Paris) with Prof. Harrington (Washington) Use-Presidents. The Secretairies were Dr. Erk (Washington) Vice-Presidents The Secretaries were I (Munich), Mr. Scott, and M. Teisserene de Bort (Paris)

The following is a brief summary of the most important mentact insulation of recommendations of the Conference.

All temperatures pull-thind after 1500 rate to be referred to the readings of the art thermometer Actionmetrical observations are not held to be sufficiently certain to justify their general control of the process of the conference of the con A report was also received and adopted on the arrangement. A report was also received and adopted on the observation of the motions, &c., of cirrus and other high-level clouds. Wend —Robinson's anemometer was the only form of clouds. Wind—Robinson's anemometer was the only form of instrument discussed. It was decided that no instrument results should be published unless the instrument had been previously compared with a standard, either directly or indirectly. Time.—A proposal to recommend the adoption of directly, Jim.—A proposal to recomment the anoption of universal or zone time was emphatically rejected, on the ground was further decided in all publications to insist on commencing the day with andinght as o hours. Granup correction—It was decided to introduce the practice of correcting barometrical readings for the force of gravity at lat. 45° after the beginning

readings for the force of gravity at lat. 45° after the beginning of the year 1501.

SOCIETIES AND ACADEMIES. PARIS.

Academy of Sciences, October 19.—M. Duchartre in the chair—Memoir on the underground temperatures observed at the Muséum d'Histoire Naturelle, duning the winter 189-91, by M. Henri Becquerel. A thermo-electric arrangement was used for the determination of the temperatures beneath two used for the determination of the temperatures beneath two surfaces, one of which was covered with sand and devoid of vegetation, whilst the other had greas and some plants growing upon it. The two solis were similar, and in each case the temperatures were taken at five points, having depthe ranging from November 1, 1890, to March 31, 1891, the temperatures being taken at 6 a.m. and 3 p.m. daily. These have been plotted, and the resulting curves stringing show the variations which coursed in the interval, and the extinction of detail with increased depth. The diarrial variation at the greatest depth was a few tenths of a degree, whilst that of the sit was shown to the contraction of the sit was shown to the contraction of the sit was shown to the site of the site

variation was the same as in air, but at all the other points the effect was reversed—that is, the temperature fell from 6 a.m. to 3 p.m., and rose during the night. It also appears from the observations that Fourier's theory of the differential relation existing between temperature, time, and depth of thermon existing between temperature, time, and depth of thermometer represents very well the propagation of heat in a superficial layer of soil, and that the coefficient of conductivity of this layer for determined conditions of humidity may be deduced from observations of underground temperatures. shi layer for determined conditions of humday may be decised from observations of undergroad teappearures. A certain thickness of earth protects the roots of plants of the control of the destroy the red corpuscies of the blood of another of a different destroy the red corpuscies of the blood of another of a different species. And the destructive power of serum for microbes is called. "pouvon microbicule". The effects produced in each case have been studied.—On the nature of the movement of the chromatophores of Cephalopods, by M. C. Phisalix,
